

Encyclopedia of
CREATIVITY

Second Edition

Volume I
A-I

How to go to your page

This eBook contains two volumes. In the printed version of the book, each volume is page-numbered separately. To avoid duplicate page numbers in the electronic version, we have inserted a volume number before the page number, separated by a colon.

For example, to go to page 5 of Volume 1, type 1:5 in the "page #" box at the top of the screen and click "Go." To go to page 5 of Volume 2, type 2:5... and so forth.

ABOUT THE EDITORS-IN-CHIEF

MARK A. RUNCO earned a Ph.D. in Cognitive Psychology from the Claremont Graduate School. His dissertation was on divergent thinking and he has studied creativity ever since. He founded the *Creativity Research Journal* over 20 years ago and remains Editor-in-Chief. He is currently the *E. Paul Torrance Professor of Creative Studies* at the University of Georgia, Athens. He is also Director of the *Torrance Creativity Center*, a *Fellow* and *Past President* of the American Psychological Association's Division 10 (Psychology of Aesthetics, Creativity, and The Arts). His textbook on creativity was released by Academic Press in 2007.

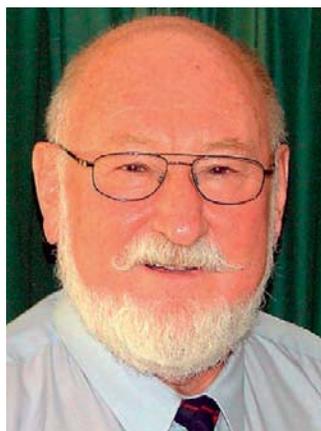

STEVEN R. PRITZKER, Ph.D., is Professor of Psychology at Saybrook University in San Francisco. He is Director of The Creativity Studies Certificate and Masters in Psychology with a Specialization in Creativity Studies. Dr. Pritzker writes both academic and popular press articles and books concerning creativity. He is a fellow and educational coalition representative for the American Psychological Association's Division 10 (Psychology of Aesthetics, Creativity, and The Arts). He serves on the editorial board of the APA journal *Psychology of Aesthetics, Creativity and The Arts*.

Dr. Pritzker is a former comedy writer-producer who worked on over 200 network television episodes including such popular shows as *The Partridge Family*, *Maude*, *Fish*, *The Hogan Family* and the Emmy winning *Mary Tyler Moore Show* and *Room 222*. He has received Emmy recognition and been nominated for the Writers Guild of America Award. Dr. Pritzker is President of Creativity Source where he consults and coaches organizations and individuals on maximizing their creativity.

ABOUT THE EXECUTIVE ADVISORY BOARD

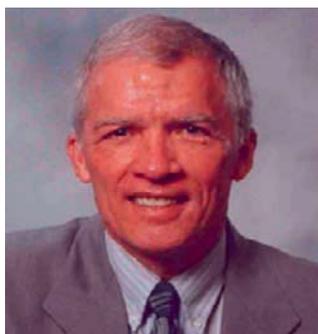

DAVID W. CHAN is a professor of educational psychology and the Program Director of the Program for the Gifted and Talented at the Chinese University of Hong Kong. He has published in areas that include stress and coping, psychopathology and health, creativity and intelligence, and gifted education and talent development.

ARTHUR J. CROPLEY spent several years as a school teacher before obtaining his Ph.D. in Educational Psychology at the University of Alberta (Canada) in 1965, and subsequently worked as a university teacher in Australia, Canada, Germany and Latvia. He retired in 1998. He is the author or editor of 25 books on creativity, lifelong learning, adaptation of migrants, and research methodology. These have appeared in English, German, Italian, Latvian, Spanish, Swedish, Norwegian, Danish, Hungarian, Korean, and Chinese. From 1989–1996 he was editor of the *European Journal for High Ability* (now known as *High Ability Studies*), published by the European Council for High Ability. He received the 1997 Creativity Award of the World Council for Gifted and Talented Children, and was elected Visiting Fellow of the British Psychological Society in 2004. In 2004 he received an honorary doctorate from the University of Latvia, and in 2008 he was made an Officer of the Order of the Three Stars by the President of Latvia, for services to higher education.

SANDRA W. RUSS, a child clinical psychologist, is a Professor of Psychology at Case Western Reserve University. She has served as President of the Society for Personality Assessment, of the Clinical Child Section of APA, and most recently, of Division of Aesthetics, Creativity and the Arts. Her research program has focused on pretend play, creativity, and adaptive functioning in children. She developed the Affect in Play Scale which assesses pretend play in children. Also, she and her students are developing a play facilitation intervention. She is author of *Affect and Creativity: The Role of Affect and Play in the Creative Process* (1993) and *Play in Child Development and Psychotherapy: Toward Empirically Supported Practice* (2004). She teaches the Child and Family Intervention course and a Psychology of Creativity course.

DEAN KEITH SIMONTON is Distinguished Professor of Psychology at the University of California, Davis. Although he earned his Harvard Ph.D. in social psychology, Simonton's research also encompasses developmental, differential, and cognitive questions. The majority of his studies apply historiometric methods to large samples of highly eminent creators. His bibliography lists nearly 400 publications, including 11 books, such as his 2009 *Genius 101*. Simonton is former president of the Society for the Psychology of Aesthetics, Creativity and the Arts (Division 10 of the American Psychological Association) and the International Association for Empirical Aesthetics. He is Fellow of the American Association for the Advancement of Science, Association for Psychological Science, International Association for Empirical Aesthetics, and nine Divisions of the American Psychological Association (1, 2, 5, 7–10, 20, and 24). His honors include the William James Book Award, the George A. Miller Outstanding Article Award, the Theoretical Innovation Prize in Personality and Social Psychology, the Rudolf Arnheim Award for Outstanding Contributions to Psychology and the Arts, APA Master Lecturer, the Robert S. Daniel Award for Four-Year College/University Teaching, and the Sir Francis Galton Award for Outstanding Contributions to the Study of Creativity.

ELLEN WINNER is Professor of Psychology at Boston College, and Senior Research Associate at Project Zero, Harvard Graduate School of Education. She received her Ph.D. in Psychology from Harvard University in 1978 working with Roger Brown on child metaphor. Her research focuses on cognition in the arts in typical and gifted children. She is the author of over 100 articles and four books: *Invented Worlds: The Psychology of the Arts* (Harvard University Press, 1982); *The Point of Words: Children's Understanding of Metaphor and Irony* (Harvard University Press, 1988); *Gifted Children: Myths and Realities* (BasicBooks, 1997, translated into six languages and winner of the Alpha Sigma Nu National Jesuit Book Award in Science); and *Studio Thinking: The Real Benefits of Visual Arts Education* (Teachers College Press, 2007, co-authored with Lois Hetland, Shirley Veenema, and Kimberly Sheridan).

She received the Rudolf Arnheim Award for Outstanding Research by a Senior Scholar in Psychology and the Arts from the American Psychological Association. She is a Fellow of the American Psychological Association (Division 10, Psychology of Aesthetics, Creativity, and The Arts) and of the International Association of Empirical Aesthetics.

JING ZHOU is Houston Endowment Professor of Management in the Jesse H. Jones Graduate School of Business at Rice University. She received her Ph.D. from the University of Illinois at Urbana-Champaign. Her current research interests include contextual factors that promote or inhibit employee creativity and innovation. She has published widely in top-tier journals in her field, and has co-edited (with Christina Shalley) *Handbook of Organizational Creativity*. Prior to joining the Jones School at Rice University, she was Associate Professor and Mays Fellow in the Management Department at the Mays Business School at Texas A&M University. She has served on editorial boards of top journals in her field, such as *Academy of Management Journal*, *Academy of Management Review*, and *Journal of Applied Psychology*. She is an incoming President of International Association for Chinese Management Research. Currently she is an associate editor of *Journal of Applied Psychology*.

PREFACE

When the first edition of *The Encyclopedia of Creativity* was published in 1999, creativity research had become broad and important enough to be treated as a legitimate field of scientific study. Since the first edition was published, interest in creativity has skyrocketed with more articles and books published than in the previous 40 years combined. This interest is an indication of the increasing complexity in our lives, where new ways of dealing with challenges on both individual and societal levels are essential. Creativity research is being conducted throughout the world in many different disciplines including psychology, arts and humanities, health sciences, education, and business. This global interest is reflected in the number of authors throughout the world who have contributed to this edition.

Some countries such as China, Korea, Singapore and New Zealand have made understanding, teaching, and encouraging creativity part of their national goals. Europe proclaimed 2009 the year of creativity. The leaders of these countries recognize that their primary natural resource is the ability of their citizens and organizations to develop new products and innovative concepts. As competition becomes more and more intense, the business community in the United States is finally accepting the concept that creativity can contribute directly to the bottom line. A recent poll of CEOs in the United States by IBM's Institute for Business Value indicated that creativity is the most important characteristic being sought in new executive hires. We have responded to the increased interest in the business community by including more entries on organizational creativity.

The *Encyclopedia of Creativity* is designed to inspire further recognition of the personal as well as professional benefits that accrue from encouraging creativity. We know, for example, that individuals who are more creative are healthier and more adaptive, and in some instances may even have a longer life expectancies. We also know that many innovations and ways of solving problems have already led to incredible benefits, such as cures for diseases, improved technologies, and higher living standards for billions of people. However, we are obviously losing a great deal of the creative potential on this planet by leaving so many of our children uneducated and unable to cope with the problems they face. Clearly we need new answers to such difficult problems as climate change, limited resources, religious and territorial conflicts, poverty, and energy.

If we want a more creative world, then we must construct an environment that allows creativity to flourish. This requires knowledge that crosses disciplines. The increased quantity and diversity of research continues for the most part to be focused on a specific area of interest. Most scientific research is still released only in academic journals. There is still not a broad cross-fertilization of knowledge that enhances the development of new ideas. One of the axioms in creativity research is that breakthroughs often occur when information or concepts from one field are applied to a different one. Darwin's theory of evolution was partially inspired by his reading Malthus' theory of population growth and Lyell on geological change. Jean Piaget, noted developmental psychologist, borrowed heavily from biology and epistemology. Freud used a medical model to understand the psyche. Our hope is that readers will roam outside their usual areas of interest in a search for new ways of thinking. The comprehensive nature of the encyclopedia offers readers the opportunity to find new perspectives, which we hope will suggest fresh insights about themselves, their work, and their place in the world.

In the first edition we stated that there was enough known about creativity that it could be integrated into every level of our educational system. Unfortunately "teaching to the test" has become more prevalent in the United States while arts programs have been all too often dropped. It is our hope that teachers at the elementary and high school level will learn about their own creativity and how to value and encourage students. It is not always an easy task, but it can help enhance and even save the lives of some creative students who are at risk.

Some progress is evident at the college and post-graduate levels where courses are taught in many schools throughout the country. There is still a tremendous need for degree earning programs and specializations in

creativity. The Torrance Center at The University of Georgia, Saybrook University, Buffalo State, and Drexel University are among the few schools that currently allow a specialization in creativity studies. By 2020 we hope that there are many more universities and professional schools which include courses and specialties in creativity studies.

Contents

Creativity is multifaceted and manifested in different ways in different domains. Moreover, there are different processes that can each lead to creative work. Thus a comprehensive *Encyclopedia of Creativity* required many different articles.

There are articles that present overviews of the research and theories about creativity from a variety of different areas:

- There are reviews of a number of domain-specific areas, such as acting, dance, expressive arts, film, food, music, religion, science, sports, theater, and writing.
- Creativity and education are examined in articles about thought processes, such as developmental trends in creative abilities and potentials, the enhancement of creativity, intelligence, knowledge, play, prodigies, programs and courses, talent and teaching creativity.
- Cognitive aspects of creativity can be investigated in articles about altered and transitional states, analogies, attention, cognitive style, divergent thinking, flow and optimal experience, metacognition, metaphors, problem-finding, problem-solving, and remote associates.
- Those interested in business and organizational creativity can view articles about advertising with art creative visuals, business/management, creativity coaching, creativity exercises, entrepreneurship, group dynamics, innovation, leadership, organizational culture, organizational development, teams, and training, among others.
- Many articles examine the creative process across domains, covering areas such as discovery, emotion/affect, gender differences, incubation, inspiration, insight, novelty and paradigm shifts.
- The complex interrelationship between society and creativity is explicitly examined in articles about awards, conformity and conventionality, the creative sector and class of society, cultural diversity, the dark side of creativity, East vs. West, networking, social psychology, war, zeitgeist, and others.
- Personal and interpersonal creativity is discussed in articles relating to collaboration, family, life stages, mentors, networking, personal creativity and self-actualization.
- Because the encyclopedia focuses on scientific information about creativity, there are also articles that discuss brain and neuropsychology, concepts of creativity, definitions of creativity, expertise, longitudinal studies, researching art, artists and art audiences, research methods, phenomenology research and qualitative research.
- Articles which look at theoretical perspectives include behavioral approaches, chaos theory, componential models, economic perspectives, the evolving systems approach, the four P's of creativity, and implicit theories.
- The creative process is examined in contrarianism, climate for creativity, discovery, dreams, heuristics, invention, motivation/drive, multiple discovery, novelty, time and rewards.
- Mental and physical health and creativity are reviewed in mental health: affective disorders, mad genius controversy, schizophrenia and psychosis, stress, suicide, and transforming illness and visual art.

Finally there are selected biographical studies selected with creativity as the key concern. The sampling of biographical subjects represents a much higher percentage of women in this second edition. Biographical subjects represent eminent individuals in different domains including composers, film directors, musicians, writers, painters, psychologists, scientists and spiritual leaders.

Audience

The encyclopedia is designed for use by students of creativity, as well as researchers, teachers, scientists, coaches and consultants, architects and designers, trainers, managers, actors, writers, directors, painters and other individuals in the creative arts, inventors, therapists and other professionals who utilize creativity in their work. Anyone who is interested in learning more about their own creativity and the creative process can benefit

from the articles presented here. Do not expect quick and easy self-help answers - individual creative growth requires work, time, serious thought and a commitment to deeper understanding of the process. And let's not forget the possibility of fun - creativity can help us experience the highest levels of involvement in work and play that ultimately leads to great joy. Readers are encouraged to follow their own interests and inclinations in exploring these volumes.

More than any other kind of book an encyclopedia is a collaborative effort. We thank our eminent panel of editorial advisors: Arthur Cropley, David Chan, Sandy Russ, Dean Keith Simonton, Ellen Winner and Jing Zhou. We also thank each of the distinguished contributors to the Encyclopedia. Finally, we appreciate the efforts of our editor, Nikki Levy, and our developmental editor Anna Gebicka. We hope this encyclopedia will not only inform but inspire readers to become more creative in their personal and professional lives.

HOW TO USE THE ENCYCLOPEDIA

The *Encyclopedia of Creativity* is intended for use by students, research professionals, and interested others. Articles have been chosen to reflect major disciplines in the study of creativity, common topics of research by professionals in this domain, and areas of public interest and concern. Each article serves as a comprehensive overview of a given area, providing both breadth of coverage for students and depth of coverage for research professionals. We have designed the encyclopedia with the following features for maximum accessibility for all readers.

Articles in the encyclopedia are arranged alphabetically by subject. Complete tables of contents appear in both volumes. The Index is located in Volume 2. Because the reader's topic of interest may be listed under a broader article title, we encourage use of the Index for access to a subject area, rather than use of the Table of Contents alone.

Each article contains an outline, a glossary, cross-references, a further reading list and a list of relevant websites. The outline allows a quick scan of the major areas discussed within each article. The glossary contains terms that may be unfamiliar to the reader, with each term defined *in the context of its use in that article*. Thus, a term may appear in the glossary for another article defined in a slightly different manner, or with a subtle nuance specific to that article. For clarity, we have allowed these differences to remain

so that terms are defined relative to the context of each article.

Each article has been cross-referenced to other related articles in the encyclopedia. Cross-references will always appear at the end of an entry. Where multiple cross-references apply to an article, the cross-references will be listed alphabetically. We encourage readers to use the cross-references to locate other encyclopedia articles that will provide more detailed information about a subject.

The further reading lists recent secondary sources to aid the reader in locating more detailed or technical information. Review articles and research articles that are considered of primary importance to the understanding of a given subject area are also listed. The further reading lists are not intended to provide a full reference listing of all the material covered in the context of a given article, but are provided as guides.

A select number of biographies have been included. These biographies discuss the lives of individuals famous for their creative endeavors. No living people have been included because we wanted creators whose work had stood the test of time. Although there are many individuals famous for their creative pursuits, you may not find coverage of your favorite here. Inclusion is not intended to be a judgment on the impact or value of these individuals or their creations.

Glossary

Brahma In Hinduism, the creator, the first member of the Trimurti, with Vishnu, the preserver and Shiva, the destroyer.

Commedia dell'arte Italian, meaning literally comedy of the artists (or guilds) is a form of improvised theatre encompassing a set group of characters played in masks that began in Italy in the sixteenth century and is still performed today.

Dissociation To break the association, to disconnect, to separate, to regard as separate in concept or nature. The essential feature of dissociation is a disruption in usually integrated functions of consciousness, memory, identity, or perception. The disturbance may be sudden or gradual, transient or chronic.

Kabuki Popular drama of Japan developed in the seventeenth century characterized by elaborate costuming with a stylized acting style comprised of rhythmic dialogue, music and dance; men playing both male and female roles.

Kathakali Highly stylized Indian dance-drama noted for codified body movements and gestures, involving elaborate

costume and make-up. Name derived from Malayalam words; katha (meaning story) and kali (meaning play or performance).

Method acting Derived from Stanislavski's system, a theory and technique of acting in which the actor identifies with the character and renders the part in a naturalistic, nondeclamatory and individualistic manner.

Noh theatre Traditional Japanese theatre and one of the oldest theatrical forms in the world. Name derived from Japanese meaning talent or skill. Performers are storytellers who rely less on plot than visual imagery.

Psychophysical Literally mind-body, pertaining to the idea that the mind and body experience events in parallel, and that the exploration of the body is a tool which at once creates and reveals deep emotional responses to express the human condition on a visceral level.

Sanskrit An indo-European, Indic language in use since c.1200 BC as the religious and literary language of India.

Introduction

Acting is an ancient art form that has existed since the beginning of recorded time. Although styles range from the ritualized Noh theatre of Japan, the poignant eloquence of Shakespeare's plays, the stark minimalism of Ingmar Bergman films, to the compelling energy of Bollywood movies, ultimately these theatrical forms share similar fundamental acting principles. The diversity of acting styles can be seen across time and across cultures with ancient acting, closer to what we understand as dance and mime, differing from what is presented today. Acting as a creative activity is one of several practices within the performing arts and all share three common phases of development; training/preparation, rehearsal/practice, and performance. Further, any study that investigates the performing arts must appreciate the reality that a performing artist is always embedded within a contextual setting and is engaged in one or more of the three phases of development. Acting remains a relational enterprise that involves moment-to-moment interactions with others while maintaining an ability to draw from personal past relational

experiences and imaginings with self, other, and/or the environment. It directly reveals the creative process to an audience; both performer and audience share in the immediate yet transitory nature of this art form.

Generally, empirical research on the performing arts lags behind that of the other artistic domains. Perhaps it is because acting is more process-oriented, even though a product is being performed. To help provide some coherence to this topic creativity research studies are frequently grouped into two general approaches, individualistic and contextualistic. Individualistic studies include research on the traits of actors (cognitive, personality, biological) while contextualistic studies examine the socio-cultural dynamics operating within creative ensembles and between actors and their audience. Fundamentally, an understanding of acting requires an integration of both.

Etymological definitions shed light on the universal concepts inherent in acting. The Webster's Encyclopedic Unabridged Dictionary (1996) described acting as "serving as something temporary; the art, profession or activity of those who perform in stage plays, motion pictures, etc." (p. 19). The word actor ('person who acts') appeared at the same time as the word act

(1350 – 1400). Another common term that was used in place of actor is player (AD 382), a term that described “a person or thing that plays; a person who plays parts on stage” (p. 1485). In fact, the terms playwright and playwriting are drawn from this word. Play (AD 1377) means “a dramatic composition that involves action, activity or drama; to act the part of a person or character in a dramatic performance” (p. 1439). Play, player, and playwright can be found in many of Shakespeare’s dramas and to this day we commonly use these and other terms such as playbill, playgoer, and playback.

Along with examining the process of doing or performing actions while imitating a character, the enterprise of acting also stimulates and engages the creative imagination of the actor and the spectator. Creativity is regarded as “the process in which original or meaningful new ideas, forms, interpretations or methods transcend traditional ideas, rules, patterns or relationships” (Webster, p. 472). Creativity is a relatively new term used to describe human endeavors, since this term was originally only reserved for the actions of gods; however, an older term, imagination, did describe human creative actions. The word and concept of inspiration served to bridge the behaviors of gods and humans. According to Plato in c. 388 BCE, the gods literally inspired or breathed their spirit into the imagination of the artists, hence it was understood that artists, guided by divine beings, became the messengers or actors of the gods; they were inspired by god to communicate to mankind through divine or supernatural influence. Lastly, the Ancient Greek words *poesis*, *physis*, and *techne* all remain part of fundamental acting practices of today. *Poesis* (poetry) is an action that springs from *physis* (spirit), considered our dynamic life force. These concepts, *physis* and *poesis*, are the inherent power that is felt when a great actor has stage presence or star quality and when a play inspires and transforms us. The third term, *techne*, captures the technical aspects of how an actor portrays a character and tells a story. From these terms we can conclude that acting is a creative process of actions that reveal characters and situations while engaging the imagination of the performers and their audience. It is a dynamic relational enterprise that can inform, stimulate, and inspire.

In this entry a brief outline of the major historical developments of world theatre, the acting training practices of today, and some recent research findings on acting and actors are discussed. Regardless of the medium (stage, film, radio, television, or the internet), the general practice of acting has remained timeless. When examining the historical evolution of acting, both in the East and West, what is fascinating and humbling is that the essential principles of acting tend to persist. The writings of such giants as Aristotle and Shakespeare describe what we continue to seek. Ultimately, according to Tadashi Suzuki (1986), acting demands “the actors involve their whole selves, their living bodies, in a collective performance” (p. 83).

Origins of Acting

Historians and anthropologists have assumed that theatre evolved from (1) ritual, (2) storytelling, (3) man’s innate behavior to imitate as a way of learning, (4) man’s natural

ability to play, and/or (5) engage in fantasy to reduce anxiety. Ritual enactments of myths that recount sacred history are considered the most salient origins for theatre and acting. In essence myths were regarded as reality and truth; they were attempts to reestablish the sacred through the performance of actions originally done by the gods. It is believed that rituals were healing attempts to control that which was frightening and unknown. Dance, music, masks, costumes, chanting, and narration performed on sacred grounds became the basis for ceremonial theatrical performances. The sacred ground for ritual gatherings became an acting area and the priests ensured that these rituals were performed correctly. They were the ones who impersonated men, animals or supernatural beings, sang and wore costumes, and masks. Theatre emerged from these dramatic rituals, especially when secular stories began to take the place of religious practices.

Second, many myths became the inspirational sources for stories and storytelling in which a narrator would impersonate the action and dialogue of other figures. In this form of mythic storytelling, the integration of dance, gymnastics, and rhythmic chants facilitated the portrayal of animal movements and sounds. The third possible origin of acting is revealed in the writings of Aristotle (335 BCE) who viewed humans as instinctively imitative; both enjoying imitating others and watching imitations performed by others. Aristotle believed that humans desired to know how other’s felt and why others acted as they did. He believed that imitation was man’s chief method of learning about his world. The fourth and fifth theories posited are that mankind has an innate ability for fantasy and pretend play and that these capacities may be used to decrease anxiety while preparing for new experiences. These last two theories are clearly manifested and continue to be practiced within community group theatre projects and group psychodramas. They offer a direct way of engaging the individual to tell personal stories with the goal of healing the individual and the community at large. These five theories assume that society recognized and valued the performance of myth and ritual, storytelling, imitation, and pretend play.

Origins of Acting: The East

Our knowledge about the origins of Eastern theatre and acting begins to take shape about 4000 BCE when Egypt and the Near East entered an advanced stage. Egyptian hieroglyphics supply the first tangible evidence of drama enacted by priests. In the Far East, according to Hindu legend, Brahma taught the art of drama to the sage Bharata, author of *Natyastra* (The Science of Dramaturgy), written around 200 BCE. Since it gives details on acting, dance, costume, and makeup it is assumed that these acting elements had long been in existence. The early Sanskrit plays were organized around fundamental psychological moods or ‘*rasas*’ (nine *rasas* include erotic, comic, pathetic, furious, heroic, terrible, odious, marvelous, and peaceful). A Sanskrit play contained many *rasas* but all plays ended happily; the intention was to leave the spectator in a state of harmony. Violence and death were kept off stage, good and evil were clearly differentiated, and good was always triumphant. These plays were only performed on special occasions such as marriages, festivals, victories, or coronations.

Hindu theatre depended most upon the actor who in turn relied on four basic resources: (1) codified movement and gesture, (2) speech and song, (3) costume and makeup, and (4) psychological insight. Gestures were classified linking body parts to inner feelings while speech and music was regulated by intonation, pitch, and tempo. Costumes, props, and makeup were used as symbols and the overarching goal was to illustrate the Hindu search for peace of soul, rest after struggle, happiness after trials, and submission to fate. During the twelfth century Sanskrit theatre ended; however, dance survived and was integrated, in the seventeenth century, into the dance-drama, Kathakali. Like earlier Sanskrit drama, it was based on Hindu epics, with exaggerated style, musical support, and symbolic representations of good and evil, love and hate, and the passions of the gods and demons. Performances frequently lasted all night. Similar dance-dramas were performed in Southeast Asia and shadow plays performed with puppets dominated in Indonesia. In the eleventh century, actors began to replace the puppets and puppet-masters but the use of music and mimed actions continued.

In China the first known beginnings of acting originated around AD 714 when Emperor Ming Huang opened the first training program for performers of music and dance (Students of the Pear Garden). During the reign of Chen-tsung (998–1022) semi-dramatic tales of history were performed with dance and song. Plays of this period were long with complex plots spanning over 30 acts. Around 1736–1795, the northern and southern styles were now merged to form the Beijing Opera. Characteristic of this form of theatre is the use of narrative to impart details of plot followed by a dramatic stylized performance of the climactic moments of the play. The intention of Chinese theatre was to stimulate the imagination of the audience and not to give the illusion of reality. Though it was common to have musicians and property managers on the stage during the performance, the focal point for the audience was the actor, who generally performed highly stylized speech and movement sequences and wore symbolic makeup and costumes. Not until the early twentieth century did Western spoken drama begin to appear in China including the construction of proscenium theatres that supported these productions.

In Japan, the influence of Buddhism during the eighth century resulted in dance plays that were more ceremonial in form. These Bugaku dramas were handed down through generations of families who inherited the rights to perform them. During the tenth century, the more rural Sarugaku and Dengaku rituals incorporated song, dance, tumbling, and comic sketches which evolved by the fourteenth century into Noh theatre. Its staging reflected Zen Buddhist values of simplicity and minimalism. Today Noh drama continues to be highly stylized, uses elaborate ceremonial costumes and masks, and is performed only by males. Like the other Southeast Asian theater traditions, puppet performances incorporating musical accompaniment and a narrator remained popular in Japan. Later, Kabuki theatre, a cruder form of theatre inspired by Noh and puppet theatre, developed around 1600. With the fall of the shoguns, Kabuki became Japan's major dramatic form of theatre mingling comic and serious performances, along with dance and song. All traditional Japanese theatrical forms required long and careful study. Only during

the early twentieth century did Western theatre appear in Japan, including the adaptation of Stanislavski's System approach to acting.

The common denominator for all theatre in the East is that of a long training tradition essential to integrate the acting demands of codified movement, voice and characterization, expert application of makeup and costumes, and the mastery of skillful use of props and musical instruments. The performers' ability to contain and engage energy and spirit, whether during stillness or acrobatic feats, defines the nature of acting in the East. It is a tradition that honors practice and discipline.

Origins of Acting: The West

Western drama began in Greece at festivals honoring Dionysus. Dances, hymns, and dramas (comedies, tragedies, and satyrs) were presented at these festivals. The earliest records of dramatic contests date back to 534 BCE. One of the first known playwrights, Thespis, involved only one actor and a chorus, but what was remarkable about Thespis is that he was the first individual to break out from the chorus and assume the role of the character (in honor of his achievement performers are still referred to as Thespians). Thespis used masks to perform all the characters. When he left to change characters the chorus remained on stage and filled the intervals with singing and dancing, hence the chorus was regarded as the principal unifying force in early drama. Aeschylus introduced a second actor into the action in order to allow face-to-face conflict; as this practice increased the role of the chorus began to decrease. Euripides reduced the chorus to the point where they were almost insignificant and instigated a more intense focus on questions regarding social norms, psychological realism, and philosophy.

By the fifth century, Greek plays were produced by wealthy citizens, choregus, who financed the costumes, scenery, musicians, and prepared the chorus and actors for the productions. The playwright/dramatists applied to have their plays performed at the festivals, were responsible for writing the work, directing, and acting. They were paired with a choregus who would help produce the work and if the play won the contest, the playwright received money and honor. The city Dionysia, the location where all festivals were held, contained the Theatre of Dionysus (a raked hill area for the audience and a flat terrace structure at the foot of the hill designated as the performing space).

Roman theatre followed the traditions of Greek theatre but expanded the notion of spectacle. The growing immorality and decadence of later Roman theatre alienated the early Christian followers and so Medieval theatre rose as a reaction to the theatrical productions of the Roman Empire. Although actors at this time were denigrated by the Christian church, elaborate Passion (Mystery) plays emerged as a way to celebrate religious festivals outside of the church. The emergence of Renaissance theatre saw an increase of support by the courts and academies and the church became less involved in theatre. Renaissance productions followed the spectacle nature of the earlier Roman theatre. In an effort to amplify the spectacles, intermezzi were provided between the acts of the drama. These intermezzi always included dance and song and set the stage for the development of ballet and opera. Renaissance

theatre was presented in ornate indoor venues including the introduction of proscenium stages that facilitated the use of elaborate scenery.

The Italian Commedia dell'arte grew in tandem with the drama of the Renaissance court and academy. This form of theatre was not spectacle-based: rather it was actor-centered. Skills in improvisation, vocal range, and physical movement facilitated strong characterizations (Pantolone, Dottore, and Capitano). Similar to the practices of Eastern theatre traditions, these acting ensembles worked together and individual actors developed the same role over time. Influenced by the power of Commedia dell'arte ensembles, other European professional acting companies developed strong dramatic works written by such great playwrights as Marlow, Moliere, Tartuffe, Johnson, and Shakespeare. Instead of focusing on elaborate spectacle these acting ensembles focused on the words of the playwrights; once again Western theatre returned to the wisdom offered by the early Greek theatre practitioners.

As the eighteenth century arrived, acting companies came under the increasing control of businessmen. Now the actors and playwrights were the employees, rather than active participants in the management of the productions. Restoration drama, especially the comedy of manner genre, grew more sentimental and pantomime became a weaker version of commedia dell'arte. Opera started to separate from the dramatic presentations and was now performed independent of plays performed by actors. During the nineteenth century, along with the firm theatrical control of businessmen, Romantic drama and Melodrama held sway. Repertory companies increased during this period but so did the star system in acting. Celebrity artists such as Henry Irving, Edwin Booth, Elenora Duse, and Sarah Bernhardt travelled widely, drawing audiences from all walks of life. Theatres now specialized in particular forms of drama (pantomime, variety hall, opera, ballet, drama), and audiences were provided greater freedom to select productions that specifically interested them. Diversification and possibilities made available by new technology such as radio, cinema, television, and the new electronic mediums led to even more specialization.

The Director and Acting

Western theatre shifted from the earlier focus on the poet in the Elizabethan stage, to the actor in the eighteenth century, and finally to the 'metteur en scene' (master of the scene) who controlled the appearance of the stage in the nineteenth century. With growing value placed on appearance, actors changed their approach as well. The words of the playwright had less meaning and in its place virtuoso performances matched the elaborate sets and costumes of the day. At the pinnacle of nineteenth century theatre, the 'metteur en scene,' now known as the director, moved from the role of stage manager to the one who conceptualized the images that appeared on the stage. At the end of the nineteenth century a backlash against spectacle led to the introduction of realism. Andre Antoine was one of the first directors to create a repertory theatre company with the vision of integrating reality as the unifying force in dramatic works. Shortly

after, Stanislavski broke further from the ranks. As a director he explored all possibilities to achieve a realistic production. Ultimately, in order to get the emotional depth of a theatrical work he realized that he needed to train his actors. Due largely to his efforts, the focus on the actor and acting returned, and with it literary meaning was once again merged coherently with staging design.

Acting Theory

In *The Poetics*, Aristotle (c. 335 BCE/1958) clearly outlined the essential ingredients for dramatic performances and his ideas remain powerfully resonant in today's international acting traditions. He stated:

So all the arts . . . produce their imitations by means of rhythm, speech and melody, using them separately or together. . . . Since those who make imitations represent men in action, these men must be superior or inferior, either better than those we know in life or worse, or of the same kind . . . that is why their works are called dramas, because they represent men "doing". (pp. 3-6)

He grounded his theory of imitation in the natural activities of child's play and the pleasure and learning gained during this activity. He claimed that poets must employ insight and clarity to represent men in action and they must determine the positions and attitudes of the actors in the play who will imitate the characters. Aristotle believed that gifted poets expressed powerful emotions only when they felt them. And what differentiated gifted poets from the ungifted was the ability to remain balanced and not get lost in the characters they portrayed. He also offered a warning, that actors must not become more important than poets; it is the balance of all these elements that make theatre vibrant and meaningful.

In *Hamlet*, Shakespeare (1623) offered a similar perspective. Hamlet demanded that his players "Suit the action to the word, the word to the action, with this special observance, that you o'erstep not the modesty of nature . . . to hold, as 'twere, the mirror up to nature" (*Hamlet*, Act III, Sc. I, lines 18-21). Both Aristotle and Shakespeare insisted that acting was a fusion of word and action that was rooted in the truths of nature. Performers were charged with the responsibility to engage their entire *self* in the portrayal of another; they were to give life to the character and the action of the play. Today, Tadashi Suzuki, one of Japan's leading theatre-makers, echoes the thoughts of Aristotle and Shakespeare. In *The Way of Acting* (1986), he stated: "The art of stage performance cannot be judged by how closely the actors can imitate or recreate ordinary, everyday life on the stage. An actor uses his words and gestures to try and convince his audience of something profoundly true. It is this attempt that should be judged" (p. 5).

These major concepts confirm the universality of acting in which actions are performed in a contextual relational field between the performers, the audience, and the socio-cultural experiences that have shaped them. To perform something profoundly true, to hold the mirror up to nature, to retain critical balance and yet maintain an ability to be emotionally engaged requires training and practice, and then it must be performed with others in the immediacy of the present moment.

Major Acting Theories of Today

Stanislavski

Konstantin Stanislavski's System remained dynamic throughout his life due to social and political constraints and his own personal search for creative clarity. Living in Russia he experienced European and Asian artistic traditions and saw popular shifts in theatre from nineteenth century histrionics to the realism and modernism of the twentieth century. He strove to codify the experience of creativity on stage into a common system which he himself warned never to use as a philosophy but merely as a handbook to bring the actor closer to the nature of creativity. He experimented with symbolism, verse, opera, western behaviorist psychology, eastern ideas on the mind-body continuum (including yoga), and trends in criticism in art and literature. He became the first Western practitioner of the twentieth century to articulate actor training, calling it the grammar of acting.

The elements of his actor training (concentration, imagination, and communication) were regarded as skills that needed to be learned and controlled. Concentration demanded a sharpening of the senses of sight, hearing, touch, smell, taste, and affect. He achieved this through a series of exercises to recreate specific sense experiences drawn from memory and imagination. Stanislavski believed it was important to energize imagination through exercises such as:

- visualization (i.e., imagine that you are a tree and see what type of tree you are, how thick is your bark, etc., a process that led to progressively more specific details evoked in the visualization);
- use of random words to spark the imagination and then connect them into a narrative (improvisational practices commonly used today in improvisational theatres);
- take familiar events and fantasize different outcomes;
- take objects and explore the 'what if' of these objects (i.e., what if this glass of water were poisoned and it is your last drink).

In his explorations on communication, regarded as the interaction between scene partners and between actors and their audience, he added the less tangible experience of subtext (the unspoken narrative operating concurrently with spoken dialogue).

Stanislavski's most pervasive belief, a holistic view that the mind and body represented a psychophysical continuum, became the foundation for his training philosophy and the conditions for performance. Both mind and body had to be in a state of relaxation in order to withstand the demands of the creative process. As a result, he suggested that actors practice the poses and breathing of yoga to build habits of relaxation, and that they remain essentially dynamic and improvisational during performance. He believed that the actors could then experience the sensation of existing fully within the immediate moment, a sensation which he referred to as 'I am,' which is commonly described today by actors as being in the moment. He advocated a recursive practice of exploring a sense of self followed by exercises in imagination, concentration, and communication that reinforced the actor's sense of self. This became the process in which an actor prepares.

According to Stanislavski, the second part of actor preparation was the construction of a role. It involved the above elements but they were now examined from the perspective of the script. There were a variety of ways to examine a role, such as scoring actions from intellectual, imaginative, and affective explorations, or relying on physicalization and active analysis. Stanislavski described affective cognition as an analysis of all the details of the play, including research into the history and social world of the play, and visualization of the character going through a typical day. Identifying the actions was considered the heart of Stanislavski's System and began with breaking the play down into segments (units of action, bits, or beats). Each segment described the circumstance of the character's situation and was identified by specific active verbs to express the segment of action. When taken together these scores of action told the story of the play and posed a series of problems, which the character must overcome. It was through the attempt to resolve these problems that conflict arose between characters; these became the source of dramatic tension. During the performance the actor placed full attention and concentration on carrying out these actions with the character's emotions arising naturally as a result. Stanislavski stated "If our preparatory work is right, the results will take care of themselves." In his system the actor must focus on the actions and not the results.

Stanislavski's rehearsal methods remained dynamic; however, he never lost sight of how best to support the actor's connection to the role being prepared. What remained consistent was his belief in the three basic drivers behind creativity: (1) 'mind' (for analysis and understanding), (2) 'will' (for control and physical preparedness), and (3) 'feeling' (fostering passionate and zestful relationships with the characters being created). Stanislavski's System continues to inform acting practices around the world. He paved the way for actors to perform what Hamlet requested, "Suit the action to the word, the word to the action."

Those that Followed Stanislavski: An Individualistic Approach to Acting

Although most twentieth century acting training methods draw from the influence of Stanislavski, many practitioners have added their own personal perspective. These perspectives range from extreme oppositional stances to more nuanced departures. The approaches can be understood from multiple points of view but for brevity's sake, we will categorize the theorists within two general groupings, individualistic and contextualistic.

The individualistic group tended to focus on the training of the actor, although these practitioners were equally aware that a relational context was always operational. For example, Vsevolod Meyerhold sought to train the brains and bodies of actors to be more theatrical. He devised biomechanical training principles that amplified gestural expressivity. Jerzy Grotowski developed a theatrical style that amplified the archetypal truths of the character. He integrated a psychophysical training that included extensive physical training.

Michael Chekhov developed a training that incorporated psychological gestures, imagination, and concentration practices with the goal of creating dramatic atmospheres or moods

for the characters. Chekhov focused on a clear sense of form shaped by the rhythmic flow of energy and the dramatic climaxes and accents inherent within each dramatic work. In an attempt to intensify the experience for his actors and his audience, repetition was practiced both in the training of his actors and in the performance of his productions.

Uta Hagen claimed that the actor is the closest figure to the audience; both are present while the art is being created. She differentiated external representational acting (actor to imitate or illustrate the character's behavior) from internal presentational acting (actor attempts to reveal human behavior through a use of self). Hagen's overarching belief was that through an understanding of self an understanding of the character being portrayed would emerge.

Lee Strasberg, Stella Adler, and Sanford Meisner were all Stanislavski trained; however, they went on to shape their own particular brand of acting training. Strasberg focused more on the psychological realism of the character, Adler on the sociological perspective, and Meisner on behavior. Although they had their own particular focus they were all considered founders of Method acting. This approach insisted on the actor justifying every word, action, and relationship. Method acting attended to the careful analysis of objectives, actions, and intentions. Moment-to-moment impulses were followed as a means of giving life to the actions and active listening supported the inter-relational actions within and between actors. This form of training enhanced the actor's unique personality since each actor was asked to draw from personal emotional, psychological, and imaginative realities that were to be revealed directly to an audience. As a result, each character resembled the actor and so the actor was frequently cast based on shared attributes with the character to be played. Method acting is perhaps the most widely used technique for film work. The camera captures the most intimate emotional shifts of the actor. The Method has spawned some of the great actors of the twentieth century: Brando, Dean, Hoffman, Deniro, Pacino, to name but a few.

Those that Followed Stanislavski: A Contextualistic Approach to Acting

Bertolt Brecht was a powerful force in modern theatre. He challenged theatrical norms by blending and contrasting comedy, high drama, and song together in a single play. He drew characters from a socio-political perspective and his actors portrayed these characters from this perspective. This required strong physical, emotional, and vocal training. He called this character work *gest* or *gestus* and contended that the power of *gestus* enhanced audience understanding of the play and its larger socio-political implications. He referred to this work as theatre of alienation, a process in which the audience was emotionally engaged yet prevented from personally identifying with the characters. Brecht, as playwright and director, wanted his performers and audience to question and explore.

Peter Brook was a strong proponent of ensemble productions and communal explorations. He claimed that truth in the theatre is always dynamic and encouraged his performers to actively seek the impulse inherent within the word, a process that he believed would join the truth of the performer and the playwright.

Those that Followed Stanislavski: East–West Integration

Eugenio Barba fundamentally rejected Stanislavski's System of acting training and focused his attention on the symbolic conventions of Eastern theatre. He examined the use of energy as a way to generate power and believed that mastery and total presence within a performer was achieved through an integrated mind-body-energy process. Focus on the spine, balance, weight, space-time relationship, and core expressions facilitated this integration and, after a long training process, his ensemble was able to perform productions that incorporated a fusion of Eastern and Western cultural traditions.

Tadashi Suzuki is a master at integrating the ancient traditions of Japanese theatre with modern Western practices. Following Eastern acting practices, Suzuki continues to train his performers with a focus on the physical expression of human existence. He advocates practices for strengthening the use of footwork and vocal range and insists on balance, containment, and transformation of yin (soft) and yang (strong) energy. He maintains strong communal practices in which his actors live and work together and are influenced by and participate in their surrounding community. Ann Bogart, one of America's most respected experimental theatre-makers, was deeply influenced by the work of Suzuki. She actively explores these same polarities of energy as she examines themes of violence, terror, disorientation, and paradox. Her training method, Viewpoints, is a series of exercises and staging devices that probe these complex themes. Like many, she incorporates the psychophysical actions of her performers as she examines the social structures around her.

Empirical Research Studies and Acting

Individualistic Research Studies

Individualistic research methods have provided greater understanding about the psychological aspects of actors. For example, Kogan claimed that performing artists were generally regarded as interpretive artists rather than creators; however, many interpretive artists described their experiences as highly creative. His research findings revealed performing artists as possessing innate talent and training, strong skills for memory retention, physical dexterity, and emotional self-expression. Further, he claimed that actors had stable internal attributions (they believed that they had control over the outcome of their performance) and external attributions for failure (not getting hired from an audition because they were not a good fit for the role). As a result Kogan's research suggested that actors did not have a depression profile even though they experienced great stress while maintaining a career as an actor and that working creatively in the public eye was considered a source of stress as well as inspiration. Daniel Nettle found similar psychological profiles for actors. He examined a group of professional actors who demonstrated higher levels of extroversion, openness to experience, agreeableness, and empathy as compared to a general population sample. Goldstein, Winner, and Wu found that actors actually had better theory of mind abilities but did not demonstrate higher levels of empathy. Gluck, Ernst, and Unger added to the psychological profile of actors.

They found that actors believed that imaginative assertiveness, cultural competence, intrinsic motivation, and having many ideas enhanced creativity.

Individualistic studies focusing on affective qualities have added further to our understanding about actors and performing artists. Feist found that actors were more emotional and sensitive than nonartists. This result was shared by Fuchs, Kumar, and Porter who found that performers had an ability to feel and express emotions honestly, as well as in unique ways that were effective in meeting the demands of both intra- and interpersonal situations. They suggested that performers had emotional creativity. A study conducted by Thomson, Keehn, and Gumpel found that performing artists were emotionally less variable compared to a control group which suggested that these artists possessed more emotional regulation. However, anger, sadness, and spirituality, along with higher scores on fantasy proneness and traumatic experiences, predicted elevated levels of dissociation in this population. Further, interpretive artists (actors, dancers, musicians, opera singers, directors) as compared to generators (writers, choreographers, composers, designers) had elevated levels of dissociation. This research team posited that interpreters may be able to submerge themselves within the role of a character, in part because of an increased ability to employ nonpathological dissociation, in particular, the ability to engage in heightened states of absorption that cause diffuse self-states and intense sensory-emotional imaginative experiences. Other research groups found a similar pattern of elevated dissociation in writers who, during the creation of their characters, experienced them as though they were independent agents. Dijkstra, Kashcak and van der Zwan demonstrated that assuming specific physical postures enhanced memory retrieval and evoked specific emotional states. Interestingly, this empirical finding supports the intuited psychophysical traditions of the East and West that were practiced from the earliest days of acting.

A slightly different line of investigative research focuses on boundary blurring versus boundary stability within the actor's personality, especially during the performance and the aftermath of portraying a character. According to Burgoyne, Poulin, and Rearden different acting techniques may lead to more boundary blurring with the potential increase of psychological distress if the actor is not able to regulate and discern self-other contextual shifts. They differentiate acting that is rooted in inside-out approaches (advocated by Stanislavski and his followers) from acting that is outside-in (more distancing practices to keep the character in the third person). The inside-out approach requires actors to personally connect emotionally to their characters; hence, a blurring of role/self may provoke a loss of control on stage or cause increased emotional distress after the performance. Although the inside-out approach may lend a performance more immediacy and potency, the actor is at risk for increased psychological distress. They suggest that educators, directors, and the actors themselves need to be aware of potential personality shifts and the adoption of the character's personality. This caution was substantiated by the work of Hannah, Domino, Hanson, and Hannah who found that actor's self-perceived personality profile did become similar to the character during the rehearsal and production period.

Based on this small sample of individualistic research studies, we can posit that:

- actors value creativity and imagination;
- have a strong sense of well-being, self-regulation, and intrinsic motivation;
- possess innate talent (physical dexterity, memory retention) and a capacity for training;
- endorse higher levels of nonpathological dissociation;
- have a stressful career;
- are more emotionally sensitive;
- possess greater theory of mind abilities as compared to empathic abilities;
- exhibit more extroversion, openness to experience, and agreeableness;
- may be vulnerable to boundary blurring.

Contextualistic Research Studies

Contextualistic researchers such as Sawyer claimed that any investigation into acting should include a study of group interactions (between performers, production teams, and the audience). Peak experiences for performers and audience became magical moments when reciprocal emotional contagion occurred. They suggested that actors have greater facility to relive emotional states and this freedom helped audiences experience their own emotional states. Kogan's research, later supported by Goldstein, suggested that performing artists are usually drawn to this profession early in life when they also have some family support. Other research teams have replicated this finding, claiming that creative achievement was facilitated by a confluence of varying intrapersonal and interpersonal factors (cognitive abilities, personality traits, intrinsic motivation, familial resources, societal factors, and cultural considerations). This socio-cultural contextual line of research reinforced the concept that actors are embedded within a relational field during their creative work and that early experiences supported their career choice and their ability to succeed in it.

Concluding Remarks

Although Eastern and Western traditions present stylistic and aesthetic differences, the training of the actor and the concepts of acting are more similar than contradictory. What crosses time, culture, and medium is the need to train the actor. Gestures and movement, speech and song, psychological insight, storytelling, and creative imagination are all skills that require long training to master and ongoing exploration to perform. Recent empirical research studies on acting demonstrated that actors are not depressed despite the reality that they maintain stressful careers. They were shown to be self-regulated even though they were emotionally more sensitive and engaged in more dissociative experiences. Perhaps their psychological stability was supported by the socio-cultural groups in which they participated and the early support they received for their interest and training in their career. These studies reiterated Aristotle's theories; acting arises from the innate human instinct to play and imitate in an effort to increase understanding and reduce anxiety.

Acting is a process even when it delivers a product. For the actor and the audience the process of acting is revealed in the ephemeral immediacy of the shared moment. Whether the moment is a failure or a success, performers and audience experience it. It is ultimately a poetic process of doing actions during the imaginative engagement of imitating or representing characters and situations. The magic inherent in acting is experiencing the spirit of the performers who have sought to master the integration of mind-body-energy-spirit. Words found across all cultures (such as prana, chi, soul, yugen) name this integrative and enlivened state, a state inherent in all imaginative works and in the great acting practices found across all cultures.

Acting traditions teach artists to find a balance between technique (techne) and content (story/poetics). The moment Thespis stepped out of the chorus and stated "I am Dionysius" was a revolutionary moment. He had the courage to embody another. Acting is dynamic and alive and it invites performer and spectator to engage. It reunites us to our humanity.

This article is a revision of the previous edition article by LeoNora M Cohen and Don Ambrose, volume 1, pp. 9–23, © 1999, Elsevier Inc.

Glossary

Accommodation The act of modifying or adjusting the knowing structures in order to deal with discrepancies or conflicts to them.

Adaptation The act or state of adjusting to fit environmental conditions through conformity, agreement, or compliance; to acclimatize or apply experience to the use or selection of an environment to personal advantage; to modify or transform the environment to suit the individual.

Adaptiveness One's ability to adjust to conditions or environments, such as requirements of a given culture or context, or to change as needed to fit such conditions.

Assimilation The act of bringing in elements or aspects to the systems or knowing structures that conflict with those structures.

Continuum of adaptive creative behaviors A continuum of seven levels of creative behaviors that explains the shift in adaptation from individual-to-world to world-to-individual.

Culture The sum of ways of living, behaviors, and beliefs characteristic of a particular social or ethnic group as well as

the political, economic, and technological forces that impact that group in a particular place and time, usually transmitted from generation to generation.

Equilibration The act of restoring a balance when conflicts to the knowledge systems occur through the processes of assimilation and accommodation; the linking mechanism between adaptation and the mental organization of the individual; the mechanism by which the individual moves from one developmental stage to the next.

Mature creativity (Capital C Creativity, according to Mihaly Csikszentmihalyi). The products or performances of individuals who have mastered a field or fields at very high levels, normally associated with adulthood; creativity by extension or transformation of a field.

Mundane creativity (Creativity in the small, 'Little c,' or personal creativity). Creativity that is new to the individual or perhaps to peers, but does not result in products or performances that are rare or of value to the world.

Structure The mental organization(s) of the individual based on what has been previously assimilated and accommodated.

Depending on the situation, adaptation can hinder or support creativity. In some cases, adaptation means tightly conforming to a confining environment that stifles creativity. In other cases, it means creatively adjusting to the subtle nuances of a changing environment. Adaptation also occurs when individuals force the environment to change in response to their needs or efforts. Adaptation may even mean that individuals move out of one environment into another better suited to their abilities or preferences. In most cases, creative adaptation in our highly complex world involves most or all of these mutually shaping influences between person and environment.

The dynamic interplay between person and environment is one of the most important issues in analyses of creativity. Certainly, culture, the combination of tradition, values, customs, rules, behaviors, and beliefs, as well as the political, economic, and technological forces that impact a given group in a particular time and place need to be taken into account in adaptation and creativity. The focus of this article is on who does the adapting. On one hand, some definitions and theories related to creativity and adaptation focus on conforming to or fitting in to an environmental situation by the individual. Those who do not 'fit' into prevailing values and mores are considered weird, maladaptive, or even dangerous. For example, Elisabeth Rudowicz noted that Eastern or traditional cultures would consider creative products or ideas that counter values and child rearing practices of a given culture as unacceptable or dangerous. However, when adaptation is viewed as

modifying or transforming the environment, particularly when the created products or ideas are valued by a culture, the creator is considered the epitome of human development and health.

This article explores a wide range of issues and concepts relevant to creative adaptation. These include (a) definitions and theoretical perspectives on adaptation, adaptiveness, and culture, (b) research on adaptation and creativity, (c) facilitation of adaptation for creative individuals, and (d) a developmental continuum of creative behaviors in which there is a shift from individual adaptation to the environment to adaptation by the world to the individual. This developmental continuum accounts for creativity in both young children and eminent adults. Variables that influence development along the continuum include purpose, novelty, value, speed, and structure.

Definitions of Adaptation and Adaptiveness

The term 'adaptation' is derived from the Latin, meaning 'to fit.' The dictionary definitions for adapt are "the act of adjusting to environmental conditions"; or, "the modification of an organism or its parts that makes it more fit for existence under its environmental conditions." Adaptiveness in this article is one's ability to adjust to conditions or environments, such as requirements of a given culture or context, or to change as needed to fit such conditions. Mark Runco noted that

adaptation (and adaptiveness) rests on personal reactions, perhaps influenced by social relationships and socioeconomic influences, as well as dealing with tension, challenge, and adversity in life. While one person may see a problem or gap, another does not; or one person may be stressed and overwhelmed by adversity, another may find that same set of events challenging and exciting. In her longitudinal study of 30 000 disadvantaged young people from two distinct cohorts, Ingrid Schoon found that the particularities of the time period and historical context further shape adaptiveness, resilience to adversity, academic attainment, and creativity.

There are three distinct shades of meaning for adaptation. As described in the dictionary definition, the first and most common is adaptation as fitting in – conformity, agreement, compliance, or yielding to environment or situation. Essentially, this is modification of self to fit environment. For example, a new employee quickly adapts by talking about sports or pop music to ‘fit in.’ In this view of adaptation, individuals who do not conform to prevailing values, mores, and practices of a given culture or context often are considered maladaptive outsiders or even lunatics. Early definitions of creativity, in fact, focused on the pathology of creators. Such definitions portrayed creators as neurotic or mentally ill, partly because they were unable or unwilling to adapt to the styles and customs of the times, helping to explain crazy artist or mad scientist stereotypes. But groundbreaking, paradigm-shifting creators do not make their impact by conforming to the prevailing belief systems of their eras. On a smaller scale, a creative young person who does not conform to the prevailing fashions worn at school, or who does not hang out with the ‘in’ students is likewise often ostracized. This failure to adapt may or may not be a sign of mental instability. When a little child says, “Look how my shadow is glued to me!” this unusual and delightful use of words is hardly a sign of neurosis. Instead, it is a creative-adaptive attempt to understand the world. In like manner, the student who bucks the system when faced with another boring work sheet may be demonstrating a healthy sense of self.

A second definition of adaptation emphasizes the role of experience in successful orientation to an environment or situation. Adapting to the heat and humidity by resting in the afternoon when living in a tropical country is an example. One type of intelligence involves rapid ‘reading’ of an environment and selection of responses that provide the greatest benefit to the individual. For example, a politician who sizes up a crowd and delivers a speech tailored to that audience could be considered contextually creative because he or she successfully uses experience to adapt to a given situation.

Experience also can help individuals select environments best suited to their full development, or even reject a detrimental environment. Examples of this kind of adaptation include moving to a setting that is aesthetically invigorating, enrolling in a school that offers a program of deep interest, or leaving a job when it becomes debilitating or toxic. Such selection of an environment based on experience might prevent maladaptive situations where individuals do not feel they belong. It also may prevent high-potential people from feeling inferior and developing a poor sense of self based on an environmental mismatch.

A third definition of adaptation suggests something different; that is, the individual acts on the environment to modify,

change, translate, or transform it. For example, some creative employees make work environments more fulfilling and challenging by initiating innovative and interesting projects in otherwise barren, stifling offices. On a larger scale, some highly creative people modify their environments by developing profound ideas or products that affect many people for long time periods. For example, Thomas Edison’s inventions and Albert Einstein’s theories made high-impact, long-lasting transformations that continue to influence the present.

In considering the dynamics of creative adaptation and adaptiveness, the issue is directionality. Eminent adults must adapt to their environments, but they also encourage the world in which they function to adapt to their ideas and products. In contrast, children and adult novices concentrate on adapting to their environments, and exert little influence on those environments. Both of these forms of adaptation involve creative thought and action, but what is creativity?

Definitions of Creativity

The most common definition of creativity involves the production of something appropriate yet new or rare that is valued and accepted in the world. However, this definition applies only to creativity in eminent adults because children are unlikely to produce something truly new or valued by people other than their families or peers. Hence, this definition is not very helpful to those concerned with creativity in the classroom, nor does it apply to mundane creativity or personal creativity ‘creativity in the small’ – ‘Little c creativity,’ or even, as Ronald Beghetto and James Kaufman suggested, ‘mini-c creativity’ – the less than earth-shaking variety of creative products or ideas made by children and adults such as making an unusual meal, lovely garden, or delightful finger painting.

Creativity involves a paradox: an original, novel idea or product as well as its acceptability, appropriateness, and usefulness to a given group or society. Creative adaptiveness is the ability to adjust flexibly to conditions or environments in developing new ideas or products while adhering to what is approved of or permitted in a given cultural context. It requires, according to Elisabeth Rudowicz, commitment to the sociocultural system, not exceeding boundaries to be too foreign or perceived as dangerous to that context, more typically involving modification or improvements, rather than new inventions.

J. P. Guilford’s conception of divergent thinking is probably the second most common definition of creativity. Divergent thinking involves production of ideas from given information, with an emphasis on variety and quantity of output involving fluency, flexibility, originality, and elaboration. “How many uses can you think of for a cup?” is a typical classroom problem based on this definition. It appears to apply to both childhood and adulthood, but does not likely span the gap between children’s creativity and mature, eminent creativity and it relates more to problem solving.

Definitions of adaptation are influenced by differences between problem solving, its application as entrepreneurship in business, and creativity. Both creativity and problem solving share a common starting point – incongruity in a problem. Both also require knowledge, motivation, repetition, and

discovery of unique combinations. In addition, there are phases or stages in the problem-solving process. In entrepreneurship, an application of problem solving to business, Codrin Kruijne suggests three phases which continuously recycle:

1. perceiving the current state of the business in historical perspective and why things happen as they do, which requires monitoring of self and performance in the environment;
2. selecting among possible actions, which pressure the entrepreneur due to limited resources;
3. acting and monitoring to see if the action improved the product or situation, inspiring others to work towards the adaptation.

But problem solving (and entrepreneurship) and mature creativity are different in duration and effect, both externally and internally. Problem solving is generally a short-term process while creativity at higher levels is life-long. Creativity at high levels also focuses on a larger unit of analysis, more on a totality rather than a specific answer, and it usually involves a greater impact on the world. Additionally, in problem solving the problems are typically externally set, with the focus more on resolution. By contrast, mature creativity involves problem finding wherein both problems and innovative solutions are generated internally and intrinsically, although there certainly are both external stimuli and parameters.

Mature creativity involves a discontinuity with what was before, while problem solutions can be explained by more continuous, straightforward processes. For example, solving the problem of how to get kids to use more toothpaste might involve researching children's flavor preferences and making cherry-flavored toothpaste. Creativity, on the other hand, involves a shift in context, which allows the creator to see the world in a new way. In this process, the connections between the new and the old perspectives on the situation are not directly discernible. For example, in coming to understand the inner world of individuals, Freud created new perspectives with his concepts of id, ego, and superego. These new concepts produced a discontinuity with the knowledge that had prevailed previously in the field. Such discontinuities are consistent with Howard Gruber's conclusion that mature creativity involves the construction of a point of view while problem solving does not. Gruber came to this conclusion during his analyses of the works of highly creative individuals, Charles Darwin and Jean Piaget.

Mature creativity, then, involves both external transformation of a field and internal transformation of self. Adaptation is evident in both aspects. External transformation involves sensitivity to a context as well as awareness of the limitations of a field and the desire to work hard to transform it. This is primarily adaptation by external transformation although there are certainly internal aspects, such as the zeal to put forth effort. Internal transformation involves sensitivity to one's self and the openness and willingness to modify one's present ways of thinking in order to construct a unique point of view. Thus, mature creators adapt in both ways, modifying the environment to fit their schemes and theories and modifying themselves to be able to accommodate to the environment. This is not a meek or passive attempt to fit in. Rather, according to Howard Gruber, it involves the active construction of a way

of looking at the world. It is not always conscious, but it is dynamic and effortful. In both external and internal transformation, adapting means being tolerant of uncertainty or ambiguity outside and in, being willing to not have answers, to be wrong, to try alternatives.

Theoretical Perspectives Related to Adaptation

Returning to the three definitions of adaptation, early definitions of creativity focused largely on the fitting of individual to the environment, sometimes by equating mental instability with creativity. For example, Freud believed that creativity arises from attempts to sublimate libidinal or sexual impulses into more socially acceptable forms; in short, adapting to the values or mores of the times. For him, creativity and mental illness have identical origins, both arising from conflict within the unconscious. According to Freud, creative individuals blend productive abilities with neurotic tendencies.

The first theorist who suggested a direct relationship between creativity and adaptation, however, was Freud's disciple, Otto Rank. Rank broke with his mentor over the issue of sexual sublimation as the motivating force in behavior. Instead, Rank believed that motivation came from the dynamic tension between the wish to depend on and unite with others, and the wish to separate from others in order to assert one's individuality through the will. For Rank, the will is a life-shaping force that includes a sense of self and a sense of what the individual wishes to accomplish. As a positive force, it is the urge to create; as a negative force, it manifests itself in repression and control. If parents have a healthy regard for their children as individuals and grant them autonomy and the chance to assert their own will, children move toward a secure sense of self. This enables a child to establish independent individuality through force of will without feeling rejection from the parents. When the child is not accepted as separate and different, the will becomes a source of guilt instead of ego strength. Rank's definitions of three distinct personality types: adaptive, conflicted, and creative or artistic, clearly portray adaptation as fitting in to an environment and as counter to creativity.

Rank called the 'adapted type' the creativity-inhibiting personality of the 'average man.' Very early on, the child identifies with and adapts to the will of the parents and later, to the will of society, in order to avoid the pain of guilt. This form of adaptation produces harmony and reduces the potential for conflict, but it also works against creativity. Rank's 'conflicted type' is characterized by divisions in the personality. These divisions involve moral struggles against the compulsion of the outer world as well as inner conflicts between the will of the child and the will of the parent. The individual attempts to form personal goals, ideals, and standards, rather than those sanctioned by society, but remains conflicted, guilty, and unable to move to the third level of creativity and productivity. For Rank, the third and ideal personality type is the creator or artist. This is the ideally functioning person who has accepted and integrated two conflicting fears: the fear of being a separate individual and the fear of union and dependency. Acceptance and integration of these fears produces ideal mental development and healthy behavior wherein the creative impulse

comes from the desire for immortality. In Rank's theory, adaptation is antithetical to creativity because it exclusively involves fitting into the environment. Creativity requires the individual to resist adaptation through the will to create.

Psychologist Jean Piaget generated a constructivist-developmental theory that portrays intelligence as adaptation. His theory explains how individuals adapt by modifying their knowledge structures to fit the environment. Piaget also linked intelligence to creativity, calling early childhood the most creative period in life because young children construct their understandings of the world. According to Piaget, intelligence develops through the child's actions in and on the social and physical environment. Using the mechanism of reflective abstraction, the child projects new concepts to a higher plane of understanding and reorganizes them at that higher level, thereby creating ever-more-complex relationships among actions, objects, ideas, and social experiences. Piaget believed that this mechanism is the same in both child and eminent creator.

For Piaget, individuals adapt through the process of equilibration, actively assimilating concepts that relate to their idiosyncratic knowledge structures and accommodating new concepts that do not fit current structures by modifying those structures, thereby evolving through distinct levels or stages of organization. Through these processes, growth in understanding arises from environmental or internal stimuli that cause gaps, conflicts, or disturbances in current mental structures. These discrepancies provide the impetus for reorganization of the mental structures. Thus, individuals adapt to the environment by modifying themselves. Each equilibration leads toward higher and broader levels of understanding, hence stronger adaptation.

In Piaget's theory, the concept of discontinuity provides the first glimmerings of adaptation of environment to individual. Discontinuity occurs because the construction of relationships is not inherent in the elements themselves, but is brought about through mental action. It is the individual's own construction and imposition of orderly rules and patterns on environmental objects or events that make this adaptation of the environment to the individual. This is the case even if the same rule has been constructed for centuries by other learners. For example, the little boy who is arranging sticks from smallest to largest and generates the idea of putting all the ends against a baseline has constructed the rule for seriation discovered by every child who does so. This child has imposed order on the environment that is not inherent in the sticks themselves (a discontinuity) as he modifies his structures to create the rule for seriating. As in this example, Brian Sutton-Smith noted that play is essential to adaptive capacities, allowing for variability and experimentation not always available in everyday life wherein unexpected things happen when there are no rules inherent in the play.

Except for statements about early childhood, Piaget said little about creativity, with the exception of his three rules for being creative:

1. after becoming knowledgeable in a field, read widely around it, in order to cross-fertilize that field with new ideas;
2. have an adversary in mind, something against which you react;

3. believe in yourself and distrust influences from the outside.

From these rules, it appears that Piaget was going beyond merely adapting to the world to protecting the self from the world and even to shaping it.

Developmental psychologist David Feldman proposed another perspective on adaptation. Feldman claimed that universal cognitive development moves the individual toward competence with the general adaptive abilities that are needed for getting along in the world. From this viewpoint, adapting is finding a satisfying, useful way to live. This is similar to Piaget's notion of intelligence as adaptation. But Feldman also described nonuniversal development, which takes place in creative individuals and child prodigies. Not everyone attains this type of development. It requires specific instruction and the sufficient development within a field in order to reach very high levels. This domain-specific development can be thought of as talent that enables the individual to excel if the right niche is found.

In his seminal book, *Beyond Universals in Cognitive Development*, Feldman described a Universal-Unique continuum that portrays both how individuals move through levels of development in a given domain and how their creative products affect the world. There are five levels in this continuum: universal, cultural, domain specific, idiosyncratic, and unique. Universal development is the type of cognitive growth that emerges without instruction and across all cultures, such as learning to conserve number and substance. Cultural development is the result of growing up in a given context, such as celebrating Thanksgiving in the United States. Subcultural experiences, such as specific manners, dress, or habits of speech also fit here. Adults in the environment teach children this information by offering them encounters with cultural events, values, or practices, but without formal instruction. Domain-specific development requires instruction by skilled teachers whose pedagogical skills and familiarity with a field help the new learner become competent within that field. Learning to play the flute, use a computer, play chess, or ski are examples. Sometimes informal learning rather than formal instruction can introduce the child to key ideas in a domain, such as a book about plant genetics devoured by a child who is raising questions, as was the case with Roberto Burle Marx, a renaissance Brazilian best known for his work in tropical landscape. Idiosyncratic development occurs when a learner reaches high levels of accomplishment in a given domain. At this point, the individual may develop distinctive movements in skating, characteristic phrasing in piano-playing, or mastery of a surgical technique that is different from the repertoire of most other surgeons. Finally, at the unique level, the individual has mastered a field so completely and created such original products or performances that his or her influence on a field requires new learners to learn the field in its transformed state. A performance by pianist Vladimir Horowitz or dancer Judith Jamieson, or Einstein's theory of relativity are examples of accomplishments that emerge from the unique level of development. The more the influence of a unique accomplishment works its way back down the Universal-Unique Continuum towards cultural or even universal levels suggests its value to the world. At this level, Feldman emphasized adaptation by the world to the individual.

From yet another theoretical vantage point, psychologist Robert Sternberg provided an extensive and integrative definition of adaptation. His Triarchic Theory of Intelligence portrays integrative relationships among three subtheories: the componential, the experiential, and the contextual. The componential subtheory relates intelligence to three types of information-processing components within the mind of the individual: metacomponents (higher-order executive thought processes), performance components (lower-order processes that serve as tools for the metacomponents), and knowledge-acquisition components (enable the individual to learn how to do what the metacomponents and performance components eventually do).

The experiential subtheory connects intelligence to experience. Effectively dealing with novelty and automatically processing information (automaticity) are signs of intelligence. An individual who does things automatically efficiently conserves mental resources that can be allocated to dealing with novelty, such as focusing on phrasing, rather than the notes in a piano sonata. Conversely, a person who effectively deals with novelty can apply more intellectual resources to automatization. Thus, adaptation can improve through experience.

The contextual subtheory relates intelligence to a person's external world. People may choose to exercise their contextual intelligence in one or more of three ways. They may adapt to an existing environment, shape that environment to better suit their needs, or leave the environment in favor of one that better suits their abilities and aspirations. For example, if workers feel trapped in a confining work setting, they can adjust their own beliefs and behaviors to fit in with the system, they can unionize to force the system to adapt to their needs, or they can quit and seek more rewarding employment elsewhere. In Sternberg's theory, we begin to see intelligence and adaptation linked by these three emphases on context: fitting in to, modification or shaping of, and selection of an environment.

Intelligence and Creativity: A Convergence of Perspectives Around Issues of Adaptation to Novelty

In these theoretical approaches linking creativity and adaptation, discussion of intelligence is necessary. Theories of intelligence deal with the ability to adapt successfully to the environment and to solve problems related to one's particular setting. Art Costa, an expert on thinking strategies, describes intelligent behavior as what one does when one does not know the answers. Facing a new situation in the environment, what types of responses would be appropriate?

This is an important starting point for a comprehensive understanding of creative adaptation, as theories of intelligence have been evolving in an interesting direction in recent years. Theories developed by psychologists Howard Gardner and Robert Sternberg emphasize multiple abilities and modes of information processing, modified by cultural context. They also focus on modification of the environment to meet the individual's needs rather than merely the reverse: the individual adapting to the environment. It becomes evident that theories of intelligence and theories of creativity are converging. Recent theories of intelligence are moving toward including creativity because they are concerned not only with the individual's capacity to adapt to the world, but also the ability

to shape or transform it. Theorists now are recognizing the pivotal role of creativity in intelligent adaptation.

Moreover, older theories of intelligence focused on adaptation to the environment. In recent theories of creativity, the adaptation is mutual. The creative person must master a field sufficiently to be able to see the problems or gaps at the 'edges' of the field. As Howard Gruber explained, 'It is safe to say that no case of early achievement occurs without a long apprenticeship.' This is adaptation to the world. But when creative individuals extend or transform the domain in which they function, that world of endeavor adapts to the creator. For example, when Freud described the workings of the unconscious mind, he changed the way new psychology students learned the knowledge base in their field.

Such creative transformation of the world requires wisdom and an ethical commitment to its betterment, according to Don Ambrose and Tracy Cross, as well as Robert Sternberg. It also involves a transformation of self that enables the individual to grasp the edges of a field, and that provides the courage and will to construct a point of view. The most recent theories of intelligence incorporate creativity by acknowledging this shaping-of-the-world aspect of adaptation, but they do not address the transformation of self.

Research and Scholarship on Adaptation and Creativity: Style, Expertise, and Chance

Creative adaptation and adaptiveness are related to cognitive style, development of expertise, and chance factors, discussed in this order.

Creative-Adaptive Styles

The research literature connecting adaptation and creativity is meager with the exception of the work of Michael Kirton and colleagues. Kirton hypothesized that there are two distinct types of creative people. He developed a scale to distinguish cognitive style preference, the Kirton Adaption-Innovation Inventory (KAI). The pattern emerging from this research suggested that creative adapters and creative innovators are types of creative people with quite different cognitive styles, which can be disadvantageous or advantageous, depending on the context. Structure is a key to the style differences. Those who prefer more structure are adapters while those who prefer less are innovators. However, either too much or too little structure inhibits generation of new thought or action. Innovators prefer situations that allow them to do things differently while employing looser cognitive structure. Innovation has a meaning of breakthrough change, or breaking out of a paradigm into another structure. Adapters prefer structured situations. They are interested in refinements of existing products, processes, or ideas. Their focus is on redefining, elaborating, modifying, and improving a paradigm.

Kirton made clear that innovation is not the 'best' nor the highest form of creativity. The appropriateness of a given style is dependent on a specific context and a given situation. When faced with a difficult context that demands other than the preferred style, individuals must use coping behaviors to bridge the gap between their preferred style and what is

perceived as necessary to achieve goals. Excessive demand for a different cognitive style usually results in the individual wanting to leave the situation. Yet Geir Kaufmann argued that Kirton's theory does not distinguish between novelty on the stimulus side and on the response side. He differentiated between reactive and proactive creativity, based on the novelty of the problem and problem sensitivity, rather than just the personal style of the creator.

Creative Adaptation and Expertise

Bruce Shore, Gillian Resjkind, and Lannie Kanevesky used recent findings in cognitive research to illuminate linkages among various conceptions of giftedness, creativity, and expertise. As with Sternberg's experiential subtheory, this work relates to creative adaptation because the cognitive abilities and habits of experts usually make them much better adapters than are neophytes or novices. Experts have mastered the knowledge base and skills of a field; hence, the thought processes necessary for efficient problem solving, adaptation, and innovation have become automatic. By contrast, neophytes and novices, with some rudimentary knowledge of the field, have not developed automaticity nor the necessary knowledge and skills. Consequently, they are not efficient adapters within that field.

Of course, questions arise about the degree of automaticity an expert can muster when confronted with a profound paradigm shift in a field. Standard knowledge and practices could become hindrances that lock an expert into ineffective actions when a paradigm shift changes the operational rules of a profession. In most situations, however, the experts' large accumulation of knowledge and skills provide them with strong adaptive advantages including (a) problem-solving flexibility, (b) effective use of prior knowledge, (c) strong associative and interdisciplinary connection-making capacities, (d) the ability to develop and follow effective action plans, (e) the ability to understand and use the context of a problem, and (f) meta-cognitive strength, or the ability to monitor the effectiveness of one's own thought and actions.

At the same time, development of expertise is probably not sufficient for renaissance types of creativity. I analyzed two major trajectories in creative lives that form a continuum, the linear, focusing on development of expertise and the network type, connecting diverse fields. In my study of two creative brothers representing each of these trajectories, I noted the pulls from each end of the continuum, the interplay of circumstance and context relative to adaptation, and a somewhat different development of expertise in the network trajectory.

Creative Adaptation and the Element of Chance

Abraham Tannenbaum described a dynamic interplay between chance and ability in the fulfillment of one's potential. According to Tannenbaum, chance is one of five factors that combine to influence development. There is a static element of chance, which includes things the individual cannot control, such as the accidents of genetic inheritance, or birth into a family of privilege or deprivation. There also is a dynamic element of chance, which includes things the individual can influence. For instance, rather than merely accepting their lot in life, people

can actively and randomly explore new ideas or work processes. Although randomness may be inefficient, it can lead to 'lucky' breaks. Those who actively prepare their minds according to perceived trends in their environmental contexts are likely to be even more 'fortunate' than those who simply employ random activity. Those who are most fortunate, however, are the few who develop a facility for luck through highly individualized action. They develop unique perspectives from which to view problems and their environmental contexts. These perspectives enable them to encounter opportunities more frequently than those who lack unique, individualized vantage points.

Recent developments in the emerging science of complexity add new dimensions to the influence of chance on creative adaptation. Complexity theory involves interdisciplinary studies of complex adaptive systems. Of most interest to complexity theorists such as Stuart Kauffman and Doyne Farmer are the ways in which order spontaneously emerges from apparent chaos. Complex adaptive systems, such as human minds or international political and economic systems, can be strongly influenced by minor environmental fluctuations; yet these systems seem to settle into patterns of order that enable them to adapt and thrive in changing conditions. High-powered computers and mathematical analyses are helping these theorists discover meta-patterns in the activity of complex adaptive systems. Given the existence of these patterns, it is likely that pattern finding in the midst of apparent chaos enables individuals to survive and thrive in complex, changing conditions. If so, 'good fortune' may be more dependent on intuitive pattern perception than on the elements of chance, at least in some conditions.

Whether people are blessed with socioeconomic status or earn more opportunities through activity, preparation of mind, or development of useful perspectives and pattern-finding abilities, the element of chance can affect creative adaptation. Those who are more fortunate are more likely to adapt successfully to problems, or to force adaptations in the environment that better suit their needs and desires.

Assisting Adaptation: Facilitative Contexts and Environmental Support

According to Lev Vygotsky, a Russian psychologist, mediation is needed to help the individual become adaptive and creative. Vygotsky posited that caring individuals are needed to help young learners interpret new knowledge. The 'zone of proximal development' is the conceptual space in which such interventions are most effective, the discrepancy between the children's actual mental age and the problems they can solve with assistance. Vygotsky found that instruction leads development and assists in the ripening of knowledge structures. Therefore, adults play an important role in mediating the learning process by providing hints, guidance, and correction. Through interactions with the mediator, the child internalizes problem-solving processes, thereby becoming better adapted to dealing with problems in the environment. Ideally, as the child becomes more able to generalize and transfer what is learned, the adult becomes less of a guide and more an encourager.

Psychologist, Reuven Feuerstein, also stressed that mediation plays an important role in adaptation. Feuerstein noted that intelligence is dynamic and modifiable, not static. In efforts to help the Israeli army find ways to improve the intelligence of ‘retarded performers,’ he posited that direct intervention in an individual’s cognitive development through mediation by an adult optimizes the effectiveness and efficiency of that development. He also suggested that lack of mediation can result in retarded performance. The intelligent person is able to effectively gather needed information and use that information to solve problems, or to generate new information. Through the benefit of mediation, the individual becomes more open to experience and more adaptable to new situations.

Both Vygotsky and Feuerstein focused on the role of the adult in interpreting both the inner and the outer worlds for the child in order to assist in the adaptive process. For instance, when a parent says to her 3-year-old son, “You are really angry that Sammy took your truck. Could you think of another way of getting it back, instead of hitting him?” the description of the child’s feelings and experiences helps him adapt to both the specific situation and to other similar occurrences. Such early mediation appears to promote successful adaptation to the world, and may even promote creative development.

Mediation provided by caring others also may support the work of mature creative people. Gruber’s studies of highly creative individuals suggest that social support is essential for full development of creative ideas. For example, in his study of Charles Darwin, Gruber found that Darwin’s concerns about contradicting the social values of his time, as well as his desire for social support, inhibited completion of *The Development of Species* for some 20 years. This can be construed as a desire for mediation – the need to discuss and share with like-minded others, or with those more knowledgeable who can facilitate thinking. It may be that mediation early in life prepares the individual for adaptation to the environment while allowing the individual the internal freedom to modify that environment. Paradoxically, however, enough tension, adversity, and challenge need to be present to develop adaptive strategies. And at the same time, the creator must interpret the cultural and contextual boundaries and what might be accepted or rejected out-of-hand.

A Continuum of Adaptive Creative Behaviors

In the previous two sections, one emphasis has been on adaptation and the creative person, with particular focus on cognitive style. Another emphasis has addressed a contextual aspect – the facilitation needed to fully nurture both adaptation and creative development. In this section, we explore another continuum, one that addresses adaptation in context, as well as the creative process and product. Linkages are needed to connect childhood creative adaptation to the type of creativity seen in eminent adults. Another bridge is needed to explain the more mundane creativity found in the everyday lives of adults. I suggest that one way to build these bridges is to think of creativity as a range of adaptive behaviors along a continuum of seven developmental levels. This continuum can help explain the processes and progress of creativity itself.

The Common Element in the Continuum: Discontinuity

Common to all levels on this continuum is the notion of a discontinuity between what was before and the new. It is what Gregory Bateson, Bertrand Russell, and Alfred North Whitehead described as a ‘jump in logical types’ from the particular to the general, that results in a new context. Piaget defined this leap as ‘reflective abstraction,’ a process of reflection and putting events or thoughts into relationship, which leads to new understandings not inherent in the thoughts or events themselves.

In this Continuum of Adaptive, Creative Behaviors, the variables hinge on six aspects related to context, process, and product, as described in [Table 1](#).

The seven levels of the continuum of creative behaviors

At one end of the Continuum is Level 1, Learning something new: universal novelty. This type of creativity occurs in infants, children, and adults as they deal with newness in their world. At the opposite end of the continuum is Level 7, Creating by transforming a field. This level of creativity is found only in a few individuals. In between are levels that connect the universal creativity of childhood to eminent creativity.

Table 1 Variables in the continuum of adaptive creative behaviors

Aspect	Variable	Description
Context	Adaptation	Initially, creativity involves adaptation of the individual to the world. At the highest levels, it involves adaptation of the world to the individual. This shift occurs between Levels 4 and 5
Process	Purpose	The creator’s purpose shifts from mastery to extension, and finally to transformation
Process	Speed	Creativity is rapid in early levels, involves more time in each increasing level, and involves living a creative life at the highest levels in which one’s major focus is on creating, requiring many years of effort
Process	Structure	Initially, the mental structures are very incomplete and creativity involves construction of these structures. At the opposite end, the structures are very well-developed, and the individual sees gaps, lags, and conflicts – limits to the present level of understanding. Early levels of creativity involve simple structures, a single domain or scheme. Later creativity involves major structural reorganization and transformation. The goal is to push out the edges and to transform the structures, constructing a point of view
Product	Novelty	In the first level, creative products or ideas are new to the individual. They become rare compared to age-peers, offer new combinations of others’ ideas, and finally, are considered new and transformational to the world at the two highest levels
Product	Value	The creative product is of value initially to the self, then to others, and finally, to the world

Level 1: Learning something new/universal novelty

Individuals construct relationships new to themselves, but not new to the world; also mundane, mini, or little c creativity. All new learners of a field make the same constructions. *Examples*: conserving number; learning to push off the ice when skating the first time.

Level 2: Making connections rare compared to peers

Individuals develop products, ideas, or approaches that are unusual compared to peers but are not new to the world. *Examples*: a 4-year-old on a city walk focuses on a pile of broken glass. 'Look,' she says, "here is a city with all the buildings and busy people. And see this piece? This is a lonely child"; envisioning an onion to conceptualize the layers in Bronfenbrenner's ecological theory.

Level 3: Developing talents

Individuals connect to and develop skills in one or more domains, moving through a series of stages in which abilities are honed, accumulated knowledge of a field is learned, and craftsmanship developed, usually requiring expert teachers. Individuals experience compulsion to work hard in the area of interest, setting a variety of challenges to themselves. When heredity and environment inextricably combine, a child's products or abilities may approach adult levels in prodigious development. *Examples*: becoming good at athletics, art, mathematics, writing, or fixing cars; playing violin with the NY Philharmonic at age 10.

Level 4: Developing heuristics

Through instruction, individuals develop strategic ways of thinking in the domain, such as creative problem solving, critical thinking, and metacognition, wherein the preferred ways of working and habits of mind are identified and cultivated. This level probably develops simultaneously with Level 3, Developing Talents. *Examples*: using fantasy and imagery in writing; focusing on aesthetics to develop stronger awareness of beauty, harmony, and patterns.

Level 5: Producing information

Individuals discover and investigate their own real problems or burning questions related to areas of interest and developing knowledge, producing new information that is valued by self and others, although the scope is limited to an arena 'close to home.' The individual's views begin to be imposed on the world. Adaptation starts to shift from making self fit the world to changing the world a little by one's ideas and efforts. *Example*: a fourth grader logs weights, measurements, behaviors, and daily photographs of the changes in their husky's litter of puppies over 8 weeks, publishing their research in a children's magazine; an elderly citizen, moved by the plight of the homeless, rallies a community to help.

Level 6: Creating by extending a field

Individuals, having mastered a domain to be aware of gaps, problems, or pressing issues, add a new dimension or valuable information to that field, thereby extending that domain of endeavor, as well as constructing a partial point of view. *Examples*: developing a new technique for surgery; writing an award-winning dissertation.

Level 7: Creating by transforming a field

Individuals, labeled geniuses or renaissance persons by society, revolutionize a field or create new ones by combining different aspects of endeavor. At this level, the field, and possibly even the world, adapts to the creator by passing on the transformation to new learners, contributing to a paradigm shift. Both individuals' internal knowledge structures and the external environment in which they work are transformed, a unique point of view is constructed, and the product is highly valued. *Examples*: Piaget's equilibration theory; Roberto Burle Marx's contributions to tropical landscape design.

What most people consider creativity – production of something new or very rare to the world that is of value – is reserved for Levels 6 and 7 on the Continuum. Creativity at these levels is called 'mature' because it involves well-developed, extensive, and intricate knowledge systems representing mastery of a field typically requiring 10 years of effortful study and practice to reach such levels, according to Mihalyi Csizentmihalyi. In addition, this type of creativity involves the regular solving of problems, not a one-time occurrence, according to Howard Gruber. Ethics become very important at these levels. Creative products such as nuclear power or genetic engineering may be valuable when they are produced, but their long-term effects are unpredictable and potentially disastrous. Those with the most creative potential carry the greatest moral responsibility for the ultimate effects of their creative thought, as noted by Ambrose et al. and by Sternberg.

In this Continuum of Adaptive Creative Behaviors, the shift in adaptation occurs between Levels 4 and 5. Prior to this point, the individual has been adapting to the world. In Level 5, the world begins to adapt a bit to the individual. To make such a shift usually requires facilitation from knowledgeable and supportive adults, as well as the building of a knowledge and experience base. School and work settings that encourage autonomy, freshness of vision, and originality; the development of talents and multiple strategies for thinking; as well as purposeful, self-set effort help individuals make the shift and can lead to mature levels of creativity.

Conclusions and Issues

Creative adaptation involves highly complex dynamics that depend on a wide range of situational and cultural constraints. It involves both short- and long-term thought, action, and development. It brings forth transformations within the individual as well as modifications, or even paradigm shifts in the environmental context. It also involves a wide range of cognitive, emotional, and motivational elements. In short, virtually all human faculties are called into play during creative adaptation to environmental problems and opportunities. Ultimately, adaptation is one of the most important issues of relevance to the development of creativity.

Successful creative adaptation involves a number of paradoxes. Creators need to destroy existing structures while maintaining safety and harmony within the environmental and cultural context. They must make major transformations to their own cognitive structures while remaining resilient in the face of the inevitable attacks that accompany creative work.

They must perceive pressing and immediate problems and opportunities in the environment while staying focused on a long-term sense of purpose. This requires creative balancing of self in the environment, 'reading' the cultural and contextual requirements and demonstrating adaptiveness as well as developing original ideas. If one merely adapts to the will and the world of others, it is unlikely that highly creative products can result. If on the other hand, the distance between the world and the individual's created product or performance is too great, 'pearls may be cast before swine' and the world will not recognize the breakthroughs. Bucking prevailing paradigms or cultural norms is always difficult if not dangerous. Individuals have been relegated to mental institutions and even tortured or killed for such differences in perspective. Although such penalties were more prevalent in the past, anyone who has tried to get major research funding for a 'far out' idea faces the problem of critics who simply cannot escape their own world view.

It is the long-term development of the individual along the Continuum of Adaptive Creative Behaviors that enables the resolution of these paradoxes. The broader, more integrative cognitive structures and stronger sense of purpose one develops through progress along the Continuum help provide resilience and competence necessary for successful adaptation of both self-to-world and the world-to-self, even in the face of the difficulties imposed by creative work.

All of this raises one final issue relevant to considerations of creative adaptation. To what extent should the creative adaptation of one individual or group impinge on the opportunities for success of another individual or group? This question brings into play profound issues such as individual freedom, social Darwinism, class conflict, exploitation, cultural context, and the moral-ethical implications of creative products and processes. In a postindustrial era of rapid, unpredictable change our answers to this question may determine our chances for successful creative adaptation as a species.

Glossary

Advertising A paid, mediated form of communication from an identifiable source, designed to persuade the receiver to take some action, now or in the future.

Art Works embodying human expression, characterized primarily by the manner of their creation and/or execution, irrespective of the presence or absence of concepts, ideas, messages, or functions underlying them, conveyed by them, or achieved by them.

Introduction

What Is Advertising?

Numerous definitions of advertising exist. Some are broad, like the definition provided by James Laver who proposed that:

Advertising is as old as Humanity: indeed, much older; for what are the flaunting colours of the flowers but so many invitations to the bees to come and 'buy our product'. Everything is already there: the striking forms, the brilliant hues, even the 'conditioning of the customer'. . . . Advertising might be defined as any device which first arrests the attention of the passer-by and then induces him to accept a mutually advantageous exchange.

A more narrow definition was presented by Raymond Williams in his classic essay entitled 'Advertising: The Magic System' in which he described advertising as "the official art of capitalist society."

In the opening paragraph of his book *Ogilvy on Advertising*, advertising legend David Ogilvy, wrote:

I do not regard advertising as entertainment or art form, but as a medium of information. When I write an advertisement, I don't want you to tell me that you find it 'creative'. I want you to find it so interesting that you buy the product. When Aeschines spoke, they said, 'How well he speaks'. But when Demosthenes spoke, they said, 'Let us march against Philip'.

Leo Burnett, another advertising legend, describes advertising from a competitive standpoint as "selling corn flakes to people who are eating Cheerios."

When advertising and marketing experts were brought together by researchers Jef Richards and Catherine Curran and asked to collectively decide what advertising was, they arrived at the following definition:

Advertising is a paid, mediated form of communication from an identifiable source, designed to persuade the receiver to take some action, now or in the future.

Why Advertise?

Advertising has many different uses: to create and promote the image of a corporation, product, or brand, to make an announcement, to make a sale, or to support a cause. The primary goal of advertising is persuasion. It is extensively relied

upon to promote products and services, charitable causes, individuals like politicians and celebrities, and even ideas. As a marketing communications tool, advertising is a critical element of the integrated marketing communication mix.

Russell and Lane propose that advertising is an institution, not merely a means of disseminating information about a product. They argue that advertising impacts consumers, businesses, and society. Advertising provides information to consumers that allows them to discriminate between products. It allows businesses to bring new products to the attention of enough consumers so as to enable them to stay in business. In this manner, it fuels the economic engine of society.

The money businesses spend on advertising has increased dramatically in recent years. In 2007, spending on advertising has been estimated at over \$150 billion in the United States and \$385 billion worldwide, and the latter to exceed \$450 billion by 2010. However, marketers are faced with increasing challenges as well, including a squeeze on profitability, increased advertising clutter, and the complexities involved in communicating with diverse target audiences.

What Is the Role of Creativity in Contemporary Advertising?

Consumers are bombarded with images wherever they turn, via TV, the Internet, smartphones, billboards, magazines, and so on. It is difficult for marketers to compete for the attention of consumers under such conditions. Increased spending on advertising has resulted in increased advertising clutter and consequently a struggle by marketers to have their message seen and heard. Indeed, under these circumstances, the importance of creative solutions to cut through the clutter is becoming increasingly evident.

Creativity is considered a product of human intelligence characterized by originality, expressiveness, and imagination. Thus, creativity in advertising may engender original, expressive, and imaginative ads. These ads may be funny, clever, unique, or exciting, but any 'wow, I love that ad' response evoked in a consumer must also translate to a 'wow, I love that product' response. What differentiates creativity in advertising from other types of creativity is that it must be employed to meet marketing objectives. Thus, effective advertising results from the interplay between creativity and strategic consumer insight.

Technological developments are revealing new opportunities for enhancing creativity in advertising. Many historical

inventions, such as photography, the printing press, television, or computers, have revolutionized the landscape of advertising, but new technologies are constantly emerging, and arguably more frequently now than in the past. For instance, computerized design tools, morphing and digital special effects, digital video-editing, holograms, 3D effects, virtual reality, multimedia presentations, ink-jet personalization, public relations planning software, and interactive media are changing the face of how advertising is done. Indeed, one of the ways that advertising professionals facilitate their own creativity is by staying abreast of the newest technological developments. In their efforts to remain competitive, advertisers must attempt not only to stay abreast of these developments, but also to apply them creatively in the marketing of products.

The Visual Element in Advertising

The effectiveness of an ad is a function of what is said and how it is said. Several creative elements – the visual, the copy, the music – come together to create a successful advertisement. Although a lot of research has been done on these individual elements to determine what works and what does not work, there are no formulas for success and few ways to measure truly creative advertising ideas. According to a handbook published by Ogilvy and Mather, to get an ad right you need two things: (1) a simple, inspiring, insightful strategy and brief, and (2) the time in which to do the work right.

A great deal of literature has discussed how the different elements of advertising work. In this article, we focus on the visual element of advertising. Investigations regarding how the visual element can help enhance the effectiveness of the advertisement have been undertaken since marketers began to adopt full-scale marketing activities in the late nineteenth century. In this article, we will review some findings from this literature and then narrow our focus to a special category of visual images, namely, visual art.

Importance of Visual Images in Advertising: Evidence from Academic Research

Kosslyn et al. report that two-thirds of all stimuli reach the brain through the visual system, and it might be argued that although human thought is neither words nor visual images, it seems closer to the latter than the former. This finding is poignantly reflected in Cahners Advertising Performance Studies which find that 98% of the top scoring ads in advertising effectiveness contain some visual element, either a photograph or an illustration. This visual element occupies between 25% and 63% of the layout space. Of the top-scoring ads in this study, 65% had a visual that occupied between a quarter and three quarters of the advertisement.

Visual images are used to attract attention, stimulate curiosity, illustrate product features and benefits, create and develop a personality for a product, associate the product with certain symbols and lifestyles, and establish a brand's identity in the minds of the target audience. Research findings suggest that the content or what is depicted in a visual image is an obvious influence in the overall evaluation of the brand. For instance, advertisers use visual imagery to enhance or strengthen the

message about their product. When something neutral (the product) is paired with something that elicits a positive affective reaction (a visual), the positive qualities of the visual may be interpreted by the consumer as also belonging to the advertised product.

Eye-tracking studies have been used to show that consumers focus first on the dominant picture in a print ad before attending to verbal information. The attention a viewer pays is facilitated by (a) the size of the image, where larger pictures work better than small ones, (b) the color of the image, where a color image works better than one in black and white, and (c) the vividness of the image, where a greater number of colors works better to attract attention.

Rossiter and Percy divided visual communication in advertising into two categories of stimuli – static and dynamic. The three elements that determine static stimuli are picture size, exposure duration, and number of exposures. An increase in any of these variables has been shown to increase recognition, encoding of details, and development of denotative images among viewers. Although the attributes of static stimuli do not fit perfectly in measuring dynamic stimuli, this latter type also has resulted in high viewer response.

A 'picture-superiority effect' has been established in the literature. This implies that images in ads (a) facilitate memory of ad content, (b) favorably influence beliefs, attitudes, and behavioral intent, and (c) increase involvement with the product.

How the Visual Component of Advertising Works

It is relatively well established that visual images have an influence on the effectiveness of advertising and the evaluation of the products being advertised, but it is less clear how this influence is exerted. It has been suggested that the visual component of advertising performs two key functions – literal and symbolic. Literal visuals provide factual information about products or services (e.g., a photograph of the product itself), and symbolic visuals perform an indirect role to connect the images of products or services with the meanings that are appropriately assigned to them (e.g., a fluffy kitten to connote softness). Indeed, visual images can convey semantically meaningful concepts via their stylistic properties. These stylistic properties may result from a variety of different factors such as camera angle, depth of focus, color treatments, orientation of depicted products, and so on. The descriptive concepts thus conveyed may serve as central arguments of an advertisement, such that the stylistic properties are instrumental in the influence of the ad on consumers' perceptions of the advertised product.

A great deal of research appears to be based on the assumption of a relatively effortless comprehension of nonverbal ad elements. Mitchell and Olson illustrate that brand attitudes arise from a classical conditioning effect using a valenced visual image, rather than from a more elaborate interpretation of the image. Miniard et al. investigate the influence of emotional appeals on brand attitudes by utilizing affect-laden or emotion-filled images that they argue are devoid of product-relevant information. Hagtvedt and Patrick demonstrate that although the content of a visual image is a source of interpretable information, art images have a general influence on consumer evaluations, regardless of the specific content of the images.

Previous research has also demonstrated that perceptual fluency (or the ease with which an image is processed) results in enhanced consumer judgments.

Some research has relied on theoretical domains such as semiotics and rhetoric to explain how consumers extract information from a visual image. Semiotics refers to the communication of information via 'signs' that combine to form a meaningful 'text,' the interpretation of which includes the decoding of these signs according to culturally based decoding rules. A sign may be iconic and thus have a physical resemblance to its meaning (e.g., a photograph of the advertised product). Otherwise it may be symbolic and thus relate to its meaning by arbitrary convention. This type of sign is not an obvious, physical representation of its meaning. A sign may also be semantically related to its meaning via index (e.g., smoke as an index of fire).

Hagtvedt and Patrick assert that visual images are characterized by two key components: (1) content (*what* is depicted) and (2) manner (*how* it is depicted). These authors present a theoretical framework to understand the impact that visual images have on persuasion. This dual-process model proposes that when the content of an image is salient, the image is processed analytically as a product-relevant illustration, but when the manner is salient, the image is processed heuristically as an aesthetic stimulus. For instance, one might imagine two individuals looking at an ad for a beach resort in which the visual image in the ad is a painting of a woman on a beach. One individual looks at this image and sees a woman on the beach, while the other individual looks at the image and sees a painting. In other words, these two individuals look at the same image but focus on two different components of it. The first focuses on the content of the image (*what* is depicted) while the other focuses on the manner (*how* it is depicted). This differential focus may lead to vastly different influences on the consumers' perception of the beach resort. Thus, this dual process model represents a means by which to systematically disentangle the influence that the two components of content and manner have on consumer evaluations of advertising and products associated with the advertising images.

Individual Differences in Response to Visual Images

The effects of the visual element of the ad may be different depending on an individual's response to visual (vs. verbal) elements and/or the consumer's ability to generate vivid mental images. The visualizer/verbalizer cognitive style describes individual preferences for attending to and processing visual versus verbal information. In general, visualizers are characterized as those individuals who have high imagery ability and vivid daydreams, who like illustrations, diagrams, and charts, who prefer to be shown how to do something, and who tend to be more subjective about what they are learning. In contrast, verbalizers have lower imagery ability, like reading text or listening, prefer to read about how to do something, and tend to be more objective about what they are learning.

Several scales have been developed to measure dispositional imagery abilities. The Betts Questionnaire Upon Mental Imagery (QMI) is designed to assess individual differences in imagery vividness in regard to visual, auditory, gustatory, olfactory, and organic modalities. The Vividness of Visual Imagery

Questionnaire (VVIQ) assesses imagery abilities in regard to only visual images. Notably, dispositional differences in response to visual elements have been demonstrated to have a significant effect on creativity and information processing. Bone and Ellen demonstrate that participants' ability to imagine/visualize had an effect on (1) the reported vividness of the image of consuming the advertised brand and (2) the subjectively perceived ease of imagining experiencing the product. These two variables in turn had a significant impact on the attitudes toward the advertised brand.

Childers et al.'s Style-of-Processing Scale is an instrument that reflects consumers' relative tendency to process information visually or verbally. The processing style relied on may depend on both chronic differences and situational differences. Research has indicated that chronic differences in processing style have virtually the same effects on the processing of product information as does situationally primed differences. However, the latter type of differences suggest that both visual and verbal processing strategies exist independently as part of procedural knowledge and that their relative accessibility decides which processing style is relied on at any given moment.

Visual Art: A Special Case of Visuals in Advertising

Visual art is used extensively in advertising. Indeed, Hoffman reports that "reproductions of high-culture images reach more people more often through advertising than through any other medium." However, although the use of art is widespread in advertising, the various manners in which it may be used have not been systematically studied. It therefore seems instructive to provide an overview of how visual art is incorporated into advertising, as well as to pose questions about how this use of art influences consumers. Increased knowledge in this area should also assist advertisers in using art strategically and systematically rather than in an ad hoc manner based predominantly on intuition and experience.

Depending on definitions, one might argue that advertising is about selling, while art is about revealing; advertising is commerce, while art is culture. Advertising is usually intended to get a specific reaction from consumers, while works of art are often ambiguous, inviting multiple interpretations and meanings. Such suppositions notwithstanding, art has been used to influence people in specific ways throughout history.

Leaders like the Egyptian pharaohs, Roman emperors, and the popes used art for various purposes such as selling religion, promoting their own image and prestige, and enhancing their positions of power. Similarly, the Medici of Florence used art to promote a philosophy of enlightened humanism, as well as to impress their clients and business connections. In the current era, the use of art in such promotional endeavors is perhaps more prevalent than ever, for two main reasons: first, art is affordable and available to a larger number of people now than it was in earlier times and second, the popular use of imagery is facilitated by modern media and channels of distribution. Perhaps the difference between high art and popular culture has also gradually eroded in our consumption society, or perhaps it is a lingering distinction that still makes art useful in advertising. Either way, before we can speak sensibly about the effect of art in advertising, we must first specify what constitutes art in the current context.

What Is Art?

The notion of art as a special category is itself a relatively modern idea. For instance, not before the mid-eighteenth century did Abbé Batteux present the separate classification of fine arts made up of music, poetry, painting, sculpture, and dance. A distinguishing mark of these disciplines was that they had pleasure rather than utility as their goal. Today the notion of art as a separate category still remains, along with a belief that the perception of art differs from the perception of other objects. However, although a great deal of research has been focused on this perception, different definitions abound, and it seems doubtful that scholars will ever agree on any particular one. When speaking of art in connection with advertising, however, it seems appropriate to define art from the consumers' perspective: that art is that which is categorized by the viewers as such. Further, we will here restrict ourselves to visual art.

Even with this definition, it seems reasonable that differences in opinion will exist as to what distinguishes something as a work of art. On average, however, consumers do appear to possess some consistent views of what does or does not constitute art. Research conducted by the authors has indicated that the average viewer is able to recognize certain characteristics that distinguish artworks from other human creations. Indeed, consumers consistently report that art images are expressive, that the manner of creation or execution is itself a central feature of an artwork, while just trying to say something or express an emotion without a 'special' manner is not enough to constitute art. This manner tends to be characterized by the skill and creativity applied to the creation of the artworks. Based on these self-reports and on a thorough review of art history, the authors propose that art may be identified as works embodying human expression, characterized primarily by the manner of their creation and/or execution, irrespective of the presence or absence of concepts, ideas, messages, or functions underlying them, conveyed by them, or achieved by them. Therefore, typical conceptual works such as animals in formaldehyde, human feces in hermetically sealed cans, or even Marcel Duchamp's famous urinal 'Fountain' (considered in a survey by CNN to be the world's most influential piece of modern art) may not spontaneously be recognized as works of art, unless they have already been marketed as such. These works typically depend on a context, such as being placed in a gallery, for their impact, and the cultural implications of, for instance, an institutional theory of art would detract from the focus of the current discussion. Further, works generally recognized as art, whether they are presented in a gallery or not, seem more useful for advertising purposes.

The Influence of Art in Advertising

Some research provides an understanding of the role of products with a salient aesthetic purpose, but the amount of extant research that illuminates the influence of art in the current capacity is quite limited. There is a need to further develop our understanding of how art images differ from other visual stimuli, and to map out how the presence of art influences consumer perceptions of products and brands.

Research conducted by the authors establishes the phenomenon of *Art Infusion*, broadly defined as the general influence of

art on consumer perceptions and evaluations of products associated with the art. General properties of art, tied to a special kind of quest for excellence inherent in the creation of artworks, spill over onto the products with which the art is associated. These properties cause perceptions of luxury, sophistication, and high culture to be associated with the product in question, leading to enhanced product evaluation. Further, although visual images are usually found to affect viewers in an affectively congruent manner, the Art Infusion Effect does not depend on the content of the image and occurs whether the valence of emotion elicited by the artwork is negative or positive. This distinguishes visual art from other sensory stimuli used in advertising, such as music, in which the valence of the stimuli has a congruent impact on evaluations.

In further research, visual art is also shown to have a favorable impact on evaluations of brand extensions. First, the Art Infusion Effect leads to enhanced brand image. Second, appreciation of visual art appears to cause enhanced cognitive flexibility, thus increasing perceptions of fit between the brand extension and the parent brand category.

If the artworks used in advertising are to have their intended influence, it is important that they are recognized and respected as artworks by the target audience. Indeed, popular and easily recognizable artworks tend to be relied on for advertising purposes. A large proportion of the ads feature European works created between the early fifteenth century and the mid-nineteenth century. Works stemming from the Renaissance, from Neoclassicism, and from Romanticism are well represented. Although well-known masterpieces are typically used, a style that clearly reflects skill and creativity may also be enough to convey the intended properties of the artwork, even when the specific piece is unknown to the audience. Possible gender differences should also be noted when considering the responses of the target audiences for advertising with art. Factors such as education, social class, and personality have a greater impact than gender on aesthetic activity and aesthetic attitude in general. However, men and women exhibit different preferences for, for instance, different styles. While women seem to prefer impressionist and rococo styles, men seem to appreciate expressionism, cubism, pop art, and abstraction more than do women.

The Ambiguous Language of Visual Art

Recent research in the emerging field of neuroaesthetics aims to understand the biological underpinnings of the human fascination with art. It may be argued that there are limits to how rich the information stemming from neuroscientific research can be on its own, but it may provide interpretable evidence when analyzed in combination with other experimental research, as well as with qualitative studies with converging evidence from fields such as art theory, psychology, sociology, anthropology, and marketing. Artworks are often ambiguous in nature, and research in neuroscience has found that this ambiguity is one of the fundamental reasons why a work of art engages the brain in the first place. Although the general insights given by the experience of an artwork may constitute a particularly interesting aspect of that work, openness to interpretation allows the viewer's brain to 'complete' the artwork for itself, and thus the commonalities in artistic

expression will be found by each individual viewer in a unique way. Indeed, Dewey argues that when viewing an artwork a spectator may experience creative processes similar to the ones of the artist who created the work. Does the open ended nature which often characterizes great art therefore contribute positively to the impact that art has on advertised products? How does this fit with the conception among advertising professionals that the best commercials leave something to the viewer's imagination?

A Typology of the Use of Visual Art in Advertising

O'Barr provides a review of the history of art in advertising. He outlines some of the earliest uses of art like Cruikshank's 1820 illustrations used in posters for Warren's blacking company, or the famous 1887 Pears ad with the 'Bubbles' painting by John Everett Millais. Today the use of art in advertising is widespread, and in the section that follows we will attempt to provide a typology for how visual art is being used in advertising. There are several ways in which categories for the use of art in advertising may be specified. Here they are specified by type of artwork, by the advertising appeal, or by the application of the artwork.

With these guidelines in mind, we perused a great deal of literature containing advertising, including books and journal articles on the subject, as well as a full year's (2005–2006) issues of various magazines, including *Architectural Digest*, *Businessweek*, *Cosmopolitan*, *Fortune*, *GQ* (Gentlemen's Quarterly), *New Yorker*, *Newsweek*, *Readers' Digest*, *Time*, and *Vogue*. After thus collecting a large quantity of advertisements with art, we attempted to identify general categories for the current use of art in advertising.

Type of Artwork

Figurative versus abstract

The majority of advertisements with art seem to use figurative art, in other words art which represents physical objects, people, or elements of nature. This may be because the majority of nonexpert viewers prefer representational images to abstract works.

Classical versus modern

In this categorization, classical may be thought of as most styles ranging from the Classical Greek sculpture of Pheidias or Myron to the Neo-Classical paintings of Jacques-Louis David. Modern may be thought of as later movements such as Surrealism or Abstract Expressionism. Some movements, such as Impressionism, would represent a grey area, and classifications would have to be made on a piece by piece basis. In general, classical art seems to have found more popular use in advertising than modern art has, and Hetsroni and Tuka-chinsky argue that the use of Renaissance artworks has been particularly prevalent. Indeed, Leonardo da Vinci's 'Mona Lisa,' Michelangelo's 'David,' and Botticelli's 'The Birth of Venus' are among the most popular images of all.

Famous versus unknown

The level of fame of the artwork may depend on the function the artwork is intended to have. For instance, if recognition value is the goal, then fame is obviously desirable. However, sometimes other criteria may guide the choice of artwork, for

instance if the advertisers want one that fits particularly well with a slogan or tells a specific story. In this case, a work of art may even be commissioned for the occasion.

Advertising Appeal

Serious versus humorous

Many advertisements with art have a serious approach. The aim may for instance be to convey an air of high culture or timelessness. In this manner, Rodin's 'Thinker' lends the gravity of art and philosophy to an ad for Dewar's, implying that this whiskey is more sophisticated than other drinks. Ads for Courvoisier often display paintings of Napoleon Bonaparte, underscoring the idea that this is the 'Cognac of Napoleon,' thus evoking both an imperial heritage and the timeless allure of French culture.

On the other side of the spectrum are the ads which use art for the purpose of humor. One ad features a painting by Fra Angelico, where the angel Gabriel informs the Virgin Mary that she will bear forth a child. Mary responds: 'Thanks, but I already know.' It is an ad for Clear Blue pregnancy tests.

Art-inspired versus product-inspired

There are popular conceptions about art itself which advertisers may wish to exploit. In an ad for Tabu perfume, artist and model are caught in a sudden, passionate embrace, thus linking the perfume to the emotional freedom and creative personality of artists.

Other times, art enables an advertiser to say something about product attributes which would otherwise be difficult to formulate. In an ad for Sungard, a painting of Hercules is explicitly used to symbolize the power of their systems. This also matches perfectly with the slogan: 'Rely on our strength.'

Nudity

Nudity and sex are employed in a variety of advertising contexts, but there are circumstances under which such a use would be considered improper, especially in a relatively puritanical country such as the United States. Here art comes to the rescue. One can often 'get away with' nudity if it is used in the context of art. For instance, Michelangelo's 'David' is the classic protagonist where full-frontal male nudity is concerned. The bare breasts of the 'Venus de Milo' seem harmless, even in a family friendly commercial for Kellogg's brand corn flakes, while Rest Assured mattresses emphasize comfort and user-friendliness by displaying sexual scenes from the Kama Sutra.

Application of Artwork

Mere presence versus integrated presence

Often a work of art plays a somewhat passive role in an advertisement. An ad for Pulsar displays the painting 'Spring' by Botticelli, tying Pulsar watches to the golden age of the Renaissance.

Other times the artwork is not merely displayed alongside the product. In an ad for Ikea, a naked old lady sits on a chair on her lawn, sipping refreshments. 'The Birth of Venus' by Botticelli is painted on the house wall behind her, seeming almost modest in comparison. In a Levi's commercial, Michelangelo's 'David' wears a pair of torn Levi's jeans. In a Fiat ad, Leonardo's 'Mona Lisa' is driving the car.

Telling a story with the artwork versus creating an artwork for the story

Sometimes an artwork is used to resonate with or underscore a story told by the advertisement. In an ad for the St Regis, Degas' painting of dancers viewed from the orchestra implies that guests may enjoy refined entertainment here. In an ad for Mercedes-Benz, Whistler's mother is implied to drive off in a fancy car.

Other times, a work of art is specially made to fit the product or a specific story. An advertisement for Pears' soap may be said to have started this tradition, with the first museum-quality painting used in modern advertising. The painting was just barely altered in that a bar of Pears' soap was discreetly placed at the bottom of a scene with a child blowing soap bubbles. Following this, many companies have employed artists to custom make artworks for their advertising campaign. The most famous of all is perhaps the enduring Absolut Vodka campaign.

Mimicking the original artwork: reminding versus parodying

It may sometimes be difficult to make the distinction between an image that was created to remind us of an artwork and an image that was created to parody an artwork. For instance, in an ad for Tela paper napkins, Leonardo's 'Last Supper' is imitated by a photograph with 13 young women at the table, arranged in a similar manner as Jesus and the disciples of the original fresco. Is it an irreverent parody, or is it a stylish photograph inspired by a masterpiece? Perhaps the answer depends on the intent of the advertiser or on the interpretation of the viewers.

Sometimes, however, the distinction is clearer. An example of an ad reminding us of a specific artwork may be a commercial for Campari, where a picture very similar to the painting of the 'Bar at the Folies-Bergère' by Manet displays bottles of Campari, rather than the indistinct bottles of the original painting. Beneath the ad are written the words 'Campari. Reflection on art.' The ad is serious, and the picture with the bargirl is clearly meant to mirror the original painting in an elegant and respectable manner.

In an advertisement for Prince sauce, the Mona Lisa appears in two versions side by side. In the first, she is very similar to the original painting, except that she is now holding a jar of original Prince sauce. In the second, she is obese, and she is holding a jar of chunky Prince sauce. The distortion of the original painting clearly identifies this ad as a parody.

Symbolic connection versus substantive connection

An ad for Shell features 'The Birth of Venus' by Botticelli, simply because she is standing on a giant sea-shell. Here, the representation of the shell is the only connection between the advertisement and the artwork.

In a different approach, several ads for De Beers display paintings from their collection, conveying the idea that diamonds, like paintings, are unique works of art. The ownership of the paintings establishes an intimate connection between the firm and the artwork, as well as highlighting De Beers as a collector and sponsor of the arts in general.

Summary

Advertising has been defined as a paid, mediated form of communication from an identifiable source, designed to

persuade the receiver to take some action, now or in the future. Thus, although advertising has many uses, its primary goal is persuasion, and creativity in advertising is employed to meet marketing objectives. As advertising clutter increases, it becomes increasingly difficult for businesses to find creative solutions to effectively communicate with consumers. At the same time, technological developments reveal new opportunities that facilitate this process.

Research has revealed that most effective ads contain some form of visual element. This is perhaps not surprising, considering the centrality of the visual system for supplying stimuli to the brain. Researchers have relied on various theoretical domains to explain how consumers extract information from a visual image. The responses to visual images may also vary among individuals, depending on, for instance, dispositional imagery abilities or visual versus verbal processing tendencies.

Visual art represents a special form of visual in advertising. It has been used as a tool in this capacity throughout history. What primarily distinguishes art from other forms of visual communication is the manner in which it is created or executed. This manner is recognized by consumers, and research has demonstrated that the favorable perceptions associated with artistic manner may spill over onto consumer products that are advertised in connection with artworks. The current article concluded with a typology of the use of visual art in advertising.

Glossary

Aesthetics A set of principles for judging beauty or pleasingness.

Effectiveness The extent to which a product does what it was intended to do.

Elegance A property of a product that makes it pleasing, beautiful, admirable.

Experimental aesthetics Empirical investigation of the interaction of beauty, perception, and culture.

Functional creativity Novelty that carries out a specific task effectively.

Genesis A quality of a solution to a problem that makes the solution transferable to other situations.

Indicators Properties of a product that demonstrate its functional creativity.

Quasicreativity Ideas that possess genuine novelty but are poorly adapted to the constraints of reality.

Relativity A property of aesthetic judgments which results in them being specific to a particular society and/or era.

Schemata Mental representations of external objects.

Subjectivity A property of aesthetic judgments which results in them being specific to a particular person.

Universal aesthetic A set of indicators of beauty capable of being applied in all domains such as fine art, science, business, and production systems.

The Nature of Aesthetics

Aesthetics involves questions of beauty. It is frequently associated with fine art, music, poetry, and similar activities. However, as Daniel Berlyne pointed out, it is not confined to these areas, and aesthetic issues apply in a wider range of domains. It is also important to note that beauty need not simply refer to pleasingness to the senses. Rather, as Immanuel Kant argued, the ultimate beauty is found in truth and order, regardless of domain. This means that aesthetic concepts can also be applied in areas such as science, engineering, business, or administration, which are aesthetically pleasing in the Kantian sense when they reveal truth and order.

Aesthetics and Creativity

There is a considerable overlap between aesthetics and creativity. Indeed, in everyday discussions creativity is often treated as almost synonymous with beauty, and thus aesthetics, although scholarly definitions give more emphasis to novelty and effectiveness. This close link between creativity and aesthetics is seen not only in art, but also in nonartistic domains. An example is problem-solving, a core topic in discussions of creativity: Li Zuo, for instance, concluded that creative problem solving involves finding *beautiful* problems and *beautiful* solutions, which requires 'aesthetic sensibility.' On the basis of case studies of well-known creative individuals such as Alfred Einstein and Charles Darwin, Zuo argued that it is aesthetic considerations that guide creative problem solvers to a solution; the nascent solution is so beautiful that their 'aesthetic awareness' tells them that it must be right. To take another example, Sandra Kay concluded that creative people are driven to move from less beautiful to more beautiful understandings of the world, not just from less accurate or effective to more accurate and effective ones, that is, 'aesthetic sensibility' is a major motivating factor

in creativity. Thus, aesthetics offers an extension of the way in which issues such as intuition/incubation or intrinsic motivation are looked at in creativity theory.

It seems that creativity is, in a certain sense, a special case of aesthetics: beauty is necessary for creativity, but not everything that is beautiful is creative. Creativity goes beyond 'mere' beauty to include novelty and effectiveness. It is worth noting here that the beauty of a creative product need not involve socially desirable or morally admirable purposes or results – creativity may lead to undesirable or immoral results, but still be beautiful in the Kantian sense.

Very early in modern discussions Mel Rhodes suggested studying creativity in terms of 4 Ps: person, process, product, and press, and aesthetics can be looked at in this way too. It is possible, for instance, to speak of an aesthetic person, aesthetic faculties, aesthetic feelings, aesthetic attitudes and values, or an aesthetic response. The aesthetic person is particularly sensitive to beauty (aesthetic sensibility), and aesthetic feelings involve attitudes and emotions that are aroused by contact with beauty. The aesthetic faculties are the sensory and cognitive processes that enable a person to perceive and distinguish among stimuli and thus have the potential to experience beauty, and a person's aesthetic sense makes it possible to recognize beauty in perceived stimuli; an aesthetic response involves responding to a stimulus in terms of its beauty, not for instance its usefulness or price. Experimental aesthetics investigates properties of the person which are related to aesthetic attitudes and values (e.g., preference for symmetry/asymmetry, sense of color, or openness to novelty), of processes (e.g., differentiated perception of stimuli, use of aesthetic schemata in making judgments), and of products (e.g., compositional geometry of an artwork, elegance of an object or system). Research in aesthetics on the fourth P (press) involves issues such as the effects of education or training on aesthetic faculties, aesthetic sense, aesthetic attitudes and values, aesthetic awareness, aesthetic sensibility, or aesthetic judgments.

Aesthetic Judgments

The making of aesthetic judgments is a process based on beauty rather than on logic or similar considerations. The perceptionist view is that such judgments are directly determined by the properties of an object, event or experience, which enter the brain as sensory stimuli. Thus, according to a pure perceptionist model a sound that hurt a listener's ears would be adjudged not beautiful, since it is an unpleasant sensation. James Mill extended this by arguing that it is the associations that a stimulus activates that cause it to be judged pleasing or displeasing. In any case, the aesthetic properties of a stimulus are regarded as inherent in the stimulus itself.

The contrasting view to perceptionism is the cognitive argument that aesthetic judgments are a construction in the mind of the beholder. Certain properties activate previously learned aesthetics-related cognitive schemata stored in the mind of the beholder, and an object or experience is classified and evaluated according to these schemata. The beholder thus infers that something is aesthetically pleasing or displeasing on the basis of acquired categories of pleasingness/displeasingness. To take an example, the cognitive approach argues that an intrinsically unpleasant sound such as atonal music might not be regarded as ugly but as beautiful by a beholder who had learned that this particular sound is beautiful, for instance through training and experience in a particular culture at a particular time, let us say by studying music.

The cognitive schemata according to which aesthetic judgments are made contain the stored results of the beholder's earlier experience and training, and are thus dependent upon the particular experience of the individual (i.e., they are subjective) as well as upon what the society has taught the individual is aesthetically pleasing or displeasing through formal training or life experience in the culture or a combination of both (i.e., they are relativistic). This suggests, among other things, that expert observers may judge an object differently from inexperienced ones, for instance because the experts have been trained to see beauty in objects the inexperienced typically find ugly or repulsive, or to recognize and focus on aspects of objects that are not apparent to untrained observers such as transformation of traditional materials or accordance with a particular school or style. An example is Andres Serrano's 'Piss Christ' which consists of a crucifix submerged in a glass of the artist's own urine. Many laypeople might find this disgusting, some experts by contrast found it daring, paradigm-breaking and highly effective, and it won a visual arts award from the Southern Center for Contemporary Art.

There is evidence that the level of agreement on aesthetic judgments among beholders increases with age, apparently as the result of a movement toward increased use of cognitive judgments with increasing cognitive maturity (as against reacting directly to the raw sensory stimulus, as a small child would) and of the homogenization of people's cognitive schemata that results from shared experience during long years of living in the same environment.

A second issue is whether aesthetic judgments are a cognitive reaction or whether they are emotional (affective) in nature. Do beholders judge beauty on the basis of

information processed according to internal cognitive guidelines, or because of the way something makes them feel? In the former case an object would be judged positively if it were, let us say, well-constructed. In the latter case it would be judged aesthetically pleasing if it made the observer feel good, displeasing if it made the beholder feel bad.

Aesthetic Products

An aesthetic product excites admiration in the mind of a beholder. The qualities that produce the admiration can be purely aesthetic such as 'exquisiteness,' 'gloriousness,' or 'gracefulness,' but they may also be formalist (e.g., 'unity,' 'harmony,' or 'complexity'), or technical (e.g., 'high quality of construction,' 'skillfulness,' or 'professional finish'). These qualities can be closed in the sense that they are narrowly defined, or open (a wide variety of states might, for instance, elicit the aesthetic judgment 'exciting,' according to the point of view of the particular beholder). However, as the eighteenth century philosopher Frances Hutcheson wrote, aesthetic qualities involve a 'subjective fact,' not an 'objective' one. This refers back to two general problems in the area of aesthetics and creativity already mentioned above: subjectivity (aesthetic judgments depend upon the person making the judgment) and relativity (the judgments differ from society to society and even from age to age in a particular society as the society's norms change). In early nineteenth century England, for instance, the language in the works of Shakespeare was considered unaesthetic, and in 1818 Dr Thomas Bowdler published the *Family Shakespeare*, from which all offensive words had been removed. To modern tastes this seems almost sacrilegious.

In the light of the subjectivity and relativity of judgments of the aesthetic qualities of any particular object (i.e., what is beautiful for one beholder may be ugly for another, while judgments may vary across cultures and/or change over time), psychologists have attempted to work out how to make absolute aesthetic judgments, on which different observers agree and which are stable both geographically and temporally. This has largely involved psychological tests investigating either what characteristics of beholders themselves lead to their judgments (such as good taste, preference for complexity/simplicity, tolerance for ambiguity, or openness to the novel), or what characteristics of the object invoke positive aesthetic judgments (such as unity, elegance, order, symmetry, or good finish). Such instruments include the Aesthetic Judgment Ability Scale, the Barron-Welsh Art Scale, the Maier-Seashore Art Judgment Test, the Maitland Graves Design Judgment Test, and the Welsh Figure-Preference Test.

Form Versus Function in Aesthetics

Emphasis on beauty as the core of aesthetics raises the question of whether beauty alone is enough. The view that it is was stated very strongly by the nineteenth century French novelist, Theophile Gautier, who argued in the preface to his novel *Mademoiselle de Maupin* that nothing is truly beautiful unless it is useless. However, the philosopher Ludwig Wittgenstein

argued that, in real life, terms like 'right,' 'correct,' and 'precise,' that is, terms closer to the domain of practical usefulness than that of artistic beauty, are more likely to be used as aesthetic praise than 'beautiful.'

This raises the issue of beauty of form versus function in aesthetics. We have argued elsewhere that artistic creativity is a special variant of creativity because in artistic creativity form takes precedence over function (i.e., beauty on its own is sufficient), whereas in engineering and similar domains the position is reversed: It is difficult to imagine a bridge being aesthetically acclaimed if it were built at great cost to carry traffic across a river but turned out to be useless because of design flaws, even though it looked very beautiful. Thus, there is a tension between exquisiteness of form (a pure aesthetic criterion of beauty) and correctness of function (a technical criterion), although the two are not mutually exclusive; an object may be beautiful in both form and function. Nonetheless, the two may have differing priorities in different domains: Form dominates in fine art, function in engineering, manufacturing, business, and similar fields. Architecture seems to occupy an intermediate position as far as the balance of beauty and usefulness is concerned. The Sydney Opera House cannot carry out the function that those who commissioned and paid for it envisaged (the staging of large-scale opera productions before very large audiences). However, because the Opera House's form is beautiful this flaw is forgiven and, indeed, the structure has become an Australian icon.

Creative Products

A product's creativity is not objective like length or weight, which can be measured accurately with appropriate instruments and mean the same even when applied to different objects, but, like aesthetics, is a 'subjective fact' (see above) and is thus affected by subjectivity and relativity. Early in the modern creativity era Teresa Amabile, and later Mihalyi Csikszentmihalyi made this plain when they argued that 'socio-cultural validation' is needed for creativity – a product is creative when experts in a domain apply the term to it in order to express their approval, and judge that it is suitable to be incorporated into the field in which they are experts. In other words, the creativity of a product is in the eye of the beholder and is relative to what the society judges to be suitable for a particular field. Furthermore, as for instance Kay and Zuo pointed out, experts' judgments are affected by aesthetic awareness, which is at least in part learned and peculiar to a particular culture.

Creativity theory has long acknowledged that there is a difference between creativity in the sense of a novel work that is revered over the ages and in the sense of simple production of variability that is quickly forgotten, even if its novelty is effective in a particular context at a certain moment. A homely example of the latter would be the creativity of a home cook who made an unusual combination of ingredients to produce a new and pleasing taste effect which was praised at the time but was not recorded and was only vaguely remembered, even by the cook. One way of referring to these two kinds of creativity has been to label them 'little c' and 'big C' creativity. A related issue involves the question of the difference between children's creativity, especially young children, and that of

adults. Both groups may display divergent thinking, high levels of motivation, openness, ability to use certain tools (such as crayons), risk taking and similar processes and properties, and yet there are marked differences between what they produce. The application of concepts from aesthetics provides a way of describing the similarities and differences: the work of children may well display aesthetic sensibility, aesthetic awareness or aesthetic feelings, but it seldom leads to products that strike beholders as beautiful or as revealing truths about the world or delivering insights into the structure of things.

Useful Products

The problem that creativity is essentially an aesthetic judgment based on the subjective views of observers and the current tastes of the society has dogged creativity research from early in the modern era. Some writers such as Robert Albert have argued that defining the creativity of products is too subjective and too unstable (relative), and recommended concentrating instead on creative people and creative processes. However, early in the modern era David MacKinnon and more recently Susan Bailin have insisted that products are the 'bed-rock' of creativity, and are central to its study. Thus, what is needed is a systematic way of understanding what the properties of products are that make them pleasing to observers and lead to aesthetic judgments that different people agree on and that are stable across societies and over time.

It is notable that most discussions of aesthetics have involved fine art. Questions of the aesthetic properties of, let us say, engineering products, business solutions, manufacturing systems, or administrative procedures are far less frequently studied, although not entirely ignored. That aesthetic properties of such products are evident to observers was attested to by the rocket engineer Wernher von Braun, who stated that: "The eye is a fine architect. Believe it!" He meant that they are pleasing to the eye, and that this supports the inclusion of beauty, along with effectiveness and novelty, as a key criterion of creativity. In recent years, discussions of, for instance, engineering design have been broadened to give greater emphasis to aesthetic issues, and this broadening of view has been reflected in some official documents such as curriculum materials for technological design education.

The idea of functional (useful) novel products is probably most obvious when it is applied to daily-use objects such as an appliance or machine, or to an effective, complex system of some kind (such as a jet aircraft, or a business information system), or on the other hand to a process in the sense of a service, technique or method (a manufacturing process, a control process, a logistics service). However, paintings, musical compositions, poems or novels, or even systems of ideas as in, let us say, philosophy or mathematics, are also products that successfully perform tasks of their own kind, such as capturing the essence of beauty or order, or communicating a feeling to another person, or introducing a new way of going about tasks of this kind.

The question now arises: "Useful to whom?" In the Renaissance, the notion of *il divino artista*, who is above the rules that apply to other humans was widely accepted, for example, Benvenuto Cellini. Later, the same view received a powerful

boost during the heyday of romanticism, and was exemplified by such outstanding (but morally flawed) creators as Lord Byron and Richard Wagner. In related, more recent psychological discussions, creativity has frequently been looked at in an extremely individualistic way, and has been regarded as closely connected with self-actualization. Not infrequently, this self-actualization has been seen as requiring a fight against the surrounding society or 'defying the crowd.' Contrasting with this emphasis on the individual, however, is the idea that creativity should be useful to the society. In seventeenth century Europe, Francis Bacon and René Descartes, two leaders of the enlightenment, wrote that the main purpose of scientific creativity was to serve the common good. Robert Sternberg argued that creative products must be guided by wisdom and that wisdom necessarily involves striving for the common good. This raises the question of whether something destructive or evil can be regarded as aesthetically pleasing.

A Universal Aesthetic of Creativity

More than 250 years ago, William Hogarth attempted to develop a universal set of aesthetic criteria for judging the beauty of artistic products, and concluded that there are six central qualities: (1) harmony among the parts of a work; (2) variety in as many ways as possible; (3) uniformity, regularity or symmetry, which is only beautiful when it helps to preserve the harmony in (1); (4) simplicity or distinctness, which gives pleasure not in itself but by enabling a beholder to enjoy the work's variety; (5) intricacy, which makes it necessary for the beholder to think actively about the work; and (6) quantity or magnitude, which captures beholders' attention and produces admiration and awe. More recently, however, in a famous and frequently cited essay in the area of art criticism, Clement Greenberg argued that "each art form has its own system for the judgment of aesthetics." This issue of domain specificity versus generality has been discussed in a more general way by various writers such as John Baer and Jonathan Plucker. Arnold Ludwig showed that there are both similarities and differences across domains, largely deriving from the cognitive (relevant skills and knowledge), motivational (e.g., determination vs. inspiration), personal (e.g., openness for the new vs. application of the familiar) and other demands of the domain.

In the preface to his own novel, *Nigger of the Narcissus*, Josef Conrad suggested a taxonomy for distinguishing different forms of creativity that implies that aesthetics only applies to artistic creativity: He argued that writers, poets, artists and the like achieve creativity through production of *beautiful* objects, whereas philosophers do it through production of novel ideas, and scientists and engineers through production of novel facts. Indeed, aesthetic judgments based on beauty of form are typically regarded as applying mainly to fine art, literature, music, drama, dance, and similar artistic fields. However, recent discussions such as that of David Cropley, James Kaufman, and Arthur Cropley have asked whether a universal aesthetic can be developed which is capable of being applied to products in all domains, including not only fine art, music, or literature, but also science, medicine, engineering, and technology, or business and manufacturing.

Jerome Bruner gave some idea of what usefulness would involve by emphasizing 'relevance' and 'effectiveness,' and more recent writers have stated that products must be appropriate, correct, useful, or valuable. In other places we have argued that, although novelty seems intuitively to take precedence over usefulness in determining creativity, in the practical world the most important aspect of a useful product that excites admiration in the beholder is effectiveness. A product must be valuable, logical, useful, and understandable. To take a simple example, a bridge must get traffic across a river. If it does not do what the engineers were hired to build it for, it lacks effectiveness and is thus not creative, no matter how novel it is.

Even in artistic domains, effectiveness is important. Emile Zola displayed extraordinary imagination and poetic fantasy (novelty) in his novels, it is true, but without his mastery of the French language, painstaking research, and detailed drafting of plot his manuscripts may well have been surprising, even shocking, but would have lacked effectiveness and may well have produced no more than quasicreativity. Vincent Van Gogh lacked technical knowledge of how to paint, and had to return at the age of 32 to the Academy of Art in Antwerp, where he was taught to express his flair for color and light in an effective way. He did not have to learn how to generate novelty, but how to convey it effectively to others.

However, Einstein made a direct link between creativity and aesthetics by arguing that it is not difficult to find novel solutions to problems that achieve the desired effect. The difficult part is finding solutions that are beautiful (that is, aesthetically pleasing). Robert Grudin reinforced this idea when he referred to "the *grace* of great things [emphasis added]." These authors were, in fact referring to the beauty of products, that is, to their aesthetic properties. Aesthetically pleasing solutions are logical, harmonious, organic, and complex (labeled 'internal elegance' by Cropley et al.) as well as well-crafted, pleasing to observers, even beautiful (external elegance). Elegance thus involves a mixture of pure aesthetic, formalist, and technical properties. Such solutions not infrequently cause a more or less instantaneous shock of recognition when they occur, and provoke a "Why didn't I think of that?" reaction. Indeed, an elegant solution may look so simple and obvious – after the fact – that viewers may under-rate its creativity or denigrate it as banal.

A second additional criterion of aesthetic pleasingness in creative products is 'Genesis.' Generic novelty is not only useful in the situation for which it was generated, but can also be applied in other apparently unrelated situations. It may introduce a new way of conceptualizing an area, for instance by opening up new approaches to existing problems (germinality), or by demonstrating the existence of previously unnoticed problems (seminality). In other words a generic product reveals the fundamental truth and structure of a domain, that is, it is beautiful in the Kantian sense.

Conclusion

Recognizing the aesthetic elements of creativity expands the vocabulary and concepts that are available for studying it, casting new light on issues such as creative problem solving or motivation in creative individuals. However, although the

label 'creative' involves an aesthetic judgment, the idea of beauty is both subjective and relative, with the result that it is difficult to obtain agreement among different beholders on aesthetic properties. This means that the judgments of experts such as, let us say, art critics or teachers may disagree markedly from those of laypersons or schoolchildren, with consequent difficulties of communication. For a similar reason, experts from differing aesthetic cultures may make widely differing aesthetic judgments. A universal aesthetic of creativity would enable not only teachers, critics, and reviewers, but also practitioners such as artists, scientists, or engineers to express in a cohesive and systematic way the effect on them of the different kinds of performance that they regard as creative, perhaps making it possible for people who generate creativity in different domains such as the arts, science, fashion, design, architecture, engineering, manufacturing, and marketing to articulate in a common language (to themselves, to colleagues, to critics, to sponsors, to clients, to the general public, etc.) what they are seeking to do, or have done. It might even make it possible to compare, let us say, the Mona Lisa, directly with the Golden Gate Bridge, Einstein's theories of relativity, or an advertising campaign. We have suggested such a system by adding aesthetic criteria (elegance and genesis) to novelty and effectiveness in defining creativity.

Aging

I M Carlsson and G J W Smith, Lund University, Lund, Sweden

© 2011 Elsevier Inc. All rights reserved.

Introduction

In the year 2009 the artist Louise Bourgeois was 98 years old, a fact which added a special flavor to the media's reports about her, at least from a Swedish perspective. In one newspaper, for example, it was claimed quite a tragedy for Bourgeois as a human being, that she was still seeking her identity.

Another likewise illustrative example is the scientist Jan-Åke Gustafsson, who had said that he was expecting to quit his career in Sweden, upon turning 67 the following year. Instead he described how he had been welcomed to Houston, Texas, where he was fully engaged in the building of a large research center, planned to house 150–200 researchers.

Society's regulations, for example, mandatory retiring at a certain age, inevitably influence people's attitudes in general, and researchers are no exception. The scientific view on how getting older affects us, as far as creativity is concerned, has been a matter of dispute for more than half a century – boiling down to the key question whether we, as some believe, become less creative with age, and in some instances, wiser. Others assert that it is possible and indeed good for you to keep your creativity alive, and that it actually helps you to stay happy and 'alive and kicking' as senior citizens. For example, people with higher scores on a creativity measure have been found to have a more positive attitude toward aging compared to those with a low score.

The Definition of Creativity

This brings up the issue of how we define creativity. As is often the case, part of the answer depends on the perspective. Focusing on the creative product, we might on the one hand concentrate on major and long-lasting ('big C') contributions made by a person in their chosen field, or we could discuss 'little c,' implying contributions on a small scale to a person's well-being and to their near environment in time and space. Since obviously the large majority of people have not contributed on a grand scale to the culture or to our society, the present article would only concern a small minority, were we to restrict ourselves to the 'big C.' Instead we prefer to touch upon a slightly philosophical note, or at least an evolutionary one, where we agree with earlier scientists, for example, Lev Vygotskij, that every human being is equipped with a potential for creativity. This claim does not exclude that we fully understand and likewise adhere to another principle, namely that the individual's resources in a wider sense, ranging from individual differences to the environment in terms of family and society, exert positive or negative influences on the scope as well as the fulfilment of a person's creative potential.

Creativity, as we see it, should primarily be defined by the novelty of the products, not by the usefulness, value, or beauty. It is rather that the new product or idea has been developed in

dialogue with the reality it is intended to replace. Creativity is not an inherently good thing in the moral sense, but is used in the interests of a certain individual or group.

The Life Span Developmental Model of Creativity

Considering this definition, we think it is important to widen our search from the product perspective to other perspectives when we look for new research about creativity and aging. In the first edition of the *Encyclopedia of Creativity*, Becca Levy and Ellen Langer made a valuable summing-up of the controversy between the so-called Peak and Decline view on the one hand and the Life Span Developmental Model on the other. The decline model was formulated by Herbert Lehman in the middle of the last century. His view has had a long influence, as was thoroughly described and discussed by psychologist Martin Lindauer, in his book *Aging, Creativity, and Art*. According to Lindauer, the quantitative measurements of creative historical persons, that were done by Lehman, have had a major influence over our views on old age creativity. However, in agreement with Levy and Langer, Lindauer concluded that despite its advantages, the decline model has many deficiencies due to both methodological and conceptual difficulties, with regard to the creativity concept as well as the conception of aging. Instead Lindauer showed good arguments for the continuity (life-span development) model, or rather that creativity is manifested differently over the lifetime due to the different demands on younger and older individuals. The many creative accomplishments of very old and very famous artists are important counterarguments to the early decline model and to the ageism which exists in society.

Additional support of the life-span development model was earlier found by the authors. In one project we investigated children's creativity in cross-sectional the age groups. Here we found lows and highs depending on age group. In seven year olds, creativity was particularly low, possibly due to both developmental factors and to the fact that these children had recently begun regular school (which in those days was the year when the child reached seven years old) and were still in the process of adapting to school. This result makes it quite likely that there exists a more accurate model than the linear one for how creativity develops over the life span.

In another study creativity levels were compared between a youngsters' group, a group of middle-aged people, and an elderly group including both recently retired persons and older pensioners. Creativity, as measured in the testing, was present in around two-thirds of the youngsters' group. It was found in half of the middle-aged group of people, and a few percent below that in the retired group. One thing contributing to the relatively modest level of creativity in the middle-aged persons' group could be that these years are pretty stressful, occupied by several duties that draw from the resources

available to function creatively. In this comparison of several age groups it is noteworthy that rather many pensioners had signs of creativity when tested, although admittedly most were on the lower end of the scale. It is probable that this group, born during the first two decades in the previous century, had had scant acquaintance with research and psychologists' tests, as well as having undergone a more authoritarian upbringing. These circumstances may have contributed to their greater cautiousness and their need to perform correctly and adhere to the objective norm.

An important scholar we find relevant to mention in this connection is psychoanalyst George Vaillant. He has underlined the mysterious fact that creative old people are still able to play. He continued by discussing the intriguing psychodynamics involved in creativity as an adaptive ego operation, and that it is also an ego function beside conflict. Vaillant's standpoint was that we all have the capacity for creativity within us. But since he also claimed that the task of youth is to innovate and that the task of old age is to pass on what has been learnt, in his conclusions he implicitly seems more supportive of the Peak and Decline model – as indeed was Freud before him. One argument in response to Vaillant is that it takes creativity to be able to pass on what has been learnt, for example, when relating to younger generations or writing about one's life and acquired knowledge – in line with Lindauer's discussion about different demands on the creativity of younger and older individuals.

New Conceptions of the Brain and of Creativity in the Latter Part of Life

"Becoming very old is good – as long as I don't have to take the consequences!" Whether this is a real quote from Woody Allen or not, many of us probably agree with the sentiment. People seek longevity but want to keep their vital functions intact. For example: After a certain age, in the late summers you start to listen eagerly for crickets and you get very relieved when you hear one. Let us then hope that you have not mistaken your tinnitus for the crickets!

Indeed we cannot escape the fact that physical functions and vital organs in the body get worn and lose the capacity of the young. For instance our pulse maximum decreases when we get older and it cannot be improved by training. Another example is that older adults have more difficulty focusing their attention and ignoring distracting stimuli. Much decline in mental ability is however often not caused by aging *per se* but by specific diseases, such as dementia or depression.

A notable contribution in support of old age creativity was recently made by psychiatrist Gene Cohen. Acknowledging the great contribution regarding the general life span development made by Erik Homburger Erikson, Cohen stated that Erikson himself thought his work on aging was incomplete. Cohen therefore delineated a new model of psychological development in the latter part of life, to be described below in certain detail.

Building on new research findings about the brain, Cohen made some important statements about it: First that the brain continues to develop into old age due to new experiences and learning, and that actually new brain cells form in the adult

brain. Next, that the brain's biological basis for our emotional life also develops and gets more balanced with age; and finally that the brains' two hemispheres are more equally used by older adults.

It is of interest that older people in certain tasks use the two brain hemispheres more equally, which according to Cohen could contribute to make old people more creative. This has however in other research also been interpreted as a sign of compensation for loss of resources which leads to the activation of larger brain areas.

Empirical support for the importance of using both hemispheres for creativity has earlier been given in research showing that highly creative young adults used both their frontal lobes approximately equally during a creativity task, in contrast to low creative persons who mainly activated areas in their left frontal lobe. However, since we know of no study that has actually looked at the hemispheric activity when old people perform a creative task, Cohen's point needs more evidence. Recent brain research clearly speaks in favor of the preservation of old people's cognitive and relational competences, but it is uncertain if this fact implies creativity, or if it rather leads to better and wiser decisions in older persons.

It is an indisputable fact that it takes many years of hard work and experience to achieve excellence in a field, and the reported difficulties with distracting stimuli might actually simultaneously be an indication of creativity, since research has shown that creative persons are often typified by slight disinhibition in the brain. It seems likely that disinhibition in the brain is one of the ingredients in human curiosity. Being less inhibited and controlled sets loose our inquisitive and curious minds, and the urge to seek out new problems and unanswered questions is an obvious starting point and motivating force for creativity. A curious mind is an important ingredient in what Cohen calls the Inner Push – the fundamental need to grow and develop.

Four Developmental Subphases in the Mature Age

Regarding the development in later adulthood, Cohen formulated four different subphases in what Eriksson called the mature age, namely midlife reevaluation, liberation, summing up, and encore. In the *midlife reevaluation* phase which encompasses the forties and fifties, people come closer to the personal realization that they themselves will die. They do not any more have only the abstract thought that people eventually will pass away. This brings forth a sense of a quest, or in some instances, crises where new exploration is made and maybe a transition to new fields. Certain positive new qualities follow from this reevaluation, for instance more openness to new ideas or complexity in life, as well as greater respect for one's intuitive feelings.

Secondly, *liberation* phase, roughly covering the time between the late fifties to early seventies, people have a sense of "if not now, when?" and coupled with partial or full retirement this gives the feeling of greater personal freedom to act according to one's own needs. Referring to empirical studies, Cohen claimed that this phase includes a significant shift in personal identity and furthermore that the brain in this age period has the richest number and density of dendrites in the

hippocampus – the brain's 'memory centre' – and that new neurons form as well in the hippocampus. In combination, this gives both the push and the capacity to learn new skills and enter new challenges.

Interestingly, recent research has shown – albeit on laboratory rats – that lifelong intermittent environmental enrichment since infancy prevents the decline of recognition memory, reduces anxious behavior in a novel environment, and increases the number of newly generated neurons within the hippocampus during aging. Obviously, a mouse is not a man, but nevertheless the species share many biological characteristics, making the generalization quite feasible.

Cohen describes the third phase as the *summing up*, which we enter when approaching seventy, or sometimes several years later or earlier. Typically, people now need to find an overall meaning in their lives, and to pass on to others their accumulated knowledge and other resources. This can be accomplished by personal story-telling or even memoirs. Moreover this phase implies new pressures to look back and review one's life and, if possible, to bring closure to unfulfilled business – whether with other people or with important projects.

The last part in our lives, from the late seventies and onward, the *encore* phase in life, is a set of variations on a person's life themes, and the three preceding stages are now combined, motivating the person to sometimes engage in 'jumping the tracks,' according to Cohen. Even despite serious physical problems an old person can feel vitality and enjoyment, especially in close and significant relationships. To learn new things and to train your brain, are according to Cohen, the keys to vigor in the oldest age groups.

All the good advice given by Cohen to older people cannot possibly be recapitulated here, but we could not abstain from sharing his advice about keeping a dream journal. To be able to remember our dreams at night, as it seems, becomes less frequent with age – even if we can only present anecdotal support for this belief. We are inclined to agree with Cohen's assertion that dreams are sometimes creative. His own example of awakening from a dream is quite fascinating: He describes how he was dreaming a creativity equation formulated as: $c = me^2$, and interpreted it such that our creativity (c) equals our mass (m) of knowledge, multiplied by the effects of our experience (inner psychological combined with outer life experiences; e^2). Obviously, as he himself acknowledged, the equation is wish-fulfilling, and supports his thesis, namely that when we get more knowledge and experience we also get the resources to become more creative!

The Creative Person's Contact with the Inner Child

The authors must however point out that the matter is not settled there, and that Cohen's creativity equation needs further interpretation. Not just knowledge and experience are needed for us to be creative. Rather, much motivating power must be provided to serve as the necessary ignition fuel, to more or less keep the engine constantly working, to keep us daring and venturing to take risks against the odds. Looking in the rear view, it seems that when certain important aspects in our lives are fulfilled, maybe the drive, or inner push in

Cohen's words, tends to get weaker. We are convinced that the significance of the whole word '*me*' in the playful equation above should be considered as the most important factor!

Personality variables have been described by many scholars to play a decisive role for the creative accomplishments of a person, indeed more so than general intelligence above a certain level. High sensitivity and elevated anxiety levels have been recurrent in our own findings, together with a flexible defensive structure. This flexibility includes both childish as well as mature defensive signs, and moreover very often includes an ability to symbolically or metaphorically handle and elaborate on a disturbing reality.

It would seem that a child with both high sensitivity and high curiosity could be the parent of a creative veteran, so to speak. Early stressful life experiences are often harder to bear for a sensitive child but serve at the same time as fuel for his or her motivation. Difficult life events, given the proper environmental support and resources, can be the necessary fuel for the first creative accomplishments which from thereafter enforce and encourage further efforts in the same vein.

It is probably productive to start 'exercising' creativity from early childhood. Even if a curious mouse is not really creative, the enriched environment proved to have good effects for cognition and feeling in the old mice. For infant human beings as well, more varied environmental stimulation and opportunities to explore it freely, may have long-lasting effects on the later life. Studies have found that creative old people often put up less blocks against (experimental) threats of illness, and also have a more flexible and emotional view of themselves. If the individual learns early on to develop and use flexibility and imagination, this should give better possibilities to overcome obstacles and drawbacks during the life, and most probably a healthier life than if creativity was stifled.

A System's Perspective on Creativity

When viewing creativity over the life span, it is wise to broaden the perspective, as for example, done by Mihalyi Csikszentmihalyi, from the individual to the environment, and not least to the individual environment at their work. Since a large part of our time before we retire is spent at the workplace, to spread the present conditions existing at many workplaces should give opportunities for the seniors in society to keep their engagement high. This ought to be a benefit for various things, not just keeping the direct costs lower for illnesses and disease.

It seems to be never too late, if Cohen and Landauer are correct, to start practising your imaginative mind and begin looking in new directions. After a strained working life it appears to be a fact that people tend to feel several years younger after having retired. This of course is quite understandable but also says something less fortunate about the increasingly pressing conditions and conflicting demands at our workplaces. Too much emphasis on high productivity and maximization of growth is likely to cause a general decrease in the staff of precisely the thing that is sought after, namely the truly creative persons bringing forth high innovation.

If creativity depends on different resources from the environment as well as from the individual, then it would seem quite inevitable that when retiring from work people lose

many outer resources needed to continue their professional creative endeavor. However, given that the inner push still is there, the person may continue to explore and be curious, sometimes in other domains. Maybe the creativity changes from a 'big C' into creativity on a smaller scale, or, in fact, the opposite can occur too. The 'courage to create,' as it was once formulated by Rollo May, should be greater in the older age groups, since much has already been accomplished, and you have become more confident in your own ability to create. According to Csikszentmihalyi, creative wisdom needs a broader viewpoint and the combination of knowing and sensing, feeling and judging. Naturally, this often cannot be expected to bring public success, but instead deeply personal meaningfulness and connectedness to mankind and one's existence.

Conclusions

The creativity of older people, coupled with their wisdom, appears to be a much needed competence. In today's highly technological world, new ideas, paired with not yet developed wisdom in youthful 'folly,' can lead to immensely more fatal, as well as far-reaching, consequences than could ever have happened in man's evolutionary childhood. However, this fear that the young are too wild seems to have been in existence since ancient times – naturally we can do nothing else but to set our hope on the young who the world is bound to rely on.

Encounters between the young and the old are often lacking but are immensely important. Since creative people even in old age tend to view themselves as younger than their actual ages and to have access to the inner child, schools, for example, should seek help of older volunteers to a much greater extent than is currently the case. The old age groups are growing faster in numbers than the younger ones – at least in the European and North American societies – making it of plain socio-economic importance that stereotypical attitudes and ageism are diminished in the general view on aging, which otherwise will continue to generate self-fulfilling prophecies and perpetuate discrimination.

It is our belief that being creative is to be alive in a deeper sense of the word, and that it implies 'open doors' exist both toward the external world and to our own inner world. If the door to one's own deeper layers is bolted in denial, this may lead to blocks or to a manic proficiency, but not to really creative solutions to the challenges we meet at each new step in life. From a dynamic perspective it is acknowledged that the inner 'memory cosmos' developed during an individual's lifespan is for the large part unattainable. Still, important memories from the early years continue to color and ignite feelings and meaningfulness in latter years.

Each crucial occasion in the life of an individual involves actualization of past, often hidden experiences. As many can bear witness about, creative channels help us to cope and transcend losses. These inevitable losses may even trigger a creative response and the use of latent resources. To seek one's identity repeatedly in a creative process during the lifetime implies confronting deeply personal questions carried along from the early years. In essence these are questions about relationship versus separation, and failure versus mastery, and the final existential question about how to master the separation.

Altered and Transitional States

This article is a revision of the previous edition article by Stanley Krippner, volume 1, pp. 59–71, © 1999, Elsevier Inc.

Glossary

Altered states of consciousness An 'altered' conscious state can be defined as a pattern of phenomenological properties recognizable by an individual (or group), or by an external observer of that individual (or group), as representing a major difference in behavior and experience from an ordinary baseline pattern of waking consciousness. An 'altered state' involves changes in a number of those phenomenological properties such as emotions, intentions, perceptions, imagery, and other so-called 'subsystems' of consciousness. Both dreaming and nondreaming sleep differ from baseline consciousness, thus qualifying as 'altered states'; so do variants in wakefulness resulting from meditation, prayer, mediumistic activity, 'peak experiences' in nature, and other 'spiritual' experiences. Studying the phenomenology (or subjective experience) of an 'altered state' can be accomplished through observation, self-reports, interviews, or administration of such instruments as the Pekala scales.

Changes in consciousness Changes in patterns of phenomenological properties can be brought about by contemplative, sexual, athletic, recreational, and other pleasant behaviors as well as by unpleasant ordeals such as torture, starvation, and trauma, or alleged 'possession' by discarnate entities. Psychopathology provides additional examples, such as dissociative and mood disorders,

post-traumatic stress reactions, and psychotic episodes. Both pharmaceutical drugs and psychoactive plants may produce changes in one's phenomenology.

Consciousness The term 'consciousness' derives from the Latin *conscire*, to know with, or to be cognizant of something. Ordinary waking consciousness reflects the explicit knowledge of one's situation, along with such patterns of phenomenological properties as awareness, attention, intentionality, and one's sense of personal existence. In general, 'consciousness' can be described as a pattern of phenomenological properties (perceptions, cognitions, feelings, etc.) that characterize a human or other sentient organism at any given point in time.

Creative The term 'creative' can be applied to any act, idea, or product that changes or transforms an existing domain. A phenomenon is creative if it is novel and, in some manner, useful or appropriate for the situation in which it occurs.

Transitional states of consciousness Typically, a 'transitional conscious state' lasts for a brief period of time, mediating between two longer lasting patterns of phenomenological properties. Hypnagogic states are transitional because they mark the shift between a baseline state (wakefulness) and a long-lasting altered state (sleep). Other transitional states include daydreaming, reverie, napping, and hypnopompic states, the latter occurring when a person is awakening.

Creativity, Consciousness, and Culture

The terms by which people make sense of their world are social artifacts, products of historically situated interchanges among people. In the history of Western civilization, not all individuals have had equal opportunities for creative expression. For example, the creativity of women was rarely valued or encouraged; they were given few occasions to develop the skills (e.g., critical thinking) or life circumstances (e.g., solitude) on which creative work often depends.

Historical Overview

The paintings in the Lascaux Caves of southern France date back at least 17 000 years; the prone figure depicted there is often regarded as a shaman experiencing a changed state of consciousness. Because psychedelic (from the Greek words *psyche* and *deloun*, i.e., 'mind-manifesting') substances helped many shamans enter the 'spirit world,' they became a technology for the production of mythic narratives, theatrical performances, chants, songs, dances, and other products currently labeled creative. Traditional Siberian shamans still 'journey' to

the 'spirit world' with the aid of psychedelic mushrooms and/or rhythmic drumming.

Initiates of the Eleusinian Mysteries in ancient Greece probably used a potion containing a psychedelic fungus to fathom what the poet Pindar called "the end of life and its god-sent beginning." India's Vedic hymns sing the praises of *soma*, an intoxicant that was "all pervading, swift as thought"; psychedelic mushrooms may have been its active ingredient. In pre-Conquest Mesoamerica, the natives used their talents creatively in the service of their religious beliefs. Aztec poets and musicians rhapsodized about the 'dream flowers' that took them to another world. Wasson, writing in 1980, found similarities between the use of psychedelics in pre-Conquest Mexico and their use in ancient Greece; mind-altering plants adorn both the vases of Attica and the architecture of Mitla.

Cross-Cultural Comparisons

Societies have an assortment of terms to describe activities resembling what Western psychologists refer to as creativity; for example, the first hexagram (or *kuan*) of the Chinese 'Book of Changes' (or *I Jing*) is *Ch'ien*, the 'Creative Principle.'

Most Asian, African, and Native American traditions also used creative imagination to enrich and enhance everyday life; novel, original contributions were typically seen as gifts from deities or spirits who used humans as 'channels'. Yet in some of these societies an individual who produced something unprecedented (e.g., an unusual mask) was censured for breaking with tradition; talented craftspeople were valued, but individuals with a flair for novelty were chastised. When the church's power was dominant, Western cultures tended to consider 'channeling' as demonic; once 'enlightened' science and medicine prevailed, such forms of experience were cast in psychopathological terms. By contrast, traditional Eastern cultures such as Hinduism and Buddhism had intricate vocabularies to describe the spiritual aspects of changes in consciousness. Many tribal people go through the day in what Westerners would consider a well-organized hallucination, since the world they believe and live in bears very little resemblance to the lived experience of Westerners. In dreams and in waking visions, the Maya people asked their deities to appear before them, reflecting a tradition of visionary ecstasy that had bequeathed them an intense and often overwhelming universe. Pre-conquest Maya artists depicted an overlap between the world of everyday reality and the 'spirit world,' suggesting a baseline state of consciousness that was much more 'dreamlike' than that of their European conquerors. Freud's description of the conscious ego as the external boundary of an invisible matrix of volatile 'psychic energies' that feeds and informs it resembles the shamanic energetic model of the human body embedded in a community and environmental matrix. However, from the shaman's perspective the 'unconscious energies' of the Freudians were not blind and irrational, but keenly intelligent, originating in the earth itself rather than in the neurons of the brain.

Creativity and Psychedelic Substances

Psychedelic substances and other drugs affect consciousness by modifying the process of synaptic transmission in the brain. Excitatory and inhibitory connections between neurons are carried out by transfer of special biochemicals (neurotransmitters) across the synaptic gap between neurons. Drugs can affect synaptic transmission in a variety of ways, such as blocking the production or reception of a neurotransmitter or mocking a neurotransmitter, thus effectively increasing its activity level. The phenomenological pattern that a drug evokes depends upon which particular neurotransmitters it affects and how. In the case of psychedelics, the result seems to be a disruption of logical analysis and the automatic reality-checking functions of the brain, probably connected to the ability of these drugs to block serotonin transmission. In psychotherapy, psychedelics can produce a depatterning influence that breaks up the individual's habitual experiences of the world, tending to increase the individual's suggestibility and susceptibility to reprogramming.

There have been several anecdotal accounts by creative individuals in Europe, Canada, and the United States claiming that their creative behavior has been positively affected by ingestion of psychedelics. They include neurologist S. Weir Mitchell, British writer Aldous Huxley, US naval technician John Busby, actors Cary Grant and Rita Moreno, and the

Canadian architect Kyo Izumi. Both Kary Mullis and Francis Crick attributed their Nobel Prize-winning discoveries (e.g., a deoxyribonucleic acid (DNA) detection method; the double helix structure of DNA) to experiences with D-lysergic acid diethylamide (LSD), at least in part.

The 'Model Psychosis' Assumption

Some early researchers reported that LSD users gave highly imaginative, although bizarre, responses to Rorschach inkblots. In summarizing his observations of LSD users in 1976, the psychoanalyst Silvano Arieti found that the use of 'primary process mechanisms' was enhanced, but that the 'secondary processing' required to put the imagery to creative use was impaired. These studies and related research, conducted with both artists and nonartists and with both laboratory subjects and 'street users,' identified many dysfunctional results of informal psychedelic drug usage but no conclusive data supporting the notion that psychedelics could produce a 'model psychosis.' In 1988, T. E. Oxman and colleagues reported a content analysis of 66 autobiographical accounts of schizophrenia, psychedelic drug experience, and mystical experience, as well as 28 autobiographical accounts of personal experiences in ordinary consciousness. Finding that 84% of the samples could be categorized correctly on the basis of word frequencies, they concluded that there is a 'clear dissimilarity' among changed states of consciousness, especially between psychosis and psychedelic drug states. This contradicts the 'model psychosis' perspective and its assumptions about congruences between schizophrenia and patterns of phenomenological properties evoked by such drugs as LSD, mescaline, and psilocybin. Creativity, of course, is only one of several instances of psychedelic phenomena, but one that often can accelerate the incubation phase of the creative process.

Creativity Research with Unselected Subjects

A number of studies were conducted with unselected subjects, primarily college students, in the 1960s and 1970s in an attempt to determine the relationship between psychedelics and creative behavior. For example, to study the effects of LSD on creativity test scores, a test battery (also administered to a control group) was given before LSD ingestion, and alternative forms of the same tests were administered 2 h afterwards. It was observed that most of the comparisons on the creativity tests favored the LSD group; on the other hand, that group did poorly on tests requiring visual attention. In another study, one-third of subjects were administered a high dose of LSD, one-third a low dose, and one-third an amphetamine. A test battery was administered to each group prior to drug ingestion and again at intervals of 2 weeks and 6 months after the third session. The low LSD and amphetamine groups obtained similar scores, but the high LSD group bought more musical records, spent more time in museums, and attended more musical events; neither LSD group demonstrated higher scores on creativity tests. Another study dispensed psilocybin to volunteers, most of whom were able to complete a creativity test and a test for brain damage before the session, as well as 90 and 270 min after drug ingestion. A significant inverse relationship between the scores on the two tests was reported.

These and similar studies cannot be considered conclusive, since they differed in many ways; however, it appears that volunteers cannot expect their creative behavior to be enhanced by psychedelic ingestion alone.

Creativity Research with Selected Subjects

In the 1960s, LSD was administered to 50 well-known artists at the Max Planck Institute in Munich. The results varied, but the artists concurred that the experience was of value, and the ensuing work was displayed in a Frankfurt gallery. In a study on the effects of mescaline and LSD on four US graphic artists, a panel of art critics judged the paintings to have greater aesthetic value than the artists' usual work, noting that the lines were bolder and the use of color more vivid. A similar study giving LSD to American actors, artists, musicians, and writers resulted in judgments by a professor of art history that the LSD paintings were more imaginative, especially in color, line, and texture, though the technique was poorer.

A study of professional workers in architecture, engineering, commercial art, furniture design, mathematics, and physics showed that mescaline ingestion resulted in a statistically significant increase in creativity test scores, with enhanced fluency of ideas, visualization, and field independence. Interview and questionnaire data suggested that about half the group had accomplished a great deal more during the mescaline session than would have characterized their ordinary workday. All subjects reported positive reactions to mescaline, but a larger number of subjects were unable to concentrate on their projects because they were diverted by the experience itself.

Cross-Cultural Considerations

The potent red mescal bean, *Sophora secundiflora*, has been found with the remains of the extinct bison and the tools and weapons of early North American hunters. Many of the chants and poems used in spiritual ceremonies make great demands on the practitioner; the Yakut shaman in Siberia, for one, has a poetic vocabulary of some 12 000 words for use in *Amanita muscaria* mushroom rites, as compared to 4000 in the ordinary language of the community. The Zuni rain priests of New Mexico have a special language with which they converse with spirit birds once they have ingested the mind-altering *Datura meteloides*. For native people, these substances are not taken trivially, for momentary pleasures or 'cheap thrills.' To maintain these standards, native groups require a precise amount of time for the preparation of psychedelic concoctions, and the mixture of ingredients must be exact. Even then, there may be an initial period of bodily discomfort, physical pain, or vomiting, followed by encounters with the malevolent entities thought to inhabit these realms.

Paradoxically, psychedelics foster creative behavior among native people by *reinforcing* the cultural myths and traditions. The *ayahuasca*-ingesting Siona shamans of the Amazon do not experience random images; rather, their experience is an ordering of the induced visions into culturally meaningful symbols and experiences. On the other hand, psychedelics often stimulate creativity among specialists in industrialized societies by *deconditioning* them to their cultural traditions; in contrast to

tribal shamans, their images are likely to tap into their personal rather than their social *imaginario*.

Creativity and Reverie

The term 'reverie' is defined in various ways, but it is usually said to be 'dreamlike' in that it is involuntary, fanciful, and imaginal, although it does not occur during nighttime sleep.

Creativity and Hypnagogia and Hypnopompia

Investigators of intuition have reported an association with hypnagogic (from the Greek *Hypnos*, or sleep, and *agogeus*, or leading into) reverie, the thoughts and images occurring during the onset of sleep. There is a similar association between intuition and hypnopompic (from the Greek *Hypnos*, or sleep, and *pompe*, or leading out of) reverie, which occurs as one awakens from sleep. These transitional states, referred to as hypnagogia and hypnopompia, resemble dreams in that both are marked by 'primary process' thinking and contain visual, auditory, and/or kinesthetic imagery. However, material from these twilight states is not typically characterized by narration, as with dreams. Hypnagogic imagery may render more obvious those images involved in scientific creative activity. Indeed, hypnagogic images seem to have been a critical factor in chemist Friedrich August Kekulé's conceptualization of the structural formula of the benzene molecule. Ludwig van Beethoven reported obtaining inspiration for a composition in 1821 while napping in his carriage en route to Vienna. William Blake claimed that images of spiritual beings started coming to him as a child and served as the basis for many of his later drawings. Thomas Edison often stretched out on his workshop couch; during these 'half-waking' episodes, he claimed that he was 'flooded' by creative images. Mary Shelley reported that her classic tale, *Frankenstein*, came to her as a series of hypnagogic images the evening after her group of friends agreed to compete for the best original Gothic horror tale (Shelley won).

Creativity and Daydreaming

Autobiographies and biographies reveal a number of prominent individuals who seemed to utilize various types of daydreaming for creative purposes. Isaac Newton claimed to have solved many vexing problems in physics when his attention was waylaid by private musings. The composer Claude Debussy used to gaze at the river Seine and its playful reflections of the sun to establish an atmosphere for his creativity. The writer Friedrich Schiller kept rotten apples in his desk drawer, claiming the aroma helped evoke creative reverie, while the philosopher John Dewey observed that creative conceptions frequently occur when people "are relaxed to the point of reverie." Jerome Singer and associates found evidence in both children and adults of frequent daydreaming among those whose written or dictated stories were rated by judges as the most original and creative. Singer's team also reported that, during passive, effortless indulgence of a wish in fantasy, eye movements were significantly less frequent than when subjects actively tried to suppress the fantasy or to speed up their thoughts. This essentially passive and uncritical condition is typical of some types of creativity.

Cross-Cultural Comparisons

The way a culture conceptualizes creativity automatically restricts it to some social practices and processes and denies it to others. During the heyday of Maoist thought in China, creativity was a matter of teamwork, and no individual artisan was allowed to sign a painting, claim authorship for an orchestral piece, or register credit for an invention. For spiritual reasons, the composers of Indian ragas did not affix their names to their works, and in the Benin culture, the African deity Olokun is thought to influence artists through dreams and reverie. There are any number of societies in which specialists are encouraged to put aside their rational problem-solving modes of thought in order for divinities to work through them.

Creativity, Meditation, and Hypnosis

There are psychophysiological markers for hypnagogia, hypnopompia, and napping. In the case of meditation, a number of studies have identified markers such as reduced respiration rate and volume of air breathed, reduced oxygen consumption and carbon dioxide elimination, and reduced blood lactate. In these studies, heart rate and the skin's electrical conductance decreased, but the frequency of alpha (and sometimes that of theta) brain waves increased. All of this suggests reduced energy metabolism, autonomic nervous system arousal, cortical energy metabolism, autonomic nervous system arousal, and cortical arousal. Additional research indicated that reduced arousal during meditation is due to its rest and relaxation aspects rather than to the specific meditation practice employed. However, it is probably more accurate to speak of "meditative states of consciousness" than to hypothesize a single "meditative state," because different practices may emphasize rapid breathing and active movement rather than counting breaths, repeating phrases, focusing on a mandala, or witnessing one's thoughts.

Creativity and Hypnosis

The term 'hypnosis' is used to refer to a variety of structured, goal-oriented procedures in which the suggestibility and/or motivation of an individual or a group is enhanced by another person (or persons), or by oneself. These procedures attempt to blur, focus, and/or amplify attention and/or mentation (e.g., imagination and intention), leading to the accomplishment of specified behaviors or experiences that reflect expectations and role enactments on the part of the 'hypnotized' individuals or groups who attend (often with little awareness) not only to their own personal needs but to the interpersonal or situational cues that shape their responses. Other research data emphasize the part that attention plays in hypnosis, enhancing the salience of the suggested task or experience. Both these bodies of hypnosis literature stress the interaction of several variables, suggesting that there are great individual differences in hypnotic responsiveness; some excellent participants are fantasy-prone, others dissociate easily, and still others are highly motivated to be 'hypnotized.' Both hypnotic susceptibility and creativity are fairly stable personality traits, as measured by several standardized tests. The research on

hypnosis and creative phenomena has shown that fantasy and absorptive experiences are concomitants of various changes in consciousness, including those due to hypnosis; they occur spontaneously in the context of a creative act; and they are often experienced by creative subjects who, as a group, seem more adept than their less creative peers at shifting cognitively from a higher to a lower level of psychic functioning – from a more active to a more passive condition. In addition, the ability to tolerate unusual experiences and become absorbed in a variety of experiences correlates highly with hypnotic susceptibility. Time distortion in hypnosis has been used to facilitate the expressive arts and creative writing. Benefits from hypnotically enhanced rehearsals have been reported by actors and performing artists.

Because of the link between hypnosis and creativity, practitioners need to know with what degree of facility a hypnotized subject can produce pseudo-memories. Even the increase in memories later found to be accurate is often accompanied by an increase in memories found to be inaccurate. These pseudo-memories attest to the subjects' creativity, but are often used inappropriately in psychotherapy.

Creativity and Meditation

The term 'meditation' (from the Latin *meditatio*, or thinking over) refers to a variety of practices that are used to self-regulate one's attention. All meditative practices attempt to bring the mediator into the 'here and now,' breaking through habitual patterns of behaving and experiencing. The case for increased creativity during meditation rests on a practice's ability to assist the mediator to break through socially ingrained patterns of perceiving and conceptualizing the world. If the linear, cause-and-effect way of thinking can be transcended, creativity may result. Creativity may be further enhanced by adopting a more circular way of thinking in which the focus is on relationships, possibilities, and recursive patterns rather than on linear causality and single-outcome events.

The research on meditation and creativity has produced mixed results. One group of researchers found no relationship between creativity test scores and experience in meditation. Another group reported significant increases in creativity scoring among practitioners of transcendental meditation (TM) and among Zen meditators. One of the latter studies focused on students of Zen koans, finding that they were able to eliminate prior approaches interfering with problem solving and enhance the unification of contradictory events.

Patricia Carrington has reported several cases of students whose grades have improved, whose emotions have stabilized, and whose artistic productions have flourished following their initiation of a meditation practice. At the same time, in a comparison of a group of teachers of TM with a group of nonmeditators, the former did no better than the latter on most measures, worse on a few measures, and better on one measure – an open-ended task requiring them to make up a story. It seems that meditation may enhance the free flow of associations and open up new ideas for a mediator, but an abundance of meditation (probably the case with the group of teachers) may interfere with a person's logical problem-solving capacity. A meta-analysis of all existing studies of TM and 'self-actualization'

concluded that the magnitude of the effects was not due to expectation, motivation, or relaxation, but to TM practice itself.

Cross-Cultural Comparisons

Eastern and Western meditative practices have a long history; they have been viewed as spiritual exercises – means for attaining the special kind of awareness that can be arrived at in concert with other life practices. In contemporary industrialized societies, however, meditation tends to be oriented toward practical goals, with no ties to a specific belief system. The advantage is that one is free to use meditation outside a spiritual context, combining it with other methods of self-development and health-oriented or psychotherapeutic treatment. The disadvantage is that one may not attain the peace of mind of the unitive ‘bliss’ claimed by members of traditional schools of meditation.

The history of hypnosis is more recent. In the middle of the nineteenth century, James Braid introduced the term ‘neurohypnotism’ or ‘nervous sleep’ (from the Greek *hypnosis*, or sleep). However, it can be claimed that the roots of hypnosis reach back to tribal rites and the practices of shamans. Hypnotic-like procedures were used in the court of the Pharaoh Khufu in 3766 BCE; priests in the healing temples of Asclepius induced their clients into ‘temple sleep,’ and the ancient Druids chanted over their clients until the desired effect was obtained. Herbs were used to enhance verbal suggestion by native shamans in pre-Columbian Central and South America. It is, nonetheless, incorrect to label these procedures ‘hypnosis’ simply because they drew upon similar procedures such as suggestion, repetitive stimuli, and expectations of the client. People, groups, and cultures are ‘creative’ during those periods of time when they exhibit activities that are innovative for that specific group in ways considered valuable by a society. These novel concepts, objects, and behaviors (e.g., a scientific discovery, a mathematical theorem, a philosophical insight, an artistic masterpiece) can be considered creative, although one social group might arrive at a consensus different from that of another group.

Possible Mechanisms

Art involves the controlled structuring of a medium or material to communicate as vividly as possible the artist’s personal vision of experience. If art resonates with a larger public, it has succeeded in filling some gaps in social knowledge or in resolving cultural contradictions. Artists also are attempting to supply missing information or material in a culture’s legacy. The same can be said for creative individuals who work with ideas, institutions, and other people. But none of this labor is done in a vacuum; there are neurophysiological predispositions that interact with social and psychological variables in the development of a product, process, person, or press that is eventually deemed creative.

Neurophysiological Mechanisms

There are several perceptual mechanisms ordinarily driven by sensory input during one’s baseline state of consciousness

that are decoupled, totally or partially, from sensory input during many alterations in consciousness. A total decoupling takes place during dreaming, while partial decouplings take place in hypnagogic or hypnopompic states, daydreaming, meditation, and some drug-induced or hypnosis-induced conditions. Transitions from such states represent a fertile ground for the development of creative ideas, because the perceptual mechanisms automatically linked to organizing the sensory inputs would still occur, occasionally constructing novel and useful images from fragments of internal neural noise and loosely guided consultations with memory. Language allows the abstract images and relationships to be translated into a communicable form. There is a direct relationship between perceptual processes and creative thought. The decoupling of normal sensory input during alternative states of consciousness should be viewed as distinct from restricting sensory input in an individual’s normal waking state in order to prevent interference with controlled manipulation of perceptual codes.

Psychosocial Mechanisms

The forms in which creative experiences are expressed cannot be separated from the person and the culture of which he or she is a part. Cross-cultural research has demonstrated that patterns of expectation within a particular culture have an *a priori* influence on creative experiences.

The effects of psychedelics upon creativity depend on more than their neurophysiological effects, which are produced by an interaction between pharmacological drug factors (type or dose), long-term psychosocial factors (culture, personality, attitudes, knowledge, beliefs, prior experience), immediate psychosocial factors (mood, expectations, group ambience), and situational factors (setting, instructions, implicit and explicit demands). For example, anthropologists who have observed the effects of *ayahuasca* among indigenous people in the Amazon comment that these differ, sometimes strikingly, according to the environmental and ceremonial background against which the drug is taken, the ingredients used in its preparation, the amount of it imbibed, and the expectancies on the part of the intoxicated.

Research Perspectives

The formal study of creativity dates back only to J. P. Guilford’s 1950 presidential address to the American Psychological Association, in which he urged his colleagues to pursue this overlooked area. After the connection between changed states of consciousness and divergent thinking was made, and investigations of the link among drugs, hypnosis, and creativity ensued, studies of additional altered and transitional states followed. Several studies examining the performance of scientists on lateral thinking tests found that highly creative scientists did not use lateral thinking more often than less creative scientists on these tests.

Learning from the past

A seminal research project was undertaken during the 1970s by R. K. Siegel. He conducted a systematic study of visual

images produced by a variety of drugs, focusing on such varied dimensions of these images as color, movement, action, and form. Siegel's subjects were trained to use an image classification system prior to the drug sessions. There were baseline and placebo sessions for comparative purposes. With regard to reported images, the amphetamine (a stimulant) and phenobarbital (a sedative) sessions did not differ from placebo sessions. However, the sessions with mescaline, LSD, psilocybin, and a synthetic compound based on the active ingredients in marijuana produced similar images. In the psychedelic drug sessions, for example, complex images did not appear until well after there was a shift to lattice tunnel forms; memory images emerged in the later stages of the appearance of complex imagery. Noting that hypnagogic and hypnopompic images were accompanied by theta and low-frequency alpha brain waves, other researchers used biofeedback to teach subjects how to enter these states. There was an expected increase in the subjects' awareness of internal imagery and dream recall. What was unexpected was that most of their subjects reported an increase in 'integrative experiences' and 'feelings of well-being.' These positive changes were amenable to intuition, insight, and creativity.

Several questions regarding the research on hypnosis and creativity remain unanswered because of the absence of robust findings due to methodological differences in the studies, the varied hypnotic responsiveness of the subjects, and the fact that creativity has been measured in disparate ways. Even when similar tests are used, they are administered differently, and the tests themselves admittedly assess a single instance or aspect of creativity. It may be that restrictions in awareness increase the priming of associative networks (outside of one's awareness) by reducing cognitive interference. As a result, new associations are made, giving rise to creative insights. Imagination or fantasy provides a continuous backdrop to mentation outside of awareness, and hypnosis may increase its accessibility. Heart rate probably reflects shifts of attention from external to internal events, making it a potentially revealing way to assess the oscillation of attention from an external focus of concern toward the internal events they trigger, a process which is one aspect of creativity. A significant relationship has been reported between heartbeat rate variability and subjects' creativity scores, as more creative persons tended to show higher cardiac variability. The psychophysiological studies of Zen meditators and yogic meditators revealed basic differences: members of the former group demonstrated 'openness' to external stimuli but were not distracted by them, whereas members of the latter group demonstrated 'detachment' from external stimuli. In the light of this diversity, it is important that the type of meditation studied be identified in the assessment of research reports, as well as the length of time the subjects had been meditating. Further, it is common for meditation to blend into sleep during an experiment; hence, the images reported may be the result of hypnagogia and hypnopompia and not meditation itself. The application of chaos theory to the study of creativity has produced several insights, among them a description of how chaotic activity patterns in the brain can reconcile convergent and divergent problem-solving processes, and how 'chaotic attractors' can utilize the brain's neural networks to combine images and thoughts that would escape detection during wakefulness.

Planning for the future

Future research might identify the extent to which individual differences in the recall of content from changes in consciousness might relate to instances of insightful creative thought, as well as to individual differences in attention and perceptual organization. Such data could provide a better grasp of the degree to which information processing in altered or transitional states actually constitutes a major source of creative productivity. Mental constructions occurring during such states can be useful only insofar as they are remembered and can then be evaluated for application and worth. It may be that the degree to which decoupled automatic perceptual processes contribute to creative output has far more to do with facility in higher level cognitive processes such as memory storage, retrieval, search, and comparison than in individual differences in the perceptual organization processes themselves.

One common view of why individuals who manifest some of the streams of schizophrenic-like thought might be viewed as creative is that deficiencies in the normal involuntary perceptual organization processes lead to an increased likelihood of an atypical representation of a perceptual event. In other words, it may be the anomalous organization of sensory input coupled with sufficiently appropriate higher order processes to evaluate the potential value of a mental construction that lead to creative output. However, creativity attributable to looseness in perceptual organization in the presence of stimuli is very different from creativity attributable to perceptual organization processes decoupled from normal sensory inputs. An increased frequency of transitions from transitional states of consciousness, as might be reasonably expected to occur in association with certain psychotic disorders, combined with unimpaired, or even superior, mechanisms of perceptual organization, thus represents a potential alternative route for contributing to creative thought by those individuals who are disposed toward cognitive disorders. Moreover, the relative weakness or looseness in organization processes, and the ability to exploit involuntary organizational processes decoupled from sensory input, may be distinct individual difference variables, both of which might relate to creativity in the general population.

In this regard, what Richards has dubbed 'everyday creativity' is an overlooked phenomenon in a field which all too often emphasizes the exotic, the dramatic, and the spectacular. It is quite likely that creative work draws more upon the ordinary waking state with its intact subsystems of consciousness than upon altered and transitional states. Drugs can be ingested, meditation can be practiced, hypnosis can be utilized, and the contents of reverie can be recorded, but everyday behaviors and experiences can also provide inspiration for what later may become a novel approach to a long-delayed home repair, an improved golf stroke, a new recipe for a family dinner, a breakthrough in a troubled relationship, an ingenious logistical plan to divert restaurant leftovers to homeless people, a challenging educational technology, or any one of many other achievements. The need for creative approaches at all social levels has never been greater; their development and application need to reflect the concepts of 'origin' and 'making,' which so appropriately grounded the Latin word *creare*.

Glossary

Analogical thinking Applying structured knowledge from one domain to help in understanding, explaining phenomena or developing ideas in another domain.

Mapping The process of determining the correspondences between the source and target domains in analogical thinking.

One-to-one correspondence The principle that objects and relations in a given domain are mapped to one and only one corresponding object in the other domain in an analogy.

Parallel connectivity The principle that objects in matching relations also must correspond to one another.

Retrieval The process of bringing known information to mind, specifically the source analog in the case of analogical thinking.

Source The more familiar domain that serves as the base of knowledge to be applied to the less familiar domain in analogical thinking.

Structure-mapping theory The account that states that analogy is characterized by aligning the source and target domains to find their common relational structure.

Systematicity The principle that matching relations that are connected to higher order relations are preferred over those that are more isolated.

Target The less familiar domain about which a reasoner learns more from applying knowledge from a familiar domain.

Introduction

An important cognitive process that underlies creativity in many fields of endeavor is analogical thinking. In an informal sense, analogical thinking can be described as using what you know about one topic to understand another topic, that is, making advances in X by noting that X is in some way like Y. More formally, however, analogy is the application of structured knowledge from one domain, called the source or base domain, to another, called the target domain. Analogy can help in understanding or reasoning about a topic, in generating new products or ideas, in making inferences about what ought to be true about a topic, in communicating ideas, and in persuading others.

The emphasis on structured knowledge in this definition of analogy is important, because it relates to the component processes that make up analogical thought, including retrieval of a source domain, mapping the connections between the source and target domains, evaluating the goodness of a proposed analogy, and projecting inferences from the source to the target. The structure of the source and target domains can be described in terms of objects, simple relations between objects, and higher-order relations or relations between relations. When objects, relations and higher-order relations match across two topics or domains, we have an analogy, and the quality of the analogy is determined by the nature and extent of the match.

Most readers will be familiar with the types of analogical reasoning problems found on various tests of abilities and achievement that take the form of $a:b::c:?$. Problem solvers must determine what item is related to c in the same way that b is related to a. For example, the problem $dog:puppy::cat:?$ would be correctly completed with kitten because kitten bears the same relationship to cat (younger) as puppy does to dog. Note that it is the specific relation that matters, and that there

is a single best answer. Although tabbies might provide a partial match, for example, because dogs and puppies are of the same species and cats and tabbies are of the same species, the link between tabbies and cats does not capture the more specific 'younger than' relation that characterizes dog and puppy. These reasoning problems do possess the essence of finding a common relation across two sets of objects or domains, but analogy and its application to creativity is much richer than these types of $a:b::c:?$ reasoning problems for which there is a single best answer. Most particularly, analogy is useful in solving open-ended problems that do not have single, clear-cut answers and in working with complex domains of knowledge for which the relations of interest may not be as obvious.

Examples of analogy in a wide range of creative endeavors abound, and these examples can serve to illustrate the rich potential of analogy as well as its basic operation. Analogies have been noted to play a prominent role in science, as in the case of Rutherford's use of a solar system as a model for how the hydrogen atom was structured, Darwin's connection between agricultural breeding programs to select for desirable traits in species and the process of natural selection, and Kepler's use of both light and magnetism as sources for reasoning about why planets more distant from the Sun move slower than those closer to the Sun, among others. A classic case in literature is Robbins, Laurents, Bernstein, and Sondheim's adaptation of Shakespeare's *Romeo and Juliet* to the context of a 1950s New York City gang conflict in *West Side Story*. In technology and invention we have Edison's development of an electric light distribution system patterned after the gas distribution system of the day, the Wright brothers' efforts to craft a workable flying machine by analogizing from how a person turns on a bicycle and from thinking of a propeller as a rotating wing, and Georges de Mestral's reliance on the structure of burrs to inspire an idea for a new type of fastener, Velcro. In politics and social influence we have the analogy between Iraq invading Kuwait

in 1990 and Germany overrunning European countries in 1938 and 1939, a connection that may have galvanized US public opinion in favor of military intervention against Iraq. Note that the analogies mentioned in this paragraph vary tremendously in the conceptual distance between the source and target domains, with some being quite distant (e.g., solar system and atom) and others being quite close (e.g., sets of lovers from opposing groups). They also differ in purpose, including explanation, discovery, idea generation, invention, and persuasion. As considered in the section 'Modes of inquiry,' there may also be connections between analogical distance and purpose.

A detailed consideration of some of these real-world instances of the creative use of analogy can help to reveal the key building blocks. In the case of the analogy between the structure of a solar system and the structure of an atom, for example, the solar system is the source domain, about which much was known, and the atom is the target domain, about which chemists of the day were quite uncertain. We can identify matching objects across the domains, such as planets mapped to electrons and the sun mapped to the nucleus. We can also identify matching relations between objects, such as planets orbit the sun mapped to electrons orbit the nucleus. In addition, higher-order causal relations may be involved, such as a causal attractive force that keeps the planets and electrons in orbit. Knowing that gravity is a causal force in a planetary system can reasonably lead to the inference that a comparable causal force is operative at the atomic level, though on a different scale, and the projecting of that inference can thus underlie theoretical development as well as the search for particular types of empirical evidence about atomic structure. Independently of the validity of the mapping, the analogy itself served as an impetus for scientific advances as research progressed on its implications and possible inferences.

Similarly, Juliet and Maria, Romeo and Tony, and Juliet's balcony and Maria's fire escape are among the many matching objects in the deliberate crafting of *West Side Story* as an analogy to *Romeo and Juliet*. Romeo loves Juliet and Tony loves Maria are among the matching relations, as is the connection between the Montagues feuding with the Capulets and the Jets at odds with the Sharks. A higher-order relation is that the dynamic tension created by the conflicting lower-level relations of love and feuding leads to secretive behaviors by the main characters.

The creative power of analogies derives, at least in part, from the fact that good analogies connect the familiar and novel domains at very deep levels, not merely at the surface. Consider the solar system/atom analogy. It means that, just as planets orbit around a more massive central body, the sun, electrons may orbit around a more massive central body, the nucleus. But the nucleus and electrons do not resemble the sun and planets in any superficial way. The nucleus of an atom does not appear yellow to the naked eye like the sun, nor does it have a high surface temperature. The electrons are not as big as planets. What matters is that there are corresponding objects that bear particular corresponding relations to one another. Likewise, New York City of the 1950s did not have to resemble Verona of centuries earlier, and Maria did not have to look or dress like Juliet. What mattered is that two young people were in love, but were also connected to larger groups that were

in conflict with one another. The same type of conflict that drove the story of those star-crossed lovers of Verona drove the story of the more modern lovers.

A Theoretical Model and Set of Processes

As noted earlier, analogical thinking involves set of process, including retrieval, mapping, evaluation and projecting of inferences. In many instances, when people use analogy to create, understand or solve problems in a target domain, they must first retrieve from memory information about a source domain that might be helpful. Thus it is of interest to try to determine what factors determine the likelihood of an analog being retrieved from memory. Having retrieved the source domain, the next step would be to map the corresponding objects and relations in the source and target domains to one another. This is not a trivial problem, because in domains of any degree of complexity there may be many possible mappings between the objects and relations. Consider the attempted persuasive analogy of likening the situation surrounding Iraq's 1990 invasion of Kuwait to events leading up to World War II. The analogical argument in favor of US intervention mapped Iraq to Germany, Saddam Hussein to Hitler, and Kuwait to one or more invaded European countries. The argument was that, rather than pursuing a policy of appeasement as in the initial British response to Germany's invasion of Czechoslovakia, the United States should intervene militarily and stop Iraq before it achieved too much dominance. The object mappings in that case would include Britain of the late 1930s mapped to the United States of the 1990s, since those countries were the ones most dominant in the determination to either appease or intervene; that is, it was the actions of appeasement or intervention by Great Britain that were most relevant in the earlier situation and the potential intervention by the United States that was most relevant in the Gulf War situation. In that case, George Bush, as leader of the United States, would map to either Chamberlain or Churchill as leaders of Great Britain, making for a close relational match. However, the greatest surface-level object similarity would be between the United States of the 1930s and the United States of the 1990s since it is the same country. But that would also mean mapping George Bush as president of the United States, and Franklin Roosevelt as then president of the United States. So, the best relational mapping seems at odds with the best surface level mapping of objects. This conflict between deep and surface similarity can complicate the processing involved in analogical thought.

A particularly influential framework for describing and explaining analogical thought is Dedre Gentner's structure-mapping theory. The core process in that theory is mapping, or matching a familiar source with a less familiar target. The thinker has to find correspondences between the source and target by aligning them and projecting inferences from the source to the target. The alignment process takes into account matches at the level of objects, simple relations and higher-order relations, and ultimately reveals the common relational structure across the source and target.

The alignment process seeks structural consistency, guided by the principles of one-to-one correspondence and parallel connectivity. In one-to-one correspondence, each object or relation in the source domain maps to one and only one object

or relation in the target domain. Consider again the analogy between *Romeo and Juliet* and *West Side Story*. Although the analogy was used by the creators to develop the scenario for *West Side Story*, we can use it here to illustrate the operation of one-to-one correspondence in the comprehension of the analogy and how a viewer might obtain a richer understanding of the stories. Any given character in one of the stories could be put into correspondence with any given character in the other, but in the most sensible interpretation, Romeo maps to Tony and not Bernardo or any of the other male characters. Juliet maps to Maria and not to any of the other female characters. Similarly, using the World War II/Gulf War analogy, a coherent representation, honoring one-to-one correspondence requires George Bush to map to either Churchill or Roosevelt, but not to both at the same time.

In parallel connectivity, the objects involved in relational matches must also match to one another. For example, the relation love each other might map across both stories and the objects participating in that relation, Romeo and Juliet in the one case and Tony and Maria in the other also match. Even though Maria may love her brother or father, neither of them is part of the mapping involved in that particular love each other relation. Likewise, if the United States maps to Britain, Bush should map to Chamberlain or Churchill as part of the leader relation. If the United States maps to itself, Bush should map to Roosevelt as part of that leader relation. According to the structure-mapping theory, people may entertain all possible mappings between objects and relations, but they end up with a single structurally consistent interpretation that honors one-to-one correspondence and parallel connectivity. Interestingly, people asked to think about the World War II/Gulf War connection tend to end up with one of two arrangements. If they match the United States to Britain, they match Bush to Churchill. If they match the United States to itself, they match Bush to Roosevelt.

Having aligned the structures of the source and target, a reasoner can then project inferences from the source to the target. For example, if a reader knows the story of *Romeo and Juliet* well, and knows that the conflict between their love and their families' hatred led them to secretive and risky behavior, and the reader only knows that Tony and Maria are in a corresponding situation, the reader might reasonably project the inference that Tony and Maria will also engage in such actions. Generally, projecting of inferences and generating a preferred interpretation will be influenced by systematicity. That is, in projecting inferences and selecting the mappings to retain, those that are part of bigger causal structures will be preferred over those that are more isolated.

An additional process associated with analogy is analogical abstraction. This involves extracting and storing the abstract structure or schema of what is in common across a source and target or across multiple problems or situations. Consider again the analogy between *Romeo and Juliet* and *West Side Story*. A more abstract way of capturing what the stories have in common is that two individuals love each other but are members of groups that are opposed to one another. This characterization carries none of the specifics of either story, but does represent the conflicting forces that are at work. Such abstractions can be extremely powerful as sources of creative inspiration. A writer might determine for example to set a similarly structured story in the Middle East, in the United States

during the Civil War, in the heat of the Civil Rights movement or any of a huge number of situations in which two individuals might develop a special bond that puts them at risk because of animosities between the groups of which they are a part.

Modes of Inquiry

There are four major modes of inquiry that have been used in coming to understand the nature of analogical thinking. These include case study/anecdotal accounts, laboratory studies, *in vivo* studies, and computational modeling. All of the examples in the introductory section of this article fall into the case study/anecdotal category of investigation. Some are richly detailed, elaborate accounts of specific creative accomplishments, whereas others are shorter reports. Because creative individuals in a number of fields, such as science and invention, leave behind extensive notes regarding their progress on specific problems, it is possible to reconstruct their thought processes, at least to some extent, and draw conclusions about their reliance on a given source domain in understanding or explaining a target domain. Such approaches carry with them a level of uncertainty, in part because the individual's account is retrospective, possibly written well after the major creative accomplishment, raising the possibility that the memory of what actually occurred is inaccurate. In addition, even with contemporaneous notes, creative individuals may not always have a clear sense of all the factors that influenced their thinking. Nevertheless, case studies and anecdotes provide one window into the richness that characterizes analogical thought, particularly in high level, real-world types of creative activities.

In contrast, in laboratory studies, participants (often college students enrolled in psychology classes) are presented with relatively simple, highly constrained problems to solve. Experimenters obtain a variety of measures designed to give insight into the thought processes at work. The participants are not generally experts in any particular domain, such as science or technology, and the problems are typically less complex and open-ended than those faced by experts in those domains. The problems are generally ones that can be solved in the timeframe of a single experimental session, perhaps an hour or so. Because the tasks and situations are somewhat artificial it is possible to question their ecological validity, but what laboratory studies lack in realism is made up for by the precision and certainty with which conclusions can be drawn. Experimenters typically manipulate one or a small set of variables across the situation, and by keeping all other factors constant are able to attribute findings just to those variables.

The laboratory approach can be illustrated with one of the most well known set of experiments on analogical thought, conducted by Mary Gick and Keith Holyoak. In their studies, participants were asked to solve simple problems, such as the tumor problem. The gist of that problem is that a patient has a cancerous tumor that can be destroyed if enough radiation can be brought to bear on it, but a directed dose of radiation sufficient to destroy the tumor would also destroy healthy tissue on its way to the tumor. One possible solution, deemed the correct one, is that multiple, lower intensity sources of radiation can be directed at the tumor from different directions, all converging on the tumor as a focal point, thereby bringing enough

radiation to destroy the tumor but not harming healthy tissue along any of the separate paths. Note that this problem has a single best answer, which experimenters use in determining whether or not people correctly solve the problem.

Participants are unlikely to solve the problem spontaneously, but are more likely to do so if they first solve a problem with an analogous structure. In that related problem, a general has enough troops to overtake a fortress but the troops cannot all reach the fortress along a single path. When participants see the solution of sending smaller numbers of troops along multiple paths, all converging on the fortress, they are more likely to solve the tumor problem by analogy to the general problem. Interestingly, even so, only about 30% solve the tumor problem, unless they are explicitly told to think back to the prior problem. In other words, they have a potential source analog in memory, but do not often spontaneously retrieve it to apply to the new situation. So, the results highlight the importance of distinguishing between, long term memory storage of source analogs, retrieval of those analogs, and mapping of information from the analogs to a new situation.

Other laboratory research on analogy is typically designed to examine separate processes and the factors that influence them, or to test the competing assumptions of theoretical models of analogical thought. This includes research on the factors that determine the likelihood of retrieving particular source analogs, the evaluation of the strength or goodness of the analogy, and the projection of inferences from the source to the target domain. Some of this work reveals the intertwined importance of the distinction between the surface similarity of objects across domains and the deeper structural similarity of shared relations, and the distinction between retrieval and evaluation processes. People seem more likely to bring to mind potential source analogs that are similar in superficial ways to a target probe item, but they evaluate the match as better and the inferential value as greater when there is a similar higher-order causal structure to the target as opposed to superficial similarity. A vitally important implication is that the ideas that come to mind most readily as possible source analogs to help with a current problem are not necessarily the best ones for helping to make progress on the problem.

In vivo studies are designed to have the ecological validity associated with high-level, real-world creative activities in combination with the more direct observation that is characteristic of laboratory studies. The studies generally involve detailed observations of the activities of groups of experts working together on complex creative tasks in domains such as science and technology. A classic example is Kevin Dunbar's observations of molecular biology lab meetings as the groups went about their ordinary research business. The groups were clearly working on real-world creative tasks of great complexity, but by videotaping multiple lab meetings over an extended period of time, carefully coding the tapes for instances of analogical reasoning and other thought processes, and relating those observations to discoveries made, it is possible to develop a more certain picture of thought than would be available just from the scientists retrospective accounts.

Observations of these lab groups lead to important distinctions between near and distant analogies and between different purposes in using analogies. Distant analogies that recruit ideas from source domains that are conceptually very different

from the target (e.g., as in the case of the solar system/atom analogy) are quite rare in the day to day activities of working lab groups. Instead, near analogies, that recruit knowledge from domains that are conceptually very close (e.g., using knowledge about one virus to understand or generate hypotheses about another virus) are the more common mode of thought. Furthermore, the distant analogies that are used seem not to be used in making discoveries, developing an understanding of something, or generating new hypotheses. Instead they serve a more communicative goal of explaining something. If these findings turn out to be general ones that hold true across many areas of science, they would raise questions about how much previous anecdotal accounts of distant analogies really support their causal role in discovery. Perhaps, for example, Rutherford's use of the solar system was a communication device to explain an idea, not the source by which he came upon the idea. More generally, comparing anecdotal accounts to the findings of *in vivo* approaches shows that advances in understanding creative activities are more likely to come from using evidence from multiple methods than from the application of one type of method to the exclusion of others.

Research using the *in vivo* approach can also help to reveal differences between different types of creative endeavors. Observations of design engineers who had the task of developing completely new features for the product that was being designed have shown that they use distant analogies as commonly as near analogies. In addition, although engineers, like biologists, use distant analogies to explain things, they also use them for problem solving, a function much more linked to the creative process itself and not just an after the fact account of the process. Thus, the use of the *in vivo* method has helped to draw attention to the idea that the use of various processes and their value in those endeavors depends on the type of creative task involved.

In the computational modeling approach to understanding analogy, theorists attempt to simulate the findings of laboratory studies on analogical thinking using computer models built around particular assumptions. The advantage of this approach is that it requires modelers to be very specific about the processes and constraints they believe to be relevant. Without that specificity, writing the code to execute the steps would not be possible.

Two major classes of computer models are symbolic and connectionist approaches. The best known symbolic model is the Structure Mapping Engine (SME) that implements assumptions of Structure-mapping Theory. SME uses a predicate calculus and represents knowledge in the form of objects (role fillers, such as Bush, Churchill, Romeo, Tony, and so on), attributes (properties of individual role fillers), first-order relations (predicates with two role fillers, such as president-of (Bush, US), and higher-order relations (predicates that have at least one first-order relation as a role filler). In mapping across the source and target, SME proceeds in stages from local-to-global. In the first stage, all identical predicates and their role fillers are matched, which may result in multiple matches for a given element (e.g., Churchill from the source could match Bush or Hussein from the target because they are all role fillers of the predicate leader). In the second stage, kernels are formed from consistent matches (e.g., the match of Churchill and Bush is consistent with a match between the

Great Britain and the United States, since they are leaders of those respective countries, and those matches would become part of the same kernel). In the third stage, kernels are merged to form the largest structures that are structurally consistent and preserve one-to-one correspondence. Structures that include correspondences involving higher-order relations are preferred over those that do not. The model captures the notion, alluded to earlier, of a preference for higher-order relations in evaluating matches and projecting inferences.

A model of analogy that is inspired by connectionist approaches to cognition is ACME (Analogical Mapping by Constraint Satisfaction), which seeks to implement the assumptions of multiconstraint theory. Like SME, it does use symbolic representations of the source and target analogs, but unlike SME that focuses primarily on structural constraints as noted above, ACME considers interacting constraints of similarity, structure, and purpose in determining the best mapping between the source and the target. Similarity refers to the semantic relations between predicates or objects. For example invade (as in the case of Iraq invading Kuwait) is clearly more similar to occupy (as in the case of Germany occupying Austria) than to leader-of (as in the case of Churchill as leader of Great Britain), thus favoring a match between the former over the latter. The predicates need not be identical to be matched, rather matching is based on the degree of similarity, represented by a numeric code. Likewise, a relationship to the goals of the thinker can be represented numerically, thereby capturing purpose as a constraint on which mappings will be favored. Using excitatory and inhibitory links to represent constraints, and parallel constraint satisfaction to simultaneously or interactively satisfy the three types of constraints, the model seeks the optimal mapping between the source and target domains. ACME has successfully simulated a wide variety of human experimental findings, including the types of connections human research participants see in analogy problems.

Application

Analogy has been a key ingredient in proposals for improving creative functioning, though what counts as analogical thinking in such proposals may be less formal than is true for scientific approaches to the study of analogy. Most widely noted of the applied approaches is the advocacy for the use of different types of analogy as part of synectics, developed by William Gordon. Rather than a single form of analogy, synectics argues for different forms that might meet different purposes or goals. Direct analogy is perhaps closest to the nature of analogy as described earlier in this article. In direct analogy, the thinker applies knowledge, facts or other ingredients from some other source. That source can be ideas borrowed from nature. By considering how living things solve related problems, one might adapt that approach to one's current problem situation. De Mestral's realization that formed the basis for Velcro can certainly be described as a direct analogy. By observing that burrs attach to clothing and can be detached and reattached repeatedly because of a structure comprised of a large number of tiny hooks, he was able to

conceive of a durable, easy to use fastener as an alternative to zippers or buttons. The hooks and eyes as objects, and the relation of hook into, make this an analogy.

In personal analogy, the thinker identifies with the problem or at least a component of the problem, putting himself or herself into the problem, role-playing some part. For instance, in considering the operation of some mechanical invention, the thinker might imagine being one of the parts of the device, and moving the way the part does. In symbolic analogy, there is also identification but with phrases, images, and objects. In fantasy analogy, real world constraints are released and the thinker can consider how the situation would be if what is now impossible were to be possible.

It is clear that analogical thinking has brought about important creative advances in many domains, and thus it is certainly appropriate to suggest that people can behave more creatively if they adopt analogy as a technique. However, there are some important caveats. The first is that it is not always clear how one can retrieve from memory the correct analogy that will be most helpful. It is easy to see the role of a particular analogy in retrospect. For example, the possible match between the structure of a solar system and the structure of an atom is quite clear once the connection has been pointed out and described. But how did the analogy come about to begin with, and how was the source retrieved, as opposed to any of a wide variety of source domains that might have been retrieved that would have been less helpful. In a related way, what makes a good analogy may not necessarily be the same as what makes a source domain likely to be retrieved for consideration. In addition, as noted above it is not always clear that analogies play a causal role in discoveries. Perhaps the solar system was only invoked as an explanatory device to convey the basic idea to others, rather than the source of inspiration for what the structure of the atom must be like to begin with.

A second caveat is that, because they are structured sets of relations, there is a potential that interfering ideas can be brought along with useful ones in an analogy. One example can be seen in Edison's application of the structure of the gas distribution system of his day to the problem of electric distribution for powering his light bulb. Without a system of bringing electricity into homes, most people would not have much use for a light bulb. The analogy was complete and structured, including a central source, conduits for distributing the electricity, and devices to make it accessible in the home. Just as in gas distribution there would need to be some device for measuring usage at each residence, which led to even more invention to meet that need. However, the fact that the gas mains were underground led Edison to the idea of having electrical cables underground, a much more complicated and costly venture than having them above ground. Thus, the notion of structural consistency in the mapping between domains that makes analogies compelling can be the very factor that leads to the inclusion of attributes from the source that are problematic in the target domain.

A final caveat is that analogies are starting points, not end points or magical solutions to problems. Having determined to create a musical by analogy to *Romeo and Juliet* was just the first step in the creative labor that went into the final product of *West Side Story*. Characters needed to be generated

and fleshed out, scenes constructed, songs written, choreography laid out and so on. To take a different example from invention, de Mestral got the idea for Velcro by direct analogy from the structure of burrs, but it took him several years of effort to bring the invention to fruition. This is not to say that analogy is not helpful. It most certainly is. The point is simply to put its role in the creative process into perspective.

Glossary

Bauhaus ('House of building' in German) Name of an avant garde design, crafts and fine arts school, founded in Germany in 1919 by Walter Gropius. Until its closure in 1933 the school operated in Weimar, then Dessau, and finally in Berlin, and had a profound impact on modern architecture, design and art.

Beaux arts Short for Ecole Supérieure des Beaux-Arts ('Higher school of fine arts' in French). The school was founded in Paris in 1648 and became independent in 1863. Beaux Arts schools were established throughout France, the rest of Europe, and later also America. They keyed on classical arts – Greek and Roman architecture, and studying and imitating the Great Masters and the classical orders.

Computer aided design/computer aided architectural design (CAD/CAAD) Computational tools that support designing with various kinds of software.

Deconstructivist architecture A movement within postmodern architecture as of the late 1980s. It is characterized by fragmentation, manipulation of a structure's surface or skin, nonrectilinear shapes that serve to distort and dislocate some of the elements of architecture, such as structure and envelope. The theoretical underpinnings of deconstructivism were largely influenced by the philosophy of Jacques Derrida.

Performatism A contemporary interpretation of performance in architecture, embedded in digital design,

which aims to incorporate functionalist and image-based approaches to form making and conception.

Postmodern architecture A movement and style within the postmodern culture that flourished in the 1970s and 1980s. It came into being largely in reaction against the starkness and uncompromising modernism of the International Style. Postmodern architecture is characterized by the combination of modern forms and materials with a highly conscious use of motifs and conventions from earlier periods including decoration, which was not accepted by the Modern Movement.

Self-unself-conscious design Terms coined by Christopher Alexander. A self-conscious process occurs in a culture undergoing rapid changes that bring about random designed forms because designers are unable to respond to change systematically. Unself-conscious design occurs in a stable culture where occasional and slow changes cause only minor adjustments to robust, failsafe designed forms.

Starchitect A star architect, who produces exclusive, so called 'signature buildings.'

Vkhutemas (Acronym for 'Higher Art and Technical Studios' in Russian) Name of an avant garde art and technical school founded in 1920 in Moscow. It was dissolved in 1930 but was nonetheless responsible for one of the great revolutions in the history of art (constructivism).

Introduction

The history of designing buildings goes back several millennia. It is reasonable to assume that for a long time huts, and later buildings, mostly of modest size, were made to respond to basic needs of shelter. However, social life, which had taken place primarily in the open, eventually also required accommodation in buildings as well. The first known building of a monumental size that is believed to have been the brainchild of an appointed architect is the Pyramid of Djoser in Egypt, designed by Imhotep between 2630 and 2611 BC. Until the modern era, the history of architecture is told through mostly large-scale buildings with symbolic significance erected to house religious, government, cultural, and social functions. The rulers who commissioned them also had palaces designed and built for themselves, to serve as status symbols as much as living quarters. In modern times other building types emerged that acquired architectural prestige (diverse additional cultural centers, commercial edifices, transportation hubs, educational institutions, and more). Residential buildings, other than houses for the very rich, were not considered worthy of architectural attention until rather late in the modern era.

Outstanding buildings do not spring into being by chance, as arbitrary triumphs of creative architects. Exceptional buildings embody ideas that had ripened within a culture or micro-culture and were translated into built form; in return, exceptional works of architecture often extend such ideas and promote further development of architectural theory. Thus the history of architecture is largely a history of ideas; both general ones, which define historic styles, and individual ones that are responsible for outstanding buildings.

The two major aspects that guide the design of any building are function and form. Every building must serve the purpose for which it is being built, and it must have a physical form, which impacts upon both its users and those who perceive it from the outside as part of the environment. The evaluation of form and function is well aligned with the two most prominent measures of creativity: originality and practicality. In the behavioral sciences creativity is often measured as the sum of originality (novelty) and practicality (usefulness) of the outcome of a design undertaking. Although design of any kind is considered to be a creative activity, there are of course designs which are more creative than others, and it is these that are most interesting for this article. The article will touch upon ideas in architecture, and will stress the form-function issue.

It ends with a section on architectural education which is greatly concerned with questions relating to ideas, form, function, and creativity.

Leading Ideas: Self-Conscious Architectural Design

In 'Notes on the synthesis of form' Christopher Alexander, a leading design theorist in the 1960s and throughout the 1980s, distinguishes between 'self-conscious design' (Alexander's original term), as practiced in the modern era by professional designers, and 'unself-conscious design,' which was practiced by people who conceived buildings and other needed structures mainly before design became a formal professional activity in its own right. Unself-conscious design is responsible, well into the modern era, for what is referred to as traditional, vernacular or indigenous architecture, and is highly localized. In 'The appearance of the form' John Habraken recounts how, in the twentieth century, a house was built for a priest in a small Dutch village. The carpenter who was charged with constructing it received the following instruction: "... the priest needed, unlike other folk, a room to study and receive visitors." This was all the information he needed; as for the rest, the carpenter had a very precise mental model of a house in that community, to which he merely had to add the extra room. The mental model addresses the 'style' of the building as well as all other design issues: the size, the room layout, building materials, and so on. In vernacular architecture buildings of the same type resemble each other; examples of the past are followed, and there is no drive to change anything unless it is absolutely necessary. The beauty of such architecture comes from its perfect adaptation to its surroundings and its function, as was cogently shown by Bernard Rudofsky in the MOMA exhibition and catalogue 'Architecture without architects.'

In addition to the general cultural context in which it is embedded, more recent self-conscious design must also be understood in light of a narrower micro-culture to which a designer subscribes. Tradition is no longer enough of a moderating factor, and several approaches or design styles may be concurrently acceptable. Designers seek to belong to professional communities and to that end they subscribe to a micro-culture that best accommodates their values, beliefs and taste. This is a dynamic state, of course: cultures and micro-cultures do not stand still, nor necessarily do one's affiliations. Both traditional cultures and contemporary micro-cultures constrain design in terms of shapes, forms, patterns, and their combinations. There are explicit and implicit rules that designers are expected to follow regarding the spatial world within which they play out their designs. 'Playing by the rules' is in fact one's ticket to membership in a particular micro-culture, or design style. However, the most creative architects are known for their breakthroughs in which the rules are, at least, extended.

Striving for Novelty and Leading Ideas

Contemporary design is highly self-conscious. Architects strive to innovate within the culture or micro-culture to which they subscribe. To be considered creative, architects have to try to

push the boundaries of what is acceptable. In other words, they try to distance themselves from the typical in favor of a new and surprising design solution. More often than not, novelty rests on a 'leading idea' which drives the design. A leading idea in architectural design may be related to any one of different aspects of a building: spatial organization, building performance, the forms used to enclose spaces, façade composition, building materials, structural system, and so on.

Self-consciousness in design and the leading ideas that epitomize it are not restricted to contemporary times, of course. The Italian Renaissance architect Filippo Brunelleschi earned his fame mostly by devising a way to build the largest dome of his time, that of the Duomo of Florence, Santa Maria del Fiore. His creative contribution was the structural system of the building. The contemporary architect Santiago Calatrava also built his reputation on the ingenuity of his structures, many of them bridges. In both cases the structural solutions are responsible for the striking architectural quality of the ensuing buildings. In contrast the Swiss architect Le Corbusier, considered one of the greatest architects of the twentieth century, designed the residential building Unité d'Habitation in Marseille, France (1955), where the innovative feature was the spatial organization of the building. In this 12-storey building, which includes commercial and community facilities along an inner 'street' at mid-height, corridors run every third floor, leading to two-level apartments that span, on one of the levels, the entire width of the building. A very well known example of creative architecture due to novel building forms is the Guggenheim Museum in Bilbao, Spain, by Frank Gehry, completed in 1997, which, like other Gehry buildings, is composed of bold large curvilinear forms. Somewhat less known is the fact that the building also boasts an unusual application of a cladding material – sheets of titanium. A building that owes its fame entirely to the novel building material chosen for its enclosure is the Beinecke Rare Book Library at Yale University, designed in 1963 by Gordon Bunshaft of the firm of Skidmore, Owings, and Merrill. All exterior walls of the building are made of translucent marble, which transmits subdued lighting and provides much needed protection from direct light which would have harmed the rare manuscripts the building houses.

What the above examples have in common is the fact that all of them offered entirely new solutions to at least one major architectural aspect. These architects did not follow precedents and succeeded in making a significant breakthrough by offering an entirely new way of treating that particular aspect. In terms of problem solving, it may be claimed that the novelty of the architectural solutions in these cases stemmed from a conscious breach of the habitual problem space (design space, in this case) in which the architects searched for a solution. Despite their novelty, however, even exceptional works of architecture continue to be embedded in their cultural circumstances, and are identified by a style or movement they belong to (which, in extreme cases, they help create).

Styles and Paradigmatic Shifts

Styles and micro-cultures are based on overarching ideas over which there is a consensus within the relevant communities at a given period. Such ideas are encompassed in theories,

expressed in writing, often in the form of treatises. The earliest treatise still referred to today is by Vitruvius, a Roman architect and theorist who lived in the first century BC. His writings were rediscovered in the Renaissance and have had a lasting impact on architectural thinking and practice. Fil Hearn compiled the most important treatises throughout history and demonstrated the key role they played in shaping important works of architecture. Architectural styles are rooted in shared formal theories and the appearance of each style is accompanied by corresponding treatises.

The twentieth century saw the rise of three major styles: modernism, postmodernism, and deconstructivism. The modern movement was born at the turn of the nineteenth century. It strove to free buildings from formal historic compositional principles and excessive decoration, and to make them more suitable to the new lifestyles of a more egalitarian society that recognized everyone's right to live and work in improved built environments. With the social motivation, formal design principles were also widely accepted, including regularity rather than axial symmetry as an organizing principle, the breaking of large masses into smaller volumes that form three-dimensional compositions, and the removal of decoration in favor of surface composition of facades as the main aesthetic appeal of a building. In the 1920s two new design education programs were launched, at the Bauhaus in Germany and the Vkhutemas in Moscow. In both schools the new ideas of modern architecture underpinned the curriculum, in contrast with the prevailing neo-classical approach that was the rule in Beaux Arts schools throughout Europe and North America (for further discussion on this topic please see 'Architectural Education' below).

Following an exhibition at the MOMA in New York in 1932 the ensuing style was dubbed 'International Style,' a term advanced by Henry-Russell Hitchcock and Philip Johnson, who were the exhibition curators. Although the style was born in Europe and crossed the ocean to North America, today one of the largest concentrations of International Style buildings (some 4000) is to be found in Tel Aviv, Israel; the area in which they are concentrated is called White City as these buildings are predominantly white. The style was brought there by the many immigrants from Europe who arrived in Palestine in the 1930s and 1940s. In 2003 UNESCO proclaimed The White City of Tel Aviv a World Cultural Heritage site.

Postmodern architecture emerged as part of a wider cultural shift. It was mainly a stylistic tour de force, which rejected the austerity of modernism and embraced, once again, historicist and decorative connotations. Postmodernism was permissive rather than purist. For the first time the envelope of a building no longer had to express the volumes and spaces it enclosed and acquired an independent status of its own. Therefore, the modernist slogan 'form follows function' lost its currency during the postmodern era.

In the late 1980s a further stylistic development within the postmodern culture brought about deconstructive architecture, which was heavily influenced by the writings of the French philosopher Jacques Derrida who coined the term 'deconstruction.' The term refers to the close analysis and breaking up of texts into fragments that are not necessarily seen as coexisting harmoniously. In architecture, deconstructive work is characterized by

fragmentation of building volumes to the point of tension among them, non-rectilinear shapes, often with sharp angles, and a dismissal of any formal commitment to building typology, which was important to modernist architects. In architecture deconstructivism (also known as deconstruction) is also akin to constructivism, a movement in art and architecture in Russia that was active from 1919 until 1934. The constructivists were part of the modern movement, but had a more radical and innovative approach to the treatment of shape and form.

Architects who pioneered these styles forged and developed the ideas that defined the styles, along with theorists and historians whose writings helped lay the foundation for the movements' theoretical underpinnings. Needless to say, there have always been voices that proclaimed other ideas, away from the mainstream. When postmodernism reigned, a smaller movement called regionalism advanced different ideas: in opposition to the universalism of postmodernism they preached localism: respect for local culture, building traditions, and so on. The deconstructionist era also saw, in parallel, a growing concern for the environment which was finally embodied in a movement for sustainable architecture, now also referred to as 'green architecture,' which emphasizes the measurable performance of buildings (but not in opposition to spatial excellence). At present no major style reigns in architecture (unless digital design is treated as a style; see 'The Digital Shift' below). This does not preclude new theories from influencing both practice and discourse about architecture. An example is the books by the architect Rem Koolhaas that have had more impact than the buildings he designed.

The Form-Function Dichotomy

The dictum 'form follows function' is attributed to Louis Sullivan, a prominent American architect who was active when steel first became a primary building material late in the nineteenth century, used for the construction of building frames. Steel frames, along with the introduction of the elevator, made it possible to build taller buildings and Sullivan is known as a pioneer of skyscraper design. This building type, completely new at the time, with the new design issues it brought with it, emphasized a renewed interest in functional aspects of architectural design. The turn of the century was a time in which many social and technological changes took place that encouraged a willingness to break away from conventions that had dominated in architectural design until that time. The new attitude was the background to the growth of the modern movement which, not surprisingly, endorsed 'form follows function' to the point of turning it into a slogan. Form and function were always conceived as two complementary but dichotomous parameters that define architecture. This is not to say that form or function are, or can be, mutually exclusive: both are musts in architecture. The relative weight attached to one or the other places a work of architecture within a defined category from an historic perspective and, within a given cultural context, it helps classify works of architecture as well as architects. Form and function also represent the two facets of creativity: originality and practicality. With few exceptions, originality is expressed mainly in the treatment of form, whereas the way a building functions is obviously chiefly related to practicality.

Modern architecture was heavily committed to thorough functional analyses and incorporation of ensuing requirements in any design program. Building types were defined and investigated, and a rich technical literature was developed to guide architects in providing appropriate responses to predefined programmatic needs. Form was expected to follow closely the allocation of space that resulted from a functional analysis. Consequently, the building form was expected to express its function and its typological affinity; that is, a school had to look like a school, and a city hall like a city hall.

During the 1960s a concentrated effort was made to introduce systematic, scientifically-based design methods into architecture. A number of international conferences related to methods were held, most of them in the United Kingdom, as part of what came to be known as the 'design methods movement.' Many of the methods in question were adapted from engineering and management, and their goal was to optimize design outcomes by ensuring that all relevant issues would be addressed properly. The methods that were developed were prescriptive in nature, specifying design steps and their sequence. Two decades later it became clear that despite the efforts invested in design methods, they had failed to have an impact on either practice or education. There was more than one reason for this failure. First, the methods were very laborious and technical, and architects felt that they crippled their creative initiatives. Second, high hopes for automated processes in which computers would play a decisive role had left designers disappointed: computational technologies were far from capable of delivering the desired results. Third, and possibly the most important reason for the failure of 'methods' was the fact that with the advent of postmodernism, satisfying functional design requirements had lost its priority in favor of articulating form, or more specifically, the independent design of a building's envelope, into which spaces were fitted that accommodated the building's program. Exciting façades became so important that Robert Venturi and Denise Scott Brown, prominent architects and contributors to post-modern architectural discourse, wrote 'Learning from Las Vegas,' in which they talked about the acceptability of even the most simplistic box-like buildings, provided a well-designed façade was attached to them like a billboard or very large advertisement. The consequences of this theory are discernible today in places like Times Square in Manhattan.

Today the approach to function and form is more balanced. However, the term 'performance' has replaced function in discourse. The change of term signifies commitment to a higher-level scrutiny of building requirements, which is made possible with state of the art computational tools.

The Digital Shift

Computers have permeated design as they have pervaded almost every other area of life. The use of computers in design goes back to the 1960s, notably with the landmark system Sketchpad developed by Ivan Sutherland at MIT. By the 1980s CAD (computer aided design) and CAAD (computer aided architectural design) became established research fields, taught in schools of architecture, and making their way into practice. Early computational tools were seen as supporting

design in several ways, from drafting and the creation of fast and lively renderings, to flexible instantiations of designed objects through parametric control over design constraints. Specific programs were written for various building performance aspects, for example, the determination of window sizes and shading requirements for best climatic performance.

Digital design technologies have made enormous progress since then, and many will agree with Branko Kolarevic who wrote in 2003 that "Digital technologies are changing architectural practices in ways that few were able to anticipate just a decade ago." Today's advanced digital design systems have generative capabilities and they are able to create and transform non-Euclidean geometric spaces and transform them in the blink of an eye. Frei Otto designed the roof of the Olympic stadium built for the Munich games in 1972. The structure, considered very innovative for its time, consisted of large sweeping curvilinear canopies. During the design process Otto had to model the forms he was designing manually with elastic fabrics (allegedly he used ladies' stockings), as there was no way to represent their geometry accurately otherwise. Today structures like this are easy to model digitally. Moreover, up to a certain size complex forms can be manufactured with no need for any intermediary representation other than the digital model, which is fed into a CAM (computer aided manufacturing) system. CAD-CAM systems are already ubiquitous at high-end industries such as airplane and car production plants.

One of the immediate impacts that these new capabilities are having on architecture is the ability to break away from the straight line in favor of an 'emancipated' world of rounded and curvilinear forms. This includes many varieties of spatial expression, some of which are sometimes referred to as 'biomorphic.' The term suggests a trend to emulate natural forms that, at different scales, are by and large composed of non-Euclidian, curvilinear shapes and forms. This world of forms had been lost to architecture until now because it was not possible to represent and specify them properly, as in the case of the Munich Stadium. Now that this has become possible, architects are at liberty to explore a whole new array of spatial forms, and some of them, especially young architects and students of architecture, are happy to immerse themselves in this new and challenging universe.

Since buildings are usually large and to date must be constructed, or at least assembled in situ and not manufactured like cars or other artifacts, it is still very difficult and expensive to build structures which are neither regular nor modular, and may not include any repetitive elements. The building industry thus faces a serious challenge that will determine the pace at which biomorphic structures will turn from exciting digital projects into buildings in the real world.

Digital design is largely preoccupied with form, but it also advances the designer's ability to model and therefore predict and control the building's performance. Alternative values and tradeoffs can be tried out quickly and inexpensively in order to arrive at an optimal or balanced performance. The centrality of the issue of performance has led to a branch of digital design known as 'performalism.' Performalists stress the need to advance digital design not only in terms of forms and their production, but also in terms of the way they respond to needs, both needs of their own technical systems ('clever buildings') and the needs of the people who inhabit and use them.

The options that digital design opens up are vast and potentially revolutionary, and at present it is impossible to anticipate where they will lead. How will people relate to complex forms of such different geometries? How will structures relate to one another? Today they are treated rather as discrete objects, whereas there is generally a preference for thinking of buildings within contexts, primarily urban contexts, where continuity and coherence of a broader urban fabric are sought and open urban space is planned to complement buildings with equal heed and prudence. What would such an open space be like if the buildings that abut it were all composed of forms that were convex and curved onto themselves and usually turned a concave and possibly alienating face to what surrounds them? How will people inhabit and furnish curvilinear spaces should they be severely constrained in size, in contrast to vast spaces in the mostly virtual designs that can be experienced today? Will new building materials make it possible to manufacture structures and maybe allow them to be transformed routinely throughout the life-cycle of the building? What will such a cycle be? And how would regulatory forces adapt themselves to the new realities?

But most importantly, the new technologies pose questions regarding the very act of design, and the role of the architect. The new systems are imbued with intelligence that allows them to generate form, transform and evaluate it, often surprising the designer who, having provided a certain information set, may receive unexpected outcomes. The architect will most probably continue to make the decisions, but what decisions? Is he or she to choose from among proposals obtained digitally, adjusting the input more or less randomly so as to come closer to satisfying constraints or requirements? Who will determine the constraints and requirements, or the goals? In other words, conventional artificial intelligence as it is known today will no longer suffice; it may become necessary to talk about a higher digital intelligence, and digital creativity, at least as far as design is concerned. Such intelligence and creativity will have to be pitted against the architect's creativity and intelligence. The old question regarding the nature of the partnership between the designer and the computer in the design process has never been as acute as it is today. It is hard to predict what architecture and architectural practice will be like a decade or two from now, but it is certain that the digital shift which is occurring as these lines are written will have a profound and irreversible impact on built form and its production as they have been known and practiced until the present.

Starchitects and Other Practitioners

Although architectural design, and design in general, are creative activities by definition, not all works of architecture are equally creative, nor are all architects uniform in their creativity. In a paper published in 1962 Donald MacKinnon presented a study of personality correlates of American architects, in which he found that there were significant personality differences between more and less creative architects (creativity correlated positively with for instance higher levels of affective intelligence, openness to experience, freedom from petty restraints and impoverishing inhibitions, aesthetic sensitivity, cognitive flexibility, independence in thought and action,

high level of energy, unquestioning commitment to creative endeavor, and unceasing striving for creative solutions to ever more difficult architectural problems).

In a book published in 1998, the sociologist Garry Stevens looked at architectural practice and found it necessary to distinguish between architecture as a field and architecture as a profession. The profession is the more mundane of the two; it represents the business of designing buildings for clients to fulfill defined purposes. In their capacity of architects working in the profession, architects provide design services to clients, be they owners, users, or representatives of public or private organizations. It is a business-oriented activity in which architects try of course to excel, while being highly client-minded and constrained by the client's directives. Expertise is much valued in the architectural profession, and there are firms that develop special expertise in a particular building type, for example, hospitals.

The architectural field transcends ordinary practice. It is more concerned with innovation and with a cultural discourse through writings and built form. Architects who operate in the field of architecture are privileged; they see themselves, and others regard them, as practicing at a higher level than other professional architects. They are status oriented and instead of being client-minded they are eminence-minded. They hope to produce landmarks, rather than buildings that 'just' serve their users well. Clients turn to architects of this kind when they are interested in a product that would serve as a status symbol, and are willing to compromise some of their control over the building program and design decisions. They are also willing to pay higher fees, in addition to higher construction costs.

Stevens calls the architects in this group 'the favored circle.' Those at the top of the list are known to us as 'starchitects': they become cultural heroes, even celebrities, and their iconic buildings – 'signature architecture' – are included in lists of attractions to be visited by tourists. A well known case in point is the Guggenheim Museum in Bilbao, Spain, completed in 1997, by Frank Gehry. The building is said to have done wonders for Bilbao, then an industrial city with a decaying economy, by bringing in an average of close to one million tourists each year (about eight times the number before the building was built). The project costs were overwhelming (over 200 million dollars), but the city gained hundreds of new jobs, hundreds of thousands of overnight-stays annually, along with other business that tourism generates.

Starchitects are definitely among the most creative of architects. Their creativity rests primarily on exceptional originality, whereas in terms of practicality they do not necessarily achieve better results than other good architects. In fact, sometimes there are serious functional flaws in their buildings (the Sydney Opera House by Jorn Utzon, completed in 1973, is an example). But striking, original forms are received with so much admiration by the public at large that functional flaws are often met with forgiveness. In this respect, architecture occupies possibly a unique position as far as the balance of novelty and effectiveness in creativity is concerned, and in that it is closer to the visual arts. The Sydney Opera House cannot carry out the function that those who commissioned and paid for it envisaged (the staging of large-scale opera productions). However, because it looks beautiful this flaw is forgiven (by contrast, it is impossible to imagine public acclaim being given

to, let us say, a bridge that was built at great cost to carry traffic across a river but turned out to be useless because of engineering flaws, even though it looked beautiful). Thus, to some extent architecture is less bound by the insistence on function in the literature on definitions of creativity.

Architectural Education

The history of university-level professional education in architecture is relatively short. Before World War I, the great majority of schools of architecture in the western world were modeled after the French Ecole Supérieure des Beaux Arts, which was founded in the seventeenth century by the Académie Royale d'Architecture. Its main purpose was to serve the needs of French aristocracy. Throughout its long existence, Beaux Arts education promoted the value of historical precedents and the primacy of the great classical traditions. The Beaux Arts educational system was extremely influential and many a school in Europe and beyond followed its tradition and were hence identified as Beaux Arts schools (to distinguish them from schools of other 'denominations'). Leading nineteenth-century American architects went to Paris to study at the Ecole des Beaux Arts. A Beaux Arts diploma was in good currency in the United States well into the twentieth century. Creativity was not a prime goal of standard Beaux Arts education (with exceptions in the last years of its existence); the fostering of creativity and innovation had to await a later major cultural shift. European Beaux Arts schools of architecture were widespread until the 1960s, alongside other types of schools, notably the 'Polytechnic' institutes and schools that reflected the ideology of the Modern Movement. In France the Beaux Arts system was abandoned only after the events of 1968.

An alternative model of architectural education was launched in the 1920s in Europe in two avant-garde institutions, the Bauhaus in Germany and the Vkhutemas in Russia. In both institutions architecture was a unit alongside other units devoted to the arts and to crafts. The foundation of the new schools resulted from novel cultural attitudes and from reforms in education prevalent in contemporary arts, design, and architecture in the aftermaths of World War I and the Russian Revolution. These reforms, which rejected classicism, were strongly motivated by a social and political agenda and by a wish to empower the arts, the crafts, and design through the use of industrial and technological advances. Experimentation and creative initiative were central to the educational philosophy of the Bauhaus and the Vkhutemas, as opposed to the conservative approach of the academies, embodied in Beaux Arts education. Although the avant-garde Bauhaus and Vkhutemas were shut down prematurely due to the political circumstances of the 1930s in Europe, they exerted a lasting influence on architecture and architectural (and design) education. In fact, the term Bauhaus has become an emblem of the modern movement in design and architecture, still in wide use today (and often erroneously replacing International Style).

The second half of the twentieth century has seen a phenomenal growth in higher education, for which the university has become the prime vehicle. Many new universities were founded around the globe. The great majority of schools of architecture, whose number has surged proportionally, operate today as academic departments within universities, sometimes independently but often in partnership with other departments (e.g., planning, construction, environmental studies, engineering, or art). Despite the many differences among schools of architecture and their institutional contexts, almost all of them share similar goals and the programs they offer are based on training principles that were, to a significant extent, inherited from the Beaux Arts and the Bauhaus-Vkhutemas traditions. The omnipresent design studio, central to the curriculum of every school of architecture, is a direct descendant of the Beaux Arts' atelier. Striving for originality and innovation and the legitimization of exploration and search by trial and error have been handed down from the Bauhaus and Vkhutemas, and today creativity is the single most valued capacity students are expected to demonstrate. A similar development is now being seen in technological design education, as well as in other areas such as entrepreneurship education, where creativity is receiving much greater attention as a goal of teaching (as against for instance, mastery of techniques or tools). Accordingly, the role of the studio teacher has evolved: from studio 'master' (or 'mistress'; until a few decades ago, however, architecture was a predominantly masculine occupation and most teachers were men) to what is sometimes referred to as 'coach.' Needless to say, new curricular components have been and continue to be added to professional education to catch up with technological and scientific developments, notably computational options and new building materials, as well as dynamic social and environmental sensitivities and awareness.

Glossary

Collative variables As per Berlyne, are complexity, novelty, surprise, and absurdity.

Concinnity Skillfully put together, well made.

Hedonic Pleasure.

Heterogamous Having different origins, having unlike 'genes.'

Schema Generalized diagram, plan, or scheme.

Semantic Meaningful, as in the meaning of a sentence.

Simulacra Unreal or superficial likeness, an image, or representation.

Syntactic Structural, as in the grammar of a sentence.

Veridical Truthful, corresponding to facts, actual.

Introduction

The 2005 *Compact Oxford English Dictionary* defines art as the expression of creative skill in a visual form such as painting or sculpture (or, for that matter, also music, dance, drama, and literature). Aesthetics is defined as a branch of philosophy and a set of principles concerned with the nature of beauty, especially in art which deals with questions of beauty and artistic taste.

Gustav Fechner's 1876 publication of his *Psychophysics* as the first scientific study of aesthetics began at the point when art styles were still anchored in Renaissance thinking, although radical changes were beginning to manifest themselves. Aristotle's criteria that had defined good art for two millennia as beauty, order, proportion, unity, symmetry, and concinnity, would become virtually obsolete by the end of the twentieth century. Thus, no research on art, aesthetics, and creativity can be considered adequate without taking into consideration the aesthetic theories that have arisen from the artists and art critics, psychologists, and philosophers in the last 100 years.

As a philosophical domain, aesthetics lends itself poorly to the types of quantification that characterize the social sciences. This presents serious problems for the field of cognitive science where Daniel Berlyne placed aesthetics as the empirical study of aesthetic enjoyment and preferences. Redefined as 'Empirical Aesthetics' by Berlyne, aesthetics retains its philosophical foundations although it now includes attention to sampling procedures, research design, and statistical analysis of data. The concomitant hypotheses derive from psychologists, psychobiologists, cognitive developmentalists, anthropologists, information theorists, semioticians, and the philosophical aestheticians themselves.

Over the course of the last 100 years, both art and therefore the field of aesthetics have been completely revolutionized, and since both philosophical and psychological aesthetics must be based on contemporary aesthetic experience, it is necessary to review the changing positions of the visual arts of our time.

Traditional Versus Modern Theories of Aesthetics

The Tradition from the Greeks and Aristotle

The Greeks had no term for 'artist' and no concept of the artist as conceived today. The artist was regarded as a craftsman or

artisan, and the arts were assessed only in relation to the purpose for which they were made. Painting and poetry were 'pleasure giving' arts creating simulacra of real things. The arts were regarded as handicrafts to serve purposes that were approved by society, and the criteria with which to judge such products were concreteness and craftsmanship. The artist's goal was to produce a representation of the ideal in the context of Plato's theory of ideas – to improve on and perfect nature by eliminating imperfections in order to arrive at an ideally beautiful figure according to the 'idea' of the beautiful in the mind's eye. It is evident that the most important goals of the arts in ancient Greece were to mold fashions that would conform with the ideals of the state. The Aristotelian criteria of good art, namely, beauty, symmetry, concinnity, determinate bounds, and above all order and unity in diversity, indicate that the desired response in the observer was to achieve a greater sense of inner equilibrium and balance. The viewer's aesthetic response was an acknowledgment of artistic success – art as spiritual ideal to emulate.

Innovation as Twentieth Century Beacon

The Greek concept of beauty as described by Aristotle remained dominant in Western art and aesthetics until the late nineteenth and early twentieth centuries when the idea of art as a novel and original creation with autonomous criteria specific to art itself became established. This view emancipated the work of art from subjugation to all forms of instrumental purposes, although the Freudian theory of sublimation by means of which libidinal and aggressive impulses are transformed into socially acceptable products bears some resemblance to the Greek aesthetic ideal of the 'improvement of nature.'

Neither the Greeks nor the 2000 years of artists after them entertained a concept of innovation as an ultimate 'good.' However, by the early twentieth century innovation had begun to replace beauty as the criterion of creative worth, and between the First and Second World Wars the Dadaists and Surrealists were particularly determined to burn all bridges behind them. The scientific explosion in knowledge had changed the twentieth century mentality, resulting in a dynamic avidity for the new, the unexplored, and the challenging. Little feeling was left for the traditional or the spiritual. The mood was analytic and

reductive. Ironically, at the same time, there was a need to turn to personal sources as the raw material of artistic creation as the Surrealists did. This tendency continued into the late twentieth century as is evident in Conceptual Art, Body Art, Performance Art, and Happenings.

Innovation and the Avant-Garde

The avant-garde is by definition art that is ahead of its time and is shocking, disturbing, and therefore viewed as socially and aesthetically objectionable. The specific aim of the avant-garde is to undermine the existing order and to replace it by another. It attempts to do this by contradiction, challenge, confrontation, and self-assertion. The avant-garde first defines its distance from the establishment and tries with all its resources to make itself felt as a force aiming to redefine the limits of art. The new art continues to assert itself irrespective of the degree of success or opposition. The criteria for significance are difficult to establish. The novelty and abrasiveness of the avant-garde could never meet the standards of beauty that were the primary conditions of traditional aesthetics, but its own novelty made it readily recognizable as innovation.

Although innovation does not guarantee either quality or significance, it is clear that art cannot be significant unless it is new. However, in order to be recognized as art, the avant-garde product must be seen in context; it is only novel and significant by virtue of the contrast it creates. Confrontation is not always its goal. Sometimes the goal may be to simply direct perception.

Conceptual Art

Conceptualism is the most important of the avant-garde movements to make a radical difference in the evolution of modern art and aesthetics. It came into being when Marcel Duchamp chose a ready-made bottle rack to serve as a work of art. Duchamp's act was conceptual: he deliberately chose an object that had no aesthetic qualities of any kind. This act occurred in 1913, and although the impact of his gesture was immediately felt, 'conceptual art' as such did not become a widespread movement until the 1960s. Duchamp's action opened up the field of art to a multiplicity of gestures that have changed the nature of art – and also the concept of aesthetics.

In America, Joseph Kosuth produced a manifesto for conceptual art describing conceptualism as an inquiry into the foundations of the concept of art stating that "All art after Duchamp is conceptual because art only exists conceptually." Kosuth maintained that if philosophy (and religion) is finished, it is possible that art's viability may be connected to its ability to exist as a pure, self-conscious endeavor, and that art may exist in the future as a kind of philosophy by analogy.

By the 1970s Gregory Battcock maintained that there were no aesthetic criteria for judging conceptual works. The conceptual art framework should be judged by how effectively it changes cultural values, that is, for the ideas that it motivates. Aesthetic theories, as they modulate practice, become the fuel for social significance and a potential for change.

For the most part, however, avant-garde art consists of objects recognizable as art – painting, sculpture, music, dance, or performance – but the aims are different from

those of traditional art in ways that identify avant-garde art as instances of confrontation, challenge, and transformation.

Current Conceptualizations of Creativity

Defined as the raw material of the self, art emerges through the interaction of two levels of ideation: primary and secondary processes. A primary process gives the artist access to the self as raw material – to personal raw drives and desires, libido, and aggression. A secondary process is the transformative level. Colin Martindale identified primary process as essential to creation, changing, however, the terminology to 'primordial thinking' in order to differentiate his theoretical position from that of Freud. Primordial thinking is free associative and undirected thought, thus increasing the probability of novel combinations. 'Primordial thought,' however, says nothing about its deeper 'primordial process' sources. Martindale's term 'secondary process thought' described conceptual thought and according to Martindale, 'It cannot produce novel ideas.' The final artistic product is therefore the result of unsolicited, urgently felt decisions made at the level of primary process and the intentional decisions made at the level of ongoing transformational activity by secondary processes. The primary ideation pumps in new drive material or, as primordial thought, contributes novel associations (in Martindale's terms). Thus, all aesthetic decisions are continually being made by the secondary process as the ongoing input of raw material keeps streaming in at the primordial level, directing the content of the creative process. During the working process, the perceptual – the aesthetic – function provides the crucial contact between what the world will accept and the creator's personal strivings that must be incorporated to effect a work of self-expression in symbolic form. The final emergent qualities of conscious thought direct the execution of the work into a style that is either adapted to the social order or is transgressive of it depending on whether constraints in the personality of the artist have steered him or her toward change and disruption or toward social compliance. In twentieth and twenty-first centuries, artists have felt impelled to create a 'difference' (innovation) and to create transgressive work in order to make an impact on the audience. Thus, the spirit of audacity and rebellion appears to characterize much of the last 100 years of creative work.

Experimental Research on Aesthetics

Daniel Berlyne began the experimental study of aesthetics in the 1960s where Fechner had left off in the late nineteenth century. Berlyne presupposed a basically Darwinian, neutral, monistic theory about psycho-physical relationships between mind, consciousness, and the brain. As a scientist Berlyne was looking for the biological basis of behavior – for variables that lead to arousal of the nervous system. Arousal has been identified as the psycho-physiological energy dimension mediated by activity of the reticular system. Berlyne's psycho-biological theory of aesthetics postulated that the hedonic tone of the stimulus is determined by its arousal potential. The latter is a function of three (and often four) variables as follows: psycho-physical (intensity, saturation, pitch, and brightness),

logical (meaning or signal value), and collative (complexity, novelty, surprise, and absurdity) qualities. The fourth is contributed by nonfocal stimuli. Of the four, the collative variables were seen as contributing by far the largest share to arousal. Like Gustav Fechner before him, Berlyne found that arousal is most pleasant in the middle ranges of stimulation. He also incorporated information theory and therefore described a work of art as an assemblage of elements, that is, information. He was able to show that the pattern of the semantic and syntactic information contained in the artwork could be used to define style. He also made use of multidimensional scaling to obtain indices of stylistic similarity. Berlyne's importance to the field of aesthetics cannot be overestimated. However, he overlooked the reality of the organism as a dynamic and essential component in the response process to aesthetic stimuli.

Berlyne rejuvenated a field that had fallen into virtual oblivion since Fechner's death. He gave it form, substance, and leadership. Aesthetics prospers now as an active field of psychological research largely due to Berlyne's efforts. However, his approach combining information theory with behaviorism may not have been the most appropriate for a study of the effects of the creative process. The behaviorist viewpoint excludes experience and subjective interpretation.

Berlyne's findings have come under increasing attack by Martindale and other researchers in the field of cognitive psychology. Martindale suspected that the arousal system may not be a necessary factor in explaining hedonic responses. Martindale pointed out that formal collative and psycho-physical aspects of the work of art are the ones that people tend to ignore in their search for meaning. Martindale believes that the laws governing aesthetic pleasure are quite similar to the laws governing perception and cognitive processes.

The major drawback to a serious study of art and aesthetics by psychologists has been the absence of a coherent philosophical position of what needs to be studied. Since psychologists have limited their aesthetic research study to the aesthetic response, it means that the study of art as art has been excluded. This makes sense if one focuses on psychology as a study of behavior (the subject's response), as Martindale insisted. But the study is presumably of art and aesthetics, thus, the need to study art as art. This shortsightedness of study is not limited to psychology. University art and philosophy departments have been in the same league. For this reason, questions dealing with the significance of art have been few. To the extent that questions dealing with the significance of art as art and concerns about its importance in a postmodern society have been investigated, it is artists and philosophers rather than psychologists who have done so. But, research by psychologists on cognition and perception as factors in the aesthetic experience has produced some interesting results.

Cognitive Versus Perceptual Theories of Aesthetic Experience

Art as Feeling

Art defined as a significant symbolization and conceptualization of feeling in perceptible forms offers the viewer access to the most basic mode of artistic understanding. The immediate

response is prior to understanding. Feeling must precede in order that the viewer arrive at some understanding of meaning in all areas of human perception. The importance of aesthetic experience has been underscored by stating that what is gained from it is a more basic yet richer form of knowledge than the knowledge typically 'associated with scientific rationality.' The first intuitions of 'knowledge' are affective.

Art as Cognition

In contrast, cognitive theories of art define the aesthetic response in cognitive terms as an inquiry into the 'whole' in order to discover how the parts contribute to the force and integrity of the entire structure. Significance, in this respect, is something that impresses the viewer with its abstract rather than its empathic qualities.

For example, how does one evaluate a work presented by the musician John Cage entitled *4'33"* that consisted of four minutes and thirty-three seconds of silence? Certainly *4'33"* is a novel gesture but how does it qualify as art – that is, as an aesthetic object? For some, it would not qualify at all since it is entirely empty and since it has no qualities we can perceive except the ambient sounds of silence. Nor does it express any feeling; but the thought it provokes is to make the listener think about what music is and is not. In sum, Cage's *4'33"* does fall into the category of avant-garde art by its express intent to call into question what music is, to shock expectations, to change perceptions, and most important, to rethink our own definitions of art. Thus, although *4'33"* does not call out the aesthetic response, it is a major innovative work of twentieth century music.

The preceding issues of feeling and cognition are crucial to an understanding and appreciation of contemporary art and aesthetics. Martindale held that a plausible theory of aesthetics would evolve from what we already knew about cognition and the determinants of hedonic tone, that is, from continuing research in the fields of perception and cognition.

The present status of the research on hedonic response does not allow us to determine conclusively whether a genuine aesthetic response of pleasure derives primarily from the formal qualities of the work of art or from an affective response to the stimulation. Research findings are divided.

Martindale postulated that aesthetic pleasure is related to the net activation of a set of cognitive units. In other words, apprehension of a work of art will activate cognitive units in sensory, gnostic (pertaining to or having knowledge), semantic, and episodic analyzers. The pleasure engendered by the work will be a monotonic function of degree of activation. He underscored the fact that this cognitive model explains only disinterested pleasure. In cases where the arousal system becomes active, it will take over the determination of pleasure or displeasure. Martindale maintained that stronger cognitive units code more prototypical and more frequently encountered stimuli. Whereas sensory and perceptual details would be ignored or quickly forgotten, more abstract concepts would be remembered. In other words, meanings or typicality are more important than psychophysical or collative variables in determining preference. The one exception may be the artists who by profession are trained to be more interested in formal issues and collative variables, that is, in the tricks of their trade.

In 1962, D. W. Gottschalk attempted to deal with the problem of what makes an aesthetic response different from mundane reality processing, by comparing the reactions of naive and experienced (artists) subjects to a work of art. The artist viewers clearly showed a more sustained and critical evaluation, thus reflecting a different interaction with the object.

There is no reason to assume, however, that cognition was the dominant factor in releasing their pleasurable response, although it may have added to the pleasure by virtue of the challenge that synthetic activity presents. R. B. Zajonc clearly indicated that human thinking begins in an intimate association with emotions and feelings which is never lost. Moreover, almost all human activity serves not one but a multiplicity of motives at the same time. It would be difficult to imagine that an aesthetic response would not maintain this intimate contact with emotions in response to a freely chosen complex activity such as looking at art.

Cognitive theories maintain that the perceiver brings together hypotheses, inferences, probabilistic weighting of cues, affective subtleties and associations in response to aesthetic stimuli. Perceptual theories assume that association is the primary mechanism of response. Schema theories (hypotheses, concepts, and categories) belong to the cognitive camp. They place emphasis on constructs as means of explaining the different responses to aesthetic objects. Schemata are essentially information-confirming procedures in which the individual checks a hypothesis aroused by central cognitive and motivational processes against information from the environment. Schemata are relatively stable mental structures.

Julian Hochberg, a veteran researcher in this area, has postulated that internalized mental structures are integral to the perception of pictures. His position was that features of the perceived object indicate what schema would be appropriate to the picture being viewed. The schema is determined by the viewer's prior aesthetic experience or training as well as by idiosyncratic characteristics. The schema gives the viewer a way of storing the results of peripheral inquiries and terminating them when the schema is sufficiently filled out for the task being pursued.

In short, neither the schema nor the perception view of aesthetic experience is able to account for the interactive nature of human behavior in aesthetic experiencing. The more recent contributions are those of information processing. This position regards perception of artwork as inseparable from memory and the representation of information in memory. This makes the response infinitely more complex and unpredictable.

According to R. W. Neperud, the importance of stored information as a factor in directing human attention serves to support the view that the visual and verbal structures that an individual possesses are important constituents, along with the artwork, as to what will be perceived. Thus the emotional bias of visual information may affect not only attention to that material, but also influence, independent of the subject's awareness, the direction of the central processing system.

In short, stimulus and stored information may interact to determine the interpretation of the stimulus, or art. It is evident that an informational processing view must take attentive behavior into consideration, as this is unquestionably an essential dimension of aesthetics. Berlyne's work in the psychobiology of

aesthetics was conclusive enough for Berlyne to sum up his position by stating that:

there are ample grounds for believing that the variables to which information theory has drawn attention have a great deal to do with the motivational aspects of aesthetic form.

Aesthetic experiencing is clearly very complex, and both cognition and affect may be shown to interact in intricate ways. Such experiencing is colored by sources of information about art, by individual habits of information processing, by affect, by past experience, by personal values and prejudices associated with class status, by information about prototypical categories (such as structural properties, subject matter, and constantly evolving artistic forms), and by cognitive structures that provide bases for perceiving the object.

Affect as Primary Variable

Francois Molnar's extensive research led him to propose a science for visual art in which affect plays a crucial part. He made two assumptions as a result of reviewing the field of visual art research. (1) The aesthetic effect is an affective response, a reaction to a stimulus from the outside world, passing through sensory channels. (2) There are no works of art without sensory input. (Note Marcel Duchamp's *Bottle Rack* leading to Joseph Kossuth's "All art after Duchamp is conceptual because art only exists conceptually." The avant-garde strikes again.) An affective response does not exclude the cognitive element. According to Molnar, the first stage of the aesthetic response begins at the retina with the retinal cells responding to the formal properties of the object. The retinal cells act as filters and as feature detectors. This describes the processing of neural information. Molnar adds that sensory information is processed at the cortex only if it is accompanied by influences from subcortical areas. Meaning does not yet exist at the level where the aesthetic response begins. Aesthetic pleasure seems to be independent, at least at the start, of the cognitive system. The aesthetic effect begins at the level of the early sensorial information process.

Molnar believed that one of the most efficient experimental methods to test this theory was to study eye movements because the primary sensory system and the motor system are closely linked. Molnar maintained that the eye does not necessarily seek out the region of semantically rich information. During a fixation, the observer is unaware of the momentary content of the vision. It is therefore not possible to talk about the primacy of cognition in exploration.

The research by cognitive psychologists focusing on cognition versus affect has centered on how individuals attend to, make sense of, and value particular visual phenomena. It has not attempted to look at qualities that define 'art.' The cognitive research can identify preferences for stimuli as well as the contextual variables that affect them. However, this adds little to our understanding of what makes a work of art the profound experience that it is, alive and palpitating to our senses through the centuries, revealing the predominating rhythm of its period. Clearly, affect cannot be ignored and the affective components have been highly underestimated in discussions of art.

The Philosopher's View of Aesthetics

When contemporary philosophers think about art they do not put the emphasis on hedonics. They are concerned with the problems of art in a postmodern society with many opposing views ranging from the dogmatic belief that art cannot be defined to Arthur Danto's statement that art works have at least one necessary condition: that they be enfranchised by art theories. His superb book *'Philosophizing Art'* does a lot to show the way, including his essay "Art and the Discourse of Nations," with "Art is a language in which nations convey so much to one another, that one has to ask how they would do this if art did not exist."

One of the most important and controversial current conceptions of the philosophy of art and aesthetics is George Dickie's 'Institutional Theory of Art' – that is, art in modern Western Culture is what the social group of interested and knowledgeable people (the art world as a social institution) says it is. Yes, his theory is more nuanced and complex than simply "Art is what the art world says it is"; but when you look at the social institution of the art world – the museums, magazines, critics, dealers, collectors, and artists – it is their collective voice (certainly not unanimous but the sound of many voices in conflicted concert) that determines in any time what is considered to be art and therefore worthy of 'aesthetic experience.' As far as the aesthetic evaluation of a given object is concerned, Dickie says the object may be evaluated as good or ordinary or bad, but it is the art world that decides whether to keep it or dump it.

But for those who are more interested in the source of art as a human instinct, Denis Dutton's *'The Art Instinct'* relates art to our evolutionary beginnings in Africa during the Pleistocene Age. Ellen Dissanayake continues the evolutionary anthropological research approach, noting that since the arts and ritual ceremonies have been with us forever, the question becomes why do humans have an irrepensible penchant for making things special, weird, strange, sometimes ugly or extraordinary as for example in ceremonies. In short – why do people 'artify'? She notes that 'artification' has both an adaptive and a functional use, inevitably tending to bring individuals together and thus creating social accord and cooperation. In short, literature and the other arts are devices of orientation. They are vital to personal development, to the integration of individual identities within a cultural order, and to the imaginative adjustment of the individual to the whole larger world in which he or she lives. As Colin Martindale quoted Gregory Feist, "It might perhaps be said that in humans art takes the place of instinct."

Yet, art is there, and "What is it a picture of?" is always a question. The philosopher R. R. Wartofsky said:

The radical epistemological conclusion is that there is no intrinsic, veridical, or 'correct' mode of representation that is not itself a product of the social and historical choices of norms of visual representations. Truth in perception is bound to canons of the veridicality of representation; these, in turn, have a history and are rooted in our social practice and in our own activities of picturing and representing. Thus, it is we who create the very norms of veridicality by our pictorial practice. Such norms are not arbitrary, though they are conventional; they are not biological but historical. Pictures are heuristic and didactic artifacts. They teach us to see; they guide our vision in such a way that the seen world becomes the 'world scene'.

However, Wartofsky's position runs counter to positions taken by psychologists, for example, Hochberg and Molnar, who grounded seeing in the biology of the eye.

Another important concern to philosophers as well as artists is how viewers interpret art. Sidney Finkelstein maintained that all scientific approaches to vision which reduce it to those properties that are shared by all viewers may be distorting the phenomenon they propose to be investigating. Accordingly, the individuality of seeing is irrevocable, and the artist in the process of creating in a highly idiosyncratic and dynamic way makes the individuating decisions. Moreover, it is not clear how and when such decisions and choices are made, but it appears they are made by the intentionality of the artist. This liberty is taken intentionally in the service of expressiveness, and the result is more effective than it would have been had the schema been 'correctly' followed.

This dynamic aspect of looking and seeing is equally applicable to the viewer. It has been shown that the 'scan path' or repeated pattern of eye fixations is particular to a given individual. That is, sense and meaning will vary according to individuals and their histories – their mental 'fixes' and the conditions of artistic representation. Modern visual culture is far from appreciating the many "trans-local and trans-temporal characteristics which give the work of art its unique distillation of a sense of being in the world." Visual form is a way of pointing to feelings, and space is filled with all sorts of motives – and the result is a richness of emergent awareness registered in the course of looking and seeing. Finkelstein underscored the fact that small differences in location and small variations in weight of rectangle, stroke, or color in relation to others give different meanings to forms in the visual field. "What is true of these paintings must also be true of vision itself, but in a larger and more labile sense. Experimental psychologists are not even aware of the need to be sensitive to such poly-referential qualities."

Richard Wollheim gave considerable thought to the significance of art and its nature as the proper study of aesthetics. For Wollheim it was categorically not the organism's response to art, as psychologists since Fechner have maintained, but it is the meaning that is the core of art.

Like Arthur Danto, Wollheim believed every work of art contains specific meanings. In *Painting as Art*, Wollheim presented an account of artistic meaning in four important principles. These were:

1. Each work of art has its own, its one and only, meaning.
2. This meaning is determined by the fulfilled intentions of the artist, where intention is used broadly to refer to the desires, beliefs, emotions, fantasies, and wishes – conscious, preconscious, and unconscious – that cause the artist to make the work as he does.
3. The artist's intentions are fulfilled insofar as the work of art that he felt caused to create, in turn cause in a suitably sensitive, suitably informed spectator the appropriate experiences.
4. The work of art that is the bearer of meaning thus determined is determined in part by its history of production.

Of the four principles, the one which Wollheim felt may be the most difficult to accept was that of integrity, namely, "one meaning and one right interpretation for each and every work of art." To support his position Wollheim stated, "If artists over

the centuries had not succeeded in putting across what they wished to convey, they would have turned to some other activity to transmit what they intended." And yet, it is possible to see that the work which has a one and only meaning can be shot with ambiguity. It is possible to see that it may be layered, and that once these layers are excavated they could all fit together. It is even logical that for historical reasons meanings should be reformulated in order to keep them in touch with new realities.

The multidirectional efflorescence of modern art forms reflects the creative history of their feverish evolution – the mementos of their own hyperbolic time and place. As such they are indices of the bewildering complexity of society's evolution. No real understanding of the art of any time or place can happen without an appreciation of the art's current socially construed history, nor of the 'psychology' which animated the particular time and place, nor of the 'intimacy' of the symbols that described its time. Psychologists, besides perceiving and cognizing, must begin to learn to read artistic symbols as the flesh, blood, and bones of a century exuding the essence of a people's joy, pain, and desperation in a time when nothing seemed impossible.

Art, Artists, and Arts Audiences: Their Implications for the Psychology of Creativity

M S Lindauer, State University of New York, NY, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Art Refers to all the arts (see below) or, depending on context, the graphic arts only, such as paintings.

Arts, the Refers to all the arts, including literary and performing arts, as well as popular art.

Arts audience Includes attendees at theater, dance, and music concerts; visitors to art museum; playgoers; and readers of literature (poetry, novels, short stories).

Big- c and little- c creativity The distinction between the creativity of great art and famous artists in contrast to the

creativity found in everyday activities and among ordinary people, respectively.

Clinical psychology See qualitative.

Humanities, humanistic See qualitative.

Psychology Represented by two approaches to the arts; scientific (see below) and clinical.

Qualitative An approach to the arts that emphasizes the discursive, personal, individual, speculative, and subjective.

Scientific An approach to the arts that is objective, quantitative, methodological, and empirical.

Introduction: The Larger Context

Art is undoubtedly a creative achievement of major importance, dramatically demonstrating what it means to be human and offering a unique perspective on mental life, emotions, attitudes, relationships, and behavior. Art is therefore prototypical, a significant sample, revealing a wide array of psychological phenomena, and additionally, a means for personal fulfillment and a source of individual pleasure. An integral part of human experience, art parallels, reflects, and influences people, society, and culture. For good reason, art and artists are synonymous with creativity. Psychology is therefore well advised to consider the relationship between art and creativity.

A substantial body of psychological literature, in fact, does address artistic creativity. In this article I examine its overlap with creativity in general, the important topics and issues it addresses, major findings, and some general directions for future research. My focus is on the scientific approach to the psychology of creativity, although I touch on psychoanalytic and related perspectives, and to a lesser degree, social and other broad influences that facilitate or restrict artistic creativity. Largely ignored, though, is artistic creativity across cultures, including non-Western examples, where artists are often anonymous and credit for creative works is not assigned to individuals. The full story of artistic creativity is embedded in a larger matrix of historical, intellectual, professional, and market forces.

Key Topics

Why Study Artistic Creativity?

Aside from its bearing on creativity, art dramatically illustrates a wide range of psychological phenomena, ranging from the personal, cognitive, and developmental to familial, social, and interpersonal. Art also provides the materials with which to study psychological topics, including aesthetics (creative works as beautiful) and aging (the old-age style of late-life creativity). The empirical study of art is also an interdisciplinary bridge

between science and the humanities. In addition, research on art has the potential of challenging psychology by pointing out omissions in coverage and suggesting alternative interpretations of established findings.

With respect to creativity, great art and recognized artists illustrate its highest level, and in nonartists, too, when they reacting to art with new ideas and revelatory feelings. The content of art and the lives of artists, furthermore, suggest ideas about creativity to be tested and provide the materials with which to do this. Artists and arts audiences also serve as research participants in studies of creativity. Furthermore, psychologists who are open to art, the writings of scholars, and the biographies of artists bring new viewpoints to established assumptions and accepted interpretations of creativity based on investigations of nonartistic materials with participants in neutral settings.

Research on artistic creativity can be done for non-utilitarian purposes, as an intellectual exercise, and also for practical reasons: selecting creative people, usually through tests; improving the educational curriculum; training leadership in businesses and organizations; determining the kinds of audiences attracted to the arts; contributing to an understanding of the relationship between creativity and psychopathology; and using drama, paintings, and literature in art therapy. Furthermore, whatever is learned about artists of renown and works of art that revolutionized the field (Picasso and Cubism, the Impressionists and the use of light) – so-called big-C creativity – is applicable to ordinary people in everyday circumstances, like raising children, or small-c creativity. Big-C creativity reflects the highest and most obvious instances, though, which makes it clearer and easier to specify than little-c creativity in developing theories and doing research.

Definitions

References have been made to art, artists, and arts audiences, as well as psychology and creativity, as if their meanings

were straightforward. But these terms resist easy definition. Nonetheless, a start must be made, for who and what about creativity is studied determines interpretations and explanations of creativity.

Art, artists, art audiences

1. *Art*: Art is a collective term that includes paintings and literature, photography and cinema, opera and plays, architecture and the performing arts, and both their high (classical) and low (popular) forms. Given this diversity, the question of what is art is a perennial one. Consequently, a great deal of contentious debate centers on whether art means something different for everyone, who decides on what is art, and if more or less anything can be called art. These issues concern philosophers, like Nelson Goodman, and most recently Dennis Dutton in *The Art Instinct*.
2. *The artist*: The definition of artist is also neither precise nor fixed, resulting in considerable uncertainty over who is an artist, what artists do, and for whom they do it. However artists are defined – and whatever art is – they make art and the public generally appreciates it.
3. *The arts audience*: The creativity of artists and art seem more self-evident than the case for arts audiences. The experience of concert- and play-goers, attendees at art museums, and readers of literature is occasionally unique, profoundly emotional, often thought provoking, and perhaps life-changing, all of which can be considered creative. Consider, too, the parallels between artists and viewers of paintings, listeners to music, observers of dance, and readers of poetry. In both practitioners and spectators, aesthetic sensibilities are engaged; imagery and imagination are aroused; fresh ideas, deep feelings, and novel ideas are triggered; and thinking and behavior are redirected or modified. A further parallel: just as art is a specialized endeavor and artists small in number, relatively few people appreciate the arts, attend arts events, read literature, and even fewer could be called esthetes or aesthetic. In addition, audiences engaged with the arts, like the heightened sensitivities of artists, are a special filter through which to understand creativity. Most importantly, without an audience for the arts, art and artists might not exist, at least as we know them today, and our views of creativity would be quite different.

Creativity

Definitions of creativity vary considerably, initiate fierce discussions, and arouse controversy. Consider the different kinds of creativity suggested by synonyms such as these: genius, 'giant,' (near) great, master ('the master'), exceptional, (super) star, talented, polymath, gifted, and (highly, very, unusually) original. Then there are autistic savants, creative in one area and sub-par in others. Mention has already been made of big-C creativity (the greatest artists, the masterpieces) and little-c (everyday) creativity, a distinction that leads to another tough question: Is everyone creative, at least to some degree? Accordingly, creativity is normally distributed but varies in amount. Democratizing creativity this way makes it congruent with

critics who see art as elitist, class-based, ethnocentric, and more (removed from the people, marginalized, nonparticipatory, uninvolved with the community, exclusionary, and directed to wealthy, older, and white patrons).

Problematic for defining creativity, too, are the many ways in which it is expressed. Painters, novelists, and musicians differ in obvious ways. Nonetheless, we usually assume the process is similar among artists, as well as in creative scientists, inventors, engineers, and other nonartists. If true, then painters, composers, and authors – compared to less creative nonartists – should more readily recognize, accept, and appreciate scientific and other kinds of creativity (painters' views on modern poetry, artists on the latest technological achievements) and vice versa (scientists on contemporary art). This prediction, as far as I know, has not been tested.

More certain are descriptions of creative works of art (or creative anything): they are of high quality (exceptional, outstanding, the best); original (inventive, new, novel); appropriate (useful, relevant); communicated; accepted (eventually if not immediately); persisting over time; and influential. Creative outcomes, all concur, are not derivative, an elaboration or extension of something developed by someone else at an earlier date. Substantial agreement also exists on descriptions of creative people, which are quite extensive (listed later) and include many of the same terms applied to creative works (original, nonconformists). Places, too, are called creative (a classroom), as are historical periods and societies (the Golden Age of Greece, Renaissance Florence).

Psychology

Psychology, too, is not a term with a single meaning, and each takes a different approach to artistic creativity. Qualitative orientations are represented by Freudian (psychoanalytic), Jungian, Rankian, and psychodynamic positions with clinical and therapeutic preoccupations. In depth narrative analyses are applied, for example, to creative writers (Dickinson, Melville, O'Neill, van Gogh, Virginia Woolf, and especially Shakespeare). Scholars, critics, and historians often incorporate these interpretations into discussions of artists and art.

Quantitative approaches to artistic creativity, also known as the scientific, empirical, objective, experimental, and academic, and emphasized in this essay, fall under several headings. The psychology of art (or psychology of the arts) and the psychology of aesthetics (psychological aesthetics, the psychology of aesthetics) focus on the importance, role, correlates, and effects of art. Most rigorous, precise, and criticized (for its reductionism) is experimental aesthetics. With roots in philosophy, it translates the concepts of beauty, pleasingness, harmony, and many other qualities (balance, rhythm, liking, preferences, attractiveness, appeal, satisfying, 'good') into simplified and hence manipulable and studiable laboratory surrogates (color patches, sounds, and syllables for paintings, music, and literature, respectively). Cutting across these approaches is the psychology of literature, of music, of paintings, and so on, and research that concentrates on the artist, the work of art, and the audience for art. Mention should also be made, from an historical perspective, of Gestalt psychology, an early school of psychology that gave serious attention to the arts.

Background and Approaches

Background

Creativity is a relatively new topic in psychology. Even though Freud published *Leonardo da Vinci and a Memory of His Childhood* in 1910, and *Creative Artists and Daydreaming* in 1908, scientific attention only began around 1950. Important advances in research and theory have been made by a number of psychologists. (A short list includes Teresa Amabile, Mihaly Csikszentmihalyi, Howard Gardner, Howard Gruber, J. P. Guilford, Kay Redfield Jamison, Donald MacKinnon and members of the Institute of Personality Assessment and Research he headed (including Frank Barron and Ravenna Helson), Colin Martindale, Anne Roe, Albert Rothenberg, Mark Runco, Keith Sawyer, Dean Simonton, Robert Sternberg, E. Paul Torrance, and Robert Weisberg.) Textbooks, books of readings, and handbooks on creativity have been published; and studies and essays are found in the *Creativity Research Journal*, *Journal of Creative Behavior*, *Leonardo*, *Poetics*, and *The Psychology of Aesthetics, Creativity, and the Arts*. Division 10 of the American Psychological Association (Society for the Psychology of Aesthetics, Creativity, and the Arts) specializes in the areas noted in its title. The International Association of Empirical Aesthetics, concentrates on aesthetics and art, and publishes *Empirical Studies of the Arts*. Scientific literary studies are promoted by IGEL, the German abbreviations for the International Society for the Empirical Study of Literature.

Approaches

General

Creativity can be approached in one of two general ways. One is 'from above' (big-C creativity), where the focus is on outstanding artists, great works, and reactions to recognized art. The alternative is creativity 'from below' (little-c creativity), which studies ordinary people and general psychological processes, often in the laboratory or other kinds of controlled settings. Generalizations about creativity can therefore flow in either direction: up, from 'below,' or down, from 'above.' Similarly bidirectional is the application of the concepts, methods, and models of psychology to artistic creativity, or alternatively, the translation of the writings of art historians, musicologists, literary critics, artists, and other experts in the arts into psychological terms that are studied with traditional scientific methods. Rarely are the arts approached from both above and below simultaneously, in parallel fashion, or sequentially. The topic is too complex.

Psychoanalytic

The psychoanalytic and allied approaches to creativity (e.g., Jungian) are the most well known, endorsed, and criticized. The focal point is the individual and his or her personal experiences, especially their unconscious origins and disguised manifestations. The Freudian view is that a work of art is therefore an unconscious, symbolic, and indirect manifestation of an artist's repressed wishes from childhood, usually sexual in nature. These creative forces are known as primary processes, in contrast to secondary processes, which depend on conscious skills that apply an approved veneer onto baser urges. Creative output is therefore a sublimated defense mechanism that

protects artists from being overwhelmed by childhood anxieties. Audiences can then safely project their own camouflaged traumas of infancy onto socially approved artistic products. Creativity is therefore, in a sense, biographical for both artists and audiences. While some psychoanalytic concepts have become part of mainstream academic scientific psychology (the subliminal, or un verbalized material below the threshold of consciousness) the reverse is less often the case.

Scientific

The scientific psychological approach to creativity applies the standard array of empirical research tools to works of art, artists, and audiences: testing (psychometrics), correlations, experiments, cross-sectional and longitudinal studies (studies take place at a single time or over an extended period, often years, respectively), interviews, case studies, and the content analysis of biographical, archival, and written material (the historiometric method). These methods yield information on the personality of creative people (autonomy, openness to experience); cognitive abilities (problem-finders/definers/solvers; stimulus free rather than stimulus bound); development (usually emphasizing the younger years); social characteristics (attitudes, values); and interpersonal relations (most often involving family relations). Examined, too, are individual differences, distinctions between minority groups, and gender (e.g., creative men and women face and overcome different demands).

Scientifically oriented psychologists also investigate innate determinants of artistic creativity in biology (genetics, heredity), sociobiology and evolution (the random variations that facilitate survival), and neurophysiology (sensory, affective, and verbal areas of the brain). Neuroaesthetics, a recently coined term, is the scientific study of the neural consequences of contemplating a creative work of art, such as the involvement of the prefrontal cortex (in thinking) and limbic systems (for emotions). Physiological accounts locate creativity and its underlying correlates but do not tell us what creativity is, what it does in relation to self, others and society, and in whom it happens, why and when. These questions are more germane to experientially and behaviorally oriented psychology. Mathematical models of creativity, such as chaos theory, address other sorts of questions.

The broadest approach to creativity places it within social, cultural, economic, political, and historical contexts, where one might find references to art as reflecting national character, a nation's values, and a people's 'spirit.' The emphasis is on the controlling roles of institutions, corporations, markets, ideology, laws, censorship, and other sources of power, the gatekeepers. Related topics are the means of communication (critics, dealers, collectors); the art community (the relation of artists to one another, now and in the past; the New York City environment); the receptivity of different kinds of audiences, such as teenagers; the importance placed on the artist's self versus others; the artist as teacher and entrepreneur (merchant, businessman); and most simply, the need for artists to earn a living. In contrast to psychological approaches, broad approaches to artistic creativity are centered on external agents (collectors, philanthropists, patrons, critics, mass media, reviewers, curators, and museum directors) who facilitate or stultify creativity.

What Has Been Learned?

Psychology has learned a great deal about creativity, both artistic and otherwise, only a small part of which can be touched upon in the limited space available here. Much is known about the personal characteristics of creative people: they are tolerant of ambiguity, risk takers, solitary, persistent, hardworking, versatile, consumed by their work, and driven by intrinsic rather than extrinsic motives (doing something well for its own sake rather for rewards). A great deal of attention is also given to the cognitive characteristics of creative people. They diagnose a problem; conceptualize, reconstruct, redefine, and redirect their thinking; and generate, synthesize, invent, and extend their ideas on how to proceed. Creative thinking is also described as putting the artist or audience member into a state of 'flow,' where the engagement with art is so intense as to make one oblivious of external events.

Within the cognitive realm, too, an important distinction is made between convergent and divergent thinking. The divergent thinker (related to oppositional, bisociational, and Janusian modes of thought) is characterized by having many possible answers to a problem while the convergent thinker looks for the one right (or best) answer. Creativity favors the divergent mode, although convergent thinking is also necessary, for instance, in learning, remembering, and applying rules, techniques, conventions, and skills. Thus, a single flash of intuition, a hunch 'out of the blue,' is not enough but has to 'fit the facts' and meet certain requirements. Thus, convergent and divergent modes operate jointly, or one or the other may be ascendant at different times in the creative cycle.

Intelligence plays a somewhat uncertain role in creativity. For example, how high an intelligence is needed for artistic creativity, compared to scientific creativity? And does it have to be high at all (whatever 'high' means)? Several kinds of intelligence have also been proposed (eight so far), some more applicable to different areas of the arts than others. Thus, visual-spatial intelligence is critical for artists, musical intelligence is necessary for composers, verbal for writers, and kinesthetic for dancers. The different kinds of intelligences work together. For example, dancers have to rely on musical intelligence when performing with an orchestra, and interpersonal intelligence is needed in working with other dancers, the choreographer, and various stage personnel.

Creative works of art have also received considerable study. A major and sustained project is plotting the years in which creative output ascends, peaks, and then declines for different kinds of artists, and artists as a group compared to others, like scientists and scholars. A related topic examines changes in creative expression with age, such as the old-age style, which some interpret as a sign of renewed creativity rather than an indication of loss. These and other areas of study and findings in the study of creativity, in general, are covered in the many chapters that make up the volumes of this encyclopedia and its previous edition.

Indeed, some complain of too many facts about creativity, artistic or otherwise, and not enough coherence between them. Several heuristic devices help organize the abundance of information. An early but still useful classification refers to the stages of creativity: preparation (studying, reading); incubation (silent or unconscious thinking); illumination

(insight, clarification); verification (checking the validity of the idea, working out the details); communication (insuring that breakthroughs are understood by others); and acceptance (promoting, networking). Another helpful framework speaks of the '4 Ps' of creativity: person, product, process, and press (the environment). Useful, too, are the '7 Is' of creativity: inspiration, imagery, imagination, intuition, insight, incubation, and improvisation. Constructive as well is an emphasis on certain key features: fluency (number of different responses); flexibility (variety of responses); originality (of the responses); and elaboration (developing and adding details). An interesting model speaks of the two cycles of creativity: generative (of ideas, possible solutions, research possibilities, trial and error) and explorative (testing and evaluating). Another distinction is made between artists who are conceptual (Picasso, Matisse, Warhol) or experimental (Mondrian, Kandinsky, Pollock). The former did their greatest work suddenly and early in life while the latter changed gradually later in life. A provocative notion divides artists into those who have a rough idea of what they want to accomplish, which propels them in a certain direction; and others who 'fiddle around' until they stumble onto something they like or satisfies them. A similarly broad perspective categorizes artists into those who work within the current paradigm but extend, elaborate, or develop it; another group rejects current models and finds its own way; and a third set that falls between the first two in attempting to integrate the old with the new.

Issues

Much is known about creativity and the arts, and a variety of approaches, conceptions, and models seek facts and ways to organize them. Nonetheless, a number of important issues remain unresolved in understanding artistic creativity.

Is Artistic Creativity Scientifically Studiable?

Probably the most basic issue is whether the scientific study of artistic creativity is possible. Art is, by definition, subjective, unique, and individualistic while science is objective, general, and abstract. How is rigor possible where imagination reigns supreme? How much sense do statistical accumulations make when our interest is in a particular work, a specific artist, or a personal response? Scientific studies, by their nature, aggregate artists, works, and observers/listeners/readers, resulting in bland generalizations, characterless and without identity. The inherently conservative canons of science stand in sharp contrast with the revolutionary, avant-garde, and nonconforming world of art. Can individual and general interests be integrated? The distinction, generally known as the ideographic (the particular) and the nomothetic (the universal), respectively, arises when individual differences are focused upon, as is often the case with personality. Ideally, specific and general aspects of artistic creativity should be investigated simultaneously, an Herculean task that becomes Sisyphean if societal and similarly broad determinants are also factored in. One partial solution is to use particular examples of art and anecdotes about artists to illustrate anonymous generalizations. Another option is to study one artist

(Shakespeare, Mark Twain) or one work (Picasso's *Guernica*, Darwin's notebooks) in depth, using multiple measures.

Needless to say, there are also significant similarities between art and science that need to be kept in mind. Like artists, scientists rely on intuition (hypothesis), seek order (through numbers and statistics), and struggle for meaning (with theories). Furthermore, given a choice among several equally possible explanations, scientists select the one that is 'elegant,' 'good,' 'right,' simple, pleasing, and beautiful – or in a word, aesthetic. Scientists and artists also rely on imagination, persistence, and other personal traits and cognitive abilities that spur curiosity and satisfy a need for sensibleness. Bear in mind, too, that some artists of renown, like Leonardo, were also eminent scientists. Not unusual are scientists with considerable artistic talents (Einstein, physicist and violinist; C. P. Snow, who first penned the 'two-cultures conflict,' physicist and novelist). The two disciplines, moreover, rely on the abstract, and increasingly so in the history of art with the advent of modernism. Picasso and Braque, it is said, developed cubism in order to explore the possibilities of pictorial space.

Are There Different Kinds of Creativity?

Picture a novelist, playwright, poet; think of literature, music, architecture. How could this diverse range of practitioners and practices reflect a single model of creativity? Each domain has, at least to some degree, different origins, pathways, and talents. Nonetheless, a general underlying creative process seems reasonable, along with differences in artistic expression specific to each medium. The issue then is specifying the identities and contrasts, the dimensions on which they lie and how much of one or the other.

Differences between creative artists are related to the question of differences between artists as a group and creative non-artists (scientists), and between creative and minimally creative people. Here again, in a similar guise, is the distinction between big-C and little-c creativity, which in turn is embedded in an even larger question touched on earlier: Is creativity universal, an integral part of human nature? As if concentrating on masterpieces, famous artists, and aesthetic people were not difficult enough.

These questions become irrelevant, though, for those who maintain there is no such thing as creativity. People do creative things not because they are creative but because they are skilled, adept in certain techniques, follow the necessary procedures, extensively trained, dedicated to practice, endowed with a beneficial genetic endowment, and blessed by a supportive family and environment. In rebuttal: How account for so many not becoming creative artists (or creative anythings) with similar genetic, personal, familial, and environmental advantages? The answer may reflect a difference in motives or attitudes: "I am (or will be) creative." "I am determined to do great things." "I will make a name for myself." Whether such decisions move the individual toward actually becoming creative may depend on a string of fortuitous external events (the 'breaks').

A less radical position places creativity within an already established field of psychology, rather than as a relatively separate and distinct subject, as is currently the case. Accordingly, some put creativity within the framework of ordinary

thinking, an extension of everyday cognition. But relocating creativity leads to new problems. If equated with problem-solving, for example, who sets the problem, the individual or external circumstances? A problem may arise when an artist wants to do something different from earlier work or because she is competing with another artist. Further, what happens when there is no problem to be solved, as when a creative person is just 'fooling (or playing) around,' enjoying himself, curious, or simply lucky? Also, how account for spontaneous solutions to unexpressed problems? "It just came to me, I don't know from where." When creativity is dispatched to another area, whether to cognition, personality, or development, new and unforeseen difficulties emerge. In addition, when creativity is submerged within another area of psychology, some might say it loses its special cachet.

Who Is Studied?

Progress on many of the issues raised above depends on who is studied. Often, the sample is based on convenience: undergraduates, children, patients in therapy, the institutionalized. And what are we to make of individuals who sincerely believe they are creative but no one else does (except perhaps their mothers)? Relatively few studies, moreover, recruit artists, and even fewer are eminent or recognized as creative by experts (historical figures are the exception). Creative people are most often selected on the basis of high scores on a creativity test, of which there are several differing in structure and rationale. Unknown is whether research participants drawn this way are actually creative outside of the testing room, representative of little-c creativity, or future exemplars of big-C creativity.

When studies are limited in the ways described above, artists, scholars, critics, and the public at large judge them as irrelevant and trivial. Smacking of scientism, too, are investigations that add a smidgeon of data, show off a new technique, or cleverly retest an old idea. Off-putting, too, is the misuse of correlational findings, as when an outstanding trait of creative people (say independence) is used to explain, predict, or foster creativity in others.

What Is Studied?

What about artistic creativity is studied? The focus is usually on cognition, personality, or some other process like motivation. Much less attention is paid to what artists actually do, the work itself, and what makes it creative. Yet it is the creative end-product that ultimately matters; it has an impact, makes a difference, changes things. Creative outcomes are original; the individuals who bring them about are, in the final analysis, secondary.

Neglected as well are judgments of what it is about a work that is special, unusual, or creative, either by experts or non-artists. How is it perceived? What stands out? Are feeling or thoughts evoked? To illustrate my point, let's say authorities advise visitors to an art museum that a work or an artist is creative. Would they agree, be indifferent, 'go along,' or laugh up their sleeve ('a chimp can paint just as good'). To the distress of connoisseurs, the proverbial man (or woman)-in-the-street, prefers 'pretty pictures,' mass-produced kitsch, Elvis

Presley portraits on silk, big-eyed children, or portraits drawn by street artists for \$10 (\$5 extra for color). Surveys never ask, as far as I know, "If money were no object, would you buy this Rembrandt/boxed CDs of Beethoven's sonatas/complete set of Shakespeare's works/a season's subscription to the opera/theater/ dance?" Investigations and discussions of artistic creativity should, to be complete, consider people's actual reactions to what others call creative (or art).

The public also holds some strong opinions, some would say myths, about creative artists (often shared with artists themselves). They are alienated recluses, Bohemian, starving, working in obscurity (in a garret), suffering (tubercular), overly sensitive, rejecting worldly success, divinely inspired, engaged in a sacred pursuit, and slightly mad. The extent of these beliefs should be empirically investigated. For example, are they correlated with attendance at arts events?

When Is Creativity Acknowledged?

Herman Melville died unknown. Keats, dying, wrote "Here lies one whose name was writ in water." Stravinsky's *Le Sacred du Printemps* provoked a riot of angry concertgoers. Numerous historical figures, once considered creative in their time, no longer are (see older editions of encyclopedias). The time-bounded nature of creativity is also illustrated by childhood prodigies who did not fulfill their early promise, and brilliant young artists who failed to live up to their potential (while others surprised their teachers).

Shifts in the recognition of creativity, at least in part, depend on a paradox. Creative work is novel in relation to what is known and accepted. Eventually, creative breakthroughs become known and accepted. Subsequently, and inevitably, they are superseded by more recent creative achievements. Creative work therefore takes place in a fuzzy zone, somewhere between the familiar and unfamiliar, the recognizable and unrecognizable, the identified and the unknown. Revolutionary efforts fall outside the traditions of a particular time, 'on the edge,' and if too far out they are deemed unacceptable and rejected.

At What Age Does Creativity Emerge?

For Freudians, the source of creativity is planted very early, before age five or so; the rest is destiny. Creative forces then blossom in adolescence or early adulthood. Others argue that creativity evolves and appears relatively late in life. For example, Freud, Darwin, and George Bernard Shaw did their major works in middle age or later (although they displayed their talents earlier). Van Gogh is a famous case of a late starter. An extended developmental perspective on creativity focuses on the age at which individuals realized their special gifts, how they felt about them (superior, accepted, resentful?), and why certain professional paths were chosen over others when abilities lay in more than one area. These kinds of questions are addressed by systematic studies of early records – letters, sketches, notebooks – for events that foreshadowed later accomplishments.

Are Interdisciplinary Exchanges Possible?

Psychologists in general are not especially acquainted with the arts or particularly well read in the humanities. Likewise,

scholars in the humanities are not versed in the scientific method and its technicalities; artists are even less proficient in such matters. The temperaments attracted to these disciplines sharply differ, not to mention their dissimilar training and goals. This insularity can only become worse as professions become increasingly more specialized and narrow in scope. The 'two cultures conflict' is not an easy barrier to overcome. A few figures, though, E. H. Gombrich in art history and Rudolf Arnheim in the psychology of art, to name just two notable individuals, successfully integrated their knowledge of scientific psychology, the arts, and the humanities. Interdisciplinary crossings are therefore possible and more likely to occur, at least among psychologists, as they delve into art and art history through research on artistic creativity. Their journeys tangibly demonstrate the fruitfulness of interdisciplinary links, and make it harder for scholars and artists to ignore the results of such crossovers.

Creativity as Health or Pathology?

Creativity is associated with health, self-fulfillment, and problem-solving but also with mental illness (the 'Sylvia Plath effect') and at least historically, with criminality, with which it was believed to share the same genetic sources, albeit with more benign consequences. Creativity therefore reflects both the bright and dark side of human nature, its healing and suffering aspects. Falling somewhere between these extremes are views of creativity that see it as eccentric, unpredictable, contrarian, and mystical. Contradictory notions about artistic creativity need to be made explicit, recognized, and clarified.

The Morality of Artistic Creativity?

Deserving some comment, too, is the uncertain relationship between artistic creativity and morality. Artists argue for complete freedom to do their work, to go their own way, no matter how outrageous, odious, and upsetting it may be to others. Scientists, too, grapple with the consequences of their work (developing the atomic bomb, for example) and whether the ends to which their works are put should be their concern or consigned to politicians. Artists have resisted this sort of self-scrutiny and therefore continue to come under attack for anti-social rebelliousness.

Future Research

Studies of creativity would do well to include art, artists, and arts audiences, and to conduct investigations in artistic venues, like concert halls, possibly during intermissions, at the end of performances, and with mail-in questionnaires. If psychology's research agendas are dominated by traditional and familiar practices, they will remain blind to the possibilities offered by the arts. Refreshingly new points of view are likely to emerge if historians, literary critics, and artists are listened to carefully and read conscientiously. Investigators should also become more acquainted with creative artists through interviews, case studies, and historical sources; be open to guidance from experts when selecting works of art to include in studies and

when interpreting the results of such efforts; and serve as participant observers in book discussion groups, at gallery openings, and other artistic settings. Psychologists may find that artists, scholars, and arts audiences are not as concerned with the same problems as they are (the sources, development, and trajectory of artistic creativity) and instead are preoccupied with what's 'hot' and who's 'in,' predicting changes in artistic style, and puzzling over the millions spent for a single work at art auctions. Artists may indeed mull over the origins of their creativity – or agonize over critics' reactions; scholars might very well scratch their heads over what makes a work of art creative – or how it differs from previous efforts; audiences at a musical concert relish their aesthetic experience – or vainly search for a comprehensible melodic line. In other words, psychologist should pay more attention to the real art-world.

For example, arts audiences may wonder whether exposure to the arts affects their creativity (or their children's) and in what ways. Do new ideas arise, are dormant feelings aroused, and will previous ways of thinking and behavior be nudged in new directions? Further, will some become active participants (join the stage crew at a community theater) or develop an artistic hobby ('Sunday painters,' take up the piano)? Amateur artists, although large in numbers, are a neglected segment of the art-scene, falling somewhere between professional artists and casual consumers of the arts. The study of amateur art and artists might therefore clarify the relationship between little-c creativity and big-C creativity.

Conclusions: The Reciprocity of Knowledge

A great deal is known about artistic creativity, although a number of critical issues, discussed above, need to be explored further. Unresolved matters, however, should not mask the substantial contributions scientific studies of artistic creativity have made to psychology. They are also a counterweight to Freudian analyses that dominate discussions in art history and the humanities in general. Masterpieces do not arise solely from the unconscious and artistic genius does not necessarily spring from repressed childhood experiences. Empirical studies, too, liberate artists by increasing their awareness of the cognitive nature of art-making. Arts audiences, too, benefit from objective knowledge about the benign origins for the pleasures of art.

The typical modes of scientific analysis are rational, deductive, precise, logical, and mechanical. These are balanced by inquiries into what it means to be a creative artist and to experience an artistic work with an emphasis on intuitive and empathic thinking and sensual and expressive feelings. Prominent, too, are introspective, experiential, and phenomenological self-reports, interviews, case studies, historical information, and autobiographies. Research materials are also expanded by the inclusion of novel visual forms (paintings), complex sounds (music), complicated verbal texts (literature), unfamiliar movements (dance), and subtle tactile information (sculpture). Expanded, too, are the populations studied (artists) and the settings for research (in art museums). The widening of research methods, materials, and locales are refreshing antidotes to the artificial, simplified, and isolated limitations of the typical psychology laboratory. Consequently,

psychology's boundaries are extended, researchers' technical skills are sharpened, and theorists' conceptual frameworks are stretched, not to mention the addition of fascinating topics to study.

The unfettering of traditional research paradigms is not without its perils, though, such as managing the subjective vagaries of self-reports. The advantages gained by studying artistic creativity comes at a price and psychologists are hard pressed to use their ingenuity in applying the scientific canon correctly and meaningfully. The challenge of resolving the inevitable difficulties of investigating sublime phenomena requires psychologists to be, in a word, creative. But the effort is worth it, especially since artistic creativity adds a welcome facet to positive psychology, neglected until recently.

Summing up: The psychology of creativity is advanced by the study of art, artists, and arts audiences. Conversely, writers, painters, composers, and other practitioners of the arts profit from scientific psychological studies of artistic creativity, as do literary critics, musicologists, and scholars along with readers of poetry and other kinds of art audiences. Competing approaches to artistic creativity, the multitude of undigested facts, the challenging issues that arise, and the increased opportunities for research sketched in this review should stimulate new thinking, some of it hopefully creative. Important questions about artistic creativity – say, unexpected changes in styles of painting or literary expression – are less tantalizingly distant than they initially seemed.

Associative Theory

S W Russ and J A Dillon, Case Western Reserve University, Cleveland, OH, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Associative theory An explanation of creative thinking as the process by which disparate elements come together in new combinations for a useful purpose.

Brainstorming A technique for producing a large quantity of ideas while postponing judgment on the quality of the ideas.

Convergent thinking Thinking that brings together information focused on solving a

problem, especially problems that have a single correct solution.

Divergent thinking The ability to generate a variety of associations to a word or solutions to a problem.

Incidental learning Unplanned or unintentional learning in which ideas or relationships previously seeming to be irrelevant are later associated.

Historical Foundations

Associative theory holds that creative ideas occur when disparate elements come together to form a new idea or solution to a problem. There is a general consensus in the field today that having a broad search process that enables a variety of associations to occur helps creativity. The importance of broad associations in the creative process has been a central component of several theories of creativity which will be reviewed in this article.

The associative theory of creativity explores the ways in which ideas or solutions to a problem might be generated and how those ideas are linked together in the mind. Historically, a variety of philosophers, scientists, and psychologists have pondered and researched the importance of associations in the creative process. Associationism was first a philosophical idea asserting that mental processes operated by the association of one state with its successor states. British associationists including John Locke and David Hume maintained that this principle applied to all mental processes. Ideas were said to be associated in the mind according to certain laws including contiguity and resemblance. Ideas could therefore lead to further ideas and this served as the understanding of mental functioning in general.

Alexander Bain wrote of the idea of incubation, when new combinations of elements can sprout from that which is already in an individual's mind. One can imagine already existing ideas in a person's mind, free-floating and continuously bumping into each other and combining. Sometimes, ideas will combine in ways that are not new, useful, or of any particular interest; however, other combinations may be a unique or novel solution to a problem, and grab the attention of the individual, such that the idea becomes conscious and is recognized as creative. Similarly, Albert Einstein spoke of 'psychical entities' which made up thoughts and how the combining of these elements was the 'essential feature of productive thought.' Such perspectives on the importance of combining already existing elements in new ways can be viewed as the influential precursors to associative theory.

Mednick's Associative Theory

In 1962, Sarnoff Mednick published his associative theory of the creative process, stating that creative thinking was the process by which disparate elements come together in new combinations for a useful purpose. A creative solution to a problem comes about by bringing together multiple ideas which only when combined in a new way become useful as a viable solution. A combining of more remote elements is viewed as more creative than the combining of more similar items. For example, the Beijing National Stadium known colloquially as 'the Bird's Nest,' designed for the 2008 Beijing Summer Olympics, addressed the need for an original stadium with the model of a nest, thus bringing together two remote concepts into one creative product.

According to Mednick, a person can produce creative solutions through any of three separate processes: serendipity, similarity, or mediation. A creative solution stems from serendipity when associative elements are evoked by a person's situation and are accidentally put together. Accidental discoveries, such as when US Navy engineer Richard T. James accidentally knocked a spring off his work table and invented the Slinky, are considered serendipitous. A creative solution might also be produced through similarity, such as when associative elements are evoked because of their similarity to another element, such as with words that rhyme. Lastly, creativity might arise from the process of mediation, in which associative elements are evoked through the mediation of a third common element. In other words, there may be two associative elements which appear unlinked until a third mediating element is presented at which point the association becomes clear. For example, a medical diagnosis might serve as the mediating link between multiple symptoms which would otherwise appear unrelated.

Mednick identified a variety of variables that could contribute to the likelihood of someone coming to a creative solution or making a novel association, with a strong focus on individual differences. Each is discussed below in more detail:

1. the need for associative elements;
2. an individual's associative hierarchy;

3. the number of associations one makes;
4. the influence of cognitive and personality styles; and
5. the process of selecting a creative combination.

To make novel associations between elements or ideas, one must have associative elements in mind with which to work. Simply put, one cannot put two things together if one does not have two things. As Mednick stated, "an architect who does not know of the existence of a new material can hardly be expected to use it creatively." Moreover, the more associative elements to which one has access, the more permutations and combinations are possible. Thus, individual differences in experience, memory, knowledge or verbal ability have the potential to affect one's level of creativity given the nature of the task.

The Associative Hierarchy

Associative theory often refers to an individual's associative hierarchy, as shown in Figure 1. The associative hierarchy depicts the ways in which different individuals will produce associations to a problem, such as "how many ways can you think of to use a tire?" An individual with a flat hierarchy will first give common associations like "put it on a car to drive," then is more likely to also make some unlikely or uncommon associations as well, such as "make a tire swing," or "use it as a snow tube for sledding." In contrast, a person with a steep associative hierarchy will also first produce the typical solutions to the problem, but will then show a steeper decline in their ability to keep thinking of ideas, resulting in very few uncommon associations being produced.

Mednick stated that the person with the flatter hierarchy can be said to be the more creative person, while the person with the steeper hierarchy is less creative. Not only did the person with the flat hierarchy produce more solutions in total, but also would produce more original solutions. This pattern of response generation for the more creative person, the person with the flat hierarchy, is explained by postulating that in this creative person's mind, more ideas are connected, but the associations between the ideas are not as strong.

This set up allows for a more interconnected mind, such that a given problem will lead to a wider range of solutions including those which are less common. In other words, word associations for the more creative individual will be less stereotyped or common. For example, a person with a steep hierarchy might respond to 'table' with typical associations like 'cloth' or 'dinner,' but then run out of associations, while a person with a flatter hierarchy might continue on to an answer such as 'ping pong.' For the creative individual, associations may be weaker but they are farther reaching.

The associative hierarchy leads to two important implications. First, if one expects less creativity from an individual with a high concentration of associative strength in only a few responses, then one can predict that the greater the number of occasions on which a person has already solved a given problem using one particular solution, the less likely the individual will be to produce a creative solution in the future. Given the problem of a flat tire, and elements consisting of a spare tire and a wrench, who would generate possible solutions much beyond the tried and true response, "change the tire"? In other words, given the same problem, the same materials, and a solution that worked last time, one will have a steep associative hierarchy. This means that given the same problem and the same materials, an individual who is new to the scene is more likely to be creative than someone who has been presented with the same problem many times before.

Second, the hierarchy posits that most people, no matter the level of creativity, will begin by giving typical answers, or ideas that are not very original. Thus it seems that the novel associations are only produced after one has depleted their reservoir of more obvious ideas. This notion that the more creative ideas will come later in the associative process suggests that when an individual is faced with a problem there is benefit in taking enough time to get past the obvious solutions in order to reach those more remote connections. Such a technique speaks to the power of brainstorming, discussed further below.

The greater the number of associations an individual can produce for a given problem, the more likely their chances are of producing a creative solution. This notion is not

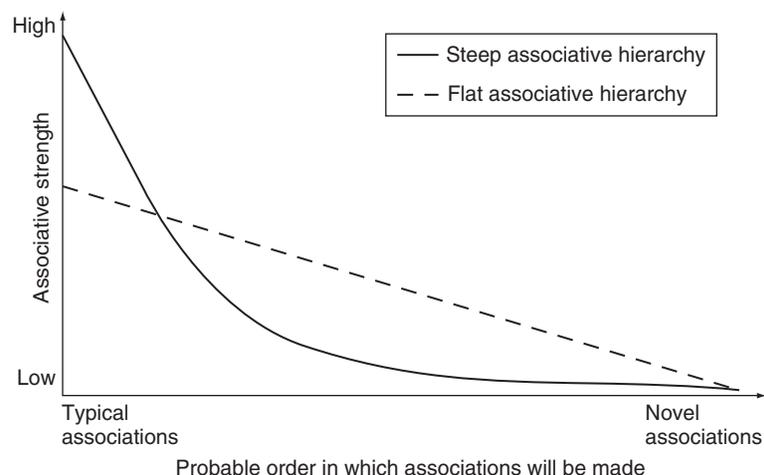

Figure 1 Possible associative hierarchies according to Mednick's associative theory.

completely separate from the associative hierarchy in that an individual with a steep associative hierarchy does not produce as many associations or solutions as someone with a flatter hierarchy, and thus is less likely to produce a creative association. Therefore, a person with a flat associative hierarchy is more likely to produce novel associations not only because of their weaker but broader associations in general, but also due to the sheer quantity of responses they are more likely to generate.

A possible explanation for this phenomenon, based in associative theory, is that the more associations that are made, the more likely it is that a link to a new associative element that will continue facilitating more associations will be found. For example, a person naming animals may begin with unoriginal answers like cat or dog, but once they think of cow, they suddenly have a bridge to a host of other barnyard animals previously unreported. An important note here is that the speed with which someone reaches a creative solution is not taken into account, as mentioned previously, it is usually only after the stereotyped responses have been depleted that more creative solutions are uncovered.

Given that a greater number of associative elements and number of associations produced are both likely to lead to more creative solutions, associative theory must also grapple with how an individual's previously learned methods for approaching a problem and their personality style in terms of persistence or motivation might influence their likelihood of producing creative solutions. Individuals with instruction in brainstorming or other techniques for enhancing creativity are more likely to reach creative solutions.

Selecting a Creative Combination

When making creative associations between elements, a variety of associations can be produced, but what will cause a person to pick one solution to a problem over another? Mednick's answer to this question reaches back to the definition of creativity as a product which is both novel and useful. The 'usefulness' of a solution can be used to distinguish an original solution from a creative one. In other words, the requirements of a problem come to be elements themselves. For example, when asked "how many ways could you use a tire?" it is implicit that the solutions produced must include a tire, and must be a way of using it. Answering "rubber" does not meet these requirements the way that, "put it on a car to drive" does. Furthermore, while "give it as an engagement ring" might be original (in that no other respondent has ever given this answer), it is not a useful solution for what to do with a tire, and thus should not be counted as a truly creative solution to the stated problem.

Mednick asserted that the novel association or solution achieving the closest fit with the set of problem requirements is the solution which gets selected. For example, a diagnosis that is able to explain all of a patient's symptoms will be chosen over a diagnosis that explains only half the patient's symptoms leaving the other half unexplained. The solution explaining all the patient's symptoms is the more useful. Therefore, the creativeness of a given solution can be seen as some function of the number of requirements that the product meets. A solution meeting all the requirements is more creative than a solution only meeting half.

Remote Associates Test

An advantage of the clear predictions made by associative theory about individual differences and creative products is that they are testable. In 1967, Sarnoff Mednick and Martha Mednick operationalized associative theory's definition of creativity with the Remote Associates Test (RAT). Since its inception, it has been used to test a variety of predictions about creative thinking.

The original RAT consisted of about 30 items administered with a 40-min time limit. For each item the subject was presented with three words which seemed to be unrelated (playing, credit, report) and the subject was asked to produce a fourth word that would serve as the associative connection between the disparate words presented (card). The test items were intended to make the subject think creatively, by taking given associative elements and creating a novel combination by providing the mediating link. Mednick emphasized the importance that the links be strictly associative such that a subject must use creative thinking and not logic, concept-formation, or problem-solving to reach the same solution. A subject's score was calculated as simply the total number of correct answers out of 30 items.

Mednick reported the RAT to have high reliability with samples of undergraduate males and females. Original validity studies found that high RAT scorers got good grades from teachers rated as flexible and low grades from teachers rated as dogmatic, and vice versa for those subjects with low RAT scores. Mednick also reported significant positive correlations between high creativity and social attitudes of liberalness. In follow-up papers, RAT scores were also found to correlate with the Creativity Rating Scale (CRS) on which professors were asked to rate the creativity of their graduate students. The RAT was not found to correlate with the Miller Analogy Test (MAT) nor with scores of Grade Point Average (GPA).

However, critiques of the RAT have also been prevalent. The test does not seem to take into account the motivation or other intrinsic factors, including those which Mednick wrote about himself, such as past experience or number of associative elements available which could also affect someone's appeared level of creativity. Later research found that an individual's ability to solve RAT items was significantly related to a variety of cognitive abilities, most notably verbal ability. Daniel Fasko has made similar arguments, citing research showing weaknesses in Mednick's original theory. For example, individual differences show that highly creative people tend to avoid repeating themselves more than less creative people. Fasko asserts that Mednick's associative theory may require some revisions to address the complexity of creativity.

Continual Word Association

In a follow-up paper published in 1964, Mednick and colleagues continued to explore associative theory using a continual word association task. One of the predictions stemming from associative theory was that the greater the number of associations a person makes in response to the associative elements of the problem, the greater the probability of reaching a creative solution. This notion leads to the hypothesis that highly creative people should produce a greater number of associations

when they are presented with a stimulus than less creative individuals.

In this line of research, instead of looking at the associative hierarchy of an individual, the associative hierarchy of individual words were examined. The associative hierarchy of a word is defined by group word association norms. Thus, a word is said to have a steep associative hierarchy if it elicits only one dominant association and then many other associations all of low response strength. In contrast, a word is said to have a flat associative hierarchy if it does not elicit any single dominant response, but instead elicits many responses all of somewhat equal frequency.

Research findings using both continual word association and the RAT seemed to support associative theory and the associative hierarchy notion. Participant's level of creativity, as measured by the RAT, related directly to response frequency. Furthermore, words with flat hierarchies did elicit a larger number of responses than did word with steep hierarchies. In terms of individual differences among words, results found that high frequency words elicited more responses than did low frequency words, and that nouns elicited more responses than did adjectives.

Findings in this area also addressed the speed with which people produced associations. Mednick's hypothesis was that highly creative individuals would respond relatively slowly but steadily, emitting many responses during continual word association. Instead, although the high RAT scorers did produce more responses total, they also did so at a consistently more rapid pace than other groups. Results such as these, showing mixed results with the RAT, suggest that the interpretation of creativity as merely associative behavior is too simple. Creativity is perhaps more complex than initially presented, again suggesting the need for revisions to Mednick's original theory.

Incidental Learning

In his 1967 paper on incidental learning, Patrick Laughlin makes the links between creativity and the use of remote associations clear. It is suggested that the process of forming, retaining and using remote associations is essential in both creativity and incidental learning. Laughlin defines incidental learning as a situation in which apparently irrelevant ideas or relationships must later be associated with each other. Based on associative theory, it is therefore predicted that a more creative individual will display better incidental learning.

Two possible factors are hypothesized to explain the connection between creativity and incidental learning. First, Laughlin suggests that a highly creative person might have greater perceptual sensitivity to the seemingly irrelevant stimulation presented in an incidental learning scenario. Second, it is also possible that the highly creative person is better able to retain the stimuli from the scenario in a more accessible form in order to use the information later for solving the incidental learning task. This notion seems closely linked to Mednick's ideas about the availability of information previously stored. In line with associative theory, Laughlin's incidental learning study results were interpreted as "reflecting wider deployment of attention and less screening out of irrelevant past experiences by high creatives during problem solving."

Other Measures

A wide variety of other association measures exist to further the understanding of associations in creativity. The Kent-Rosanoff Word Association Test (KRWAT) is another word association measure. The measure has shown significant correlations with other creativity ratings for engineering honor students and research scientists. Participants respond to each stimulus word with the first word that comes to mind. This measure was the first to have objective scoring and norms presented in frequency tables; however, the test was criticized for not incorporating individual differences in responses due to factors such as socioeconomic status, age, or education level.

One important development is that tasks such as the RAT are now seen involving some convergent thinking, where information is brought together to form a single solution. Insight tasks would also fit this category. In contrast, associations and creativity are increasingly measured using divergent thinking tests. A divergent thinking test is another measure of creativity which can also be used to explore remote associations and ideational patterns. Divergent thinking is a more open-ended task than the RAT in that subjects are asked to generate as many responses as they can think of to a given stimuli. For example, a subject might be asked to "name all the uses you can think of for a button." Aside from the sheer number of ideas presented by a person (fluency), the individual answers might also be scored in terms of their originality. Current measures used in this area include J. P. Guilford's Alternate Uses Task, Michael Wallach and Nathan Kogan's adaptation of the Alternate Uses Test for children, and the Torrance Tests of Creative Thinking (TTCT).

Psychodynamic Perspectives on Associative Theory

Classic psychoanalytic theory has a different view of associations and creativity. In essence, individual differences in comfort with primary process ideation accounts for the number and originality of associations. Primary process thinking is, according to Robert Holt, drive-laden oral, aggressive, and libidinal content and illogical thinking related to that content. It is a developmentally early, primitive system of thought not subject to logic and heavily affect-laden. Sigmund Freud thought that if individuals repressed 'dangerous' thoughts and wishes, then there would be a general intellectual restriction. In a primary process mode of thinking, ideas are easily interchangeable and attention is widely and flexibly distributed. There should be a broader search for associations for individuals comfortable with primary process ideation. There is strong empirical support for this hypothesis on various divergent thinking and association tasks, especially with male participants.

The psychodynamic perspective is consistent with Mednick's associative theory. It provides one explanation for why some individuals have such a steep associative hierarchy and others have a flat hierarchy. There is a looser connection among ideas for individuals who have easier access to primary process thinking. There is not such a strong bond among ideas and images so that more flexibility of thought and associations can occur.

For true creative production to occur, individuals must go back and forth between primary process thinking and more

logical thinking (secondary process). This ability to access primary process in a controlled fashion is Ernst Kris's concept of "regression in the service of the ego." Because production of a novel and useful product requires original associations and evaluation, both broad associations and critical thinking are necessary. The RAT actually measures both of these processes. As previously mentioned, the RAT is not a pure association task. It has been categorized as closer to an insight task because it requires broad associations but then has one correct answer that must be selected. In psychodynamic terms, one must access primary process thinking and then use critical evaluation to select the right response. Creative production is, at least, a two stage process. In an attempt to test this assumption, James Murray and Sandra Russ used the RAT with college students. They also gave them the Rorschach and scored it with Holt's well-validated primary process measure. The adaptive regression score on the Rorschach reflects both primary process content and the control of that content. This score significantly related to the RAT for the total sample and more strongly in the male participants ($r=0.42$). This relationship was independent of SAT scores. In addition, adaptive regression related to the RAT more strongly than to measures of divergent thinking. We concluded from this study that a two-stage process accounted for the cognitive operations underlying adaptive regression and the RAT. The first stage was a generative stage while the second stage was an evaluative stage. In that sense, the RAT is a more global measure than are divergent thinking tests and is a more accurate reflection of the creative process.

Mood and Associations

Affect and mood are important variables in influencing the range of associations and creativity. Dimensions of affect account for individual differences in range of associations but also can increase frequency and originality of associations when manipulated. Much of the research in this area has used a mood induction research paradigm. Mood is induced by having individuals watch a movie, receive a gift, or think of a memory. In a series of well-designed studies, Alice Isen and her colleagues found that positive affect induction resulted in increased creativity when compared with control groups. She concluded that the positive affect cues positive memories and a large amount of related cognitive and affective content. This process results in defocused attention and a more complex cognitive context, which, in turn, leads to a greater range of associations and interpretations. Interestingly, in one of her studies, she found that induced positive affect resulted in a broader range of first associations to neutral words. They were more unusual and diverse than for individuals in control groups. This is different from what one would predict from Mednick's theory that common associations would occur first for everyone. In another study, Isen did find that positive affect improved performance on the RAT. Results for negative mood induction have been mixed. A few studies suggest that mild forms of negative affect could facilitate some kinds of problem solving tasks. In a recent meta-analysis of 25 years of mood and creativity research, Matthijs Bass and colleagues concluded that positive moods do produce more creativity than neutral

moods if the positive moods are activating (happiness) and associated with approach motivation.

There are other current theories about why the involvement of affect broadens the associations. Gordon Bower's associative network theory conceptualizes emotion as a memory unit. The activation of the memory unit aids in retrieval of events associated with it and primes emotional themes for use in free association. In a model by Issac Getz and Todd Lubart, the emotional resonance model, endocepts that represent emotion are attached to concepts or images in memory. These emotional memories are partially interconnected and can activate one another.

One important implication of the research on mood and creativity is that breadth of associations can be altered by the involvement of emotion, especially positive emotion. The steepness of an individual associative hierarchy gradient is influenced by affect.

Brainstorming

As suggested by the associative theory a large number of factors contribute to an individual's level of creativity, including those mentioned previously such as affect, motivation, past experience, number of associative elements available, and the decision process to choose a creative solution from all the ideas generated. Thus, it can be argued that one's creativity is not a fixed entity, but rather something which can be enhanced or diminished dependent on situation, experience, mood, or one of a host of other factors.

One common technique for enhancing creativity is brainstorming. Brainstorming typically involves generating all the tentative solutions to a problem that one can think of, while postponing evaluation of viability of any of the solutions until after all ideas have been recorded. Sidney Parnes and Arnold Meadow have reported on experimental groups instructed in creative problem solving, in which brainstorming was emphasized. Findings have shown increased productivity on tests of creative ability as compared to controls. With this same group of instructed subjects those who used brainstorming were found to be more creative than a group in which there was a penalty for 'bad ideas.' Further study has found significantly more quality ideas produced in groups instructed to brainstorm than in groups that did not receive instructions to brainstorm. Analyses found a positive correlation between the quantity and the quality of ideas, such that the increase in good ideas created by brainstorming is most likely the result of the overall increase in ideas produced by using the technique.

Brainstorming can be beneficial in both individual and group formats, although results here have been somewhat mixed. Using a group of engineers, group participation in brainstorming was shown to significantly improve the creativity of the group members. Such results fit with associative theory in which the novel ideas produced by one group member might elicit associations to even more novel ideas in another group member. The group format allows for each member's ideas to be the stimulus for others. However, such results will only be found if members can contribute ideas without fear of judgment by others. Groups in which there is

anxiety of evaluation, or groups in which there is a perceived knowledge discrepancy, such as groups containing an expert or leader, can lead to diminished creativity as people withhold ideas to avoid judgment.

Consistent with Mednick's associative theory, several studies by Gary Forbach and Ronald Evans (1981) have found that high RAT scorers use incidental or environmental cues in problem solving more effectively than low RAT scorers. This seems to also be the case in group formats, and has some implications for brainstorming. Instructions to brainstorming groups emphasize the quantity of ideas generated and, at least temporarily, disregard the quality of the ideas. This should lead to the generation of associative cues which should in turn facilitate the further production of ideas by all group members. However, since the high RAT scorers use cues more effectively than low RAT scorers, it is the high RAT scorers who produce more ideas. Put simply, a strong linear relationship between RAT scorer and the quantity of ideas supports the notion that RAT scores can predict brainstorming productivity.

Conclusion

One test of a theory is the impact that it has had on a field. Using that criterion, Mednick's associative theory and the psychodynamic theory of association has been useful. Through theory and research, these conceptualizations focused the field of creativity on the importance of associations in creative thinking. It is now generally accepted that creative production is partially dependent upon having a broad search process and

novel associations. The RAT has proven to be a valid measure of a specific type of creative thinking and has been used in many studies of creativity in adults. Mednick, especially, provided an important foundation, in both his theory and his test, for other research programs and theories to develop. Although criticized as being simplistic in its' view of the creative process, it made a major contribution to the field. Current research and theories continue to focus on the important process of association in generating creative ideas.

Asynchronicity

S Acar, University of Georgia, Athens, GA, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Asynchronicity An appropriate level of discrepancy that may stimulate creative thinking.

Cognitive dissonance Inconsistent cognitions that do not fit together and which motivate creative thinking.

Janusian thinking Cognition that uses two or more contradictory ideas simultaneously.

Person–environment fit Joint influences of individual and setting with similarity between the two expected to nurture creativity.

Tension Inner conflicts experienced as a result of interpersonal or intrapersonal mismatches.

Introduction

A considerable amount of knowledge accumulated in the literature on creativity comes from studies of eminent people whose lives and achievements justify their creativity. This tradition, evident in historiometric and Big-C research, has provided useful information that can be used to help understand creative lives. Asynchronicity is apparent in some of these lives and helps to distinguish creativity from expertise, giftedness, genius, or prodigiousness. It is also critical for understanding the personal, environmental, and domain-related foundations of creativity.

The concept of asynchrony was first discussed in detail by Howard Gardner, who analyzed Freud, Picasso, Stravinsky, Eliot, Graham, and Gandhi in his book *Creating Minds*. However, the effects of asynchronicity had been noted by other researchers. They used synonyms, such as tension, conflict, disequilibrium, or dissonance. This article attempts to show how the construct of asynchronicity has been interpreted in the field and how it relates to those other processes.

Gardner described how 'strategic mismatches or asynchronies' may underlie creativity. He disagreed with the proposition that creativity is the 'wake of the numerous interacting factors' and rather, contended that:

creative efforts are more likely to arise when there is a certain tension or asynchrony among principal factors that underlie human behavior. It is this tension that gives rise to creative works. (p. 101)

Asynchronicity or tension is not simply a situation that exists in creative people's upbringing. In fact, creative individuals often seek it, whereas others tend to do the same for synchrony. Novelties, creations, and new perspectives may be possible for people with unusual or uneven profiles who can think outside the box and see the world in alternative ways.

Three Levels of Asynchronicity

There are different kinds of asynchronicity, including conflicts with family members, homosexuality, early difficulties in school, irregularities in cognitive development, sickness, and loneliness

in childhood. Gardner classified potential sources of conflicts into three levels: personal, impersonal, and multipersonal.

Personal Level

Asynchrony on the personal level can operate in several ways. The first is actually a subpersonal aspect, which is about genetic, neurological, and brain-related differences residing in creative minds. As a matter of fact, attempts to explain such differences such as analysis of Einstein's brain after his death did not yield conclusive results or were abandoned later, as with the argument connecting creativity strongly with right brain function. However, research on people with brain injury and the case of autistic savants who can spontaneously find prime numbers in spite of being unable to perform basic multiplication or reading shows that neurological research promises an explanation of unusual minds. One commonly emphasized unusual characteristic related to brain function is the dominant hemisphere which, for the most part, refers to the left hemisphere taking over sequential, analytic, and verbal process whereas nondominant hemisphere processes are attributed to right-brain action involving simultaneous, visio-spatial or synthetic processes. This design is subject to change, even reversal, when the person is left-handed. Given the fact that most people are right-handed, the highly creative coping skills of left-handed people can be explained by this unusual hemispheric asymmetry. More studies are needed to elaborate upon this aspect of asynchronicity.

Another aspect of asynchrony at the personal level involves cognitive capacities and structures of creative people. As Gardner discussed in detail, creative people may either have unsurpassed levels of particular intelligences, as was the case with Picasso, who had very high spatial and bodily-kinesthetic intelligence with exiguous scholastic intelligence, or may possess an unusual blend of intelligences like Freud, who apparently had superior logical, intrapersonal, and linguistic-verbal intelligence. However, asynchrony sometimes also comes from thinking processes. Some research relating creativity to *primary process thinking*, which enables free association and thinking with metaphors and symbols, rather than *secondary process thinking*, which is logical and goal oriented, is critical to understanding the moment of inspiration and the concept of incubation. Here, asynchrony involves the function of primary

process thinking, which is regarded as an indication of regression serving the ego, while secondary process thinking would represent synchrony among a set of logical thoughts and assumptions.

The role of unusual cognitive patterns in creativity can be extended in different ways. Albert Rothenberg asserted that the creative thinking process involves *Janusian thinking*, which was defined as “the capacity to conceive and utilize two or more opposite or contradictory ideas, concepts, or images simultaneously” (p. 11). He argued that Janusian thinking is basically secondary process thinking that modifies primary process thinking by providing its ‘seeming ubiquity’ and allowing ‘primary-process-like material to appear in consciousness.’ He interviewed Nobel laureates from several fields and concluded that the Janusian process plays a significant role in scientific creativity. He identified four levels of process: (1) motivation to create; (2) deviation or separation; (3) simultaneous opposition or antithesis; (4) construction of theory, discovery, or experiment. Opposing ideas that emerge at the second and third level are often resolved and disappear at the fourth stage. The transition from the third to the fourth stage includes a state of asynchronicity or tension:

Strong motivation provides the drive to consider and conceive the inconceivable; emotional involvement, especially if it involves meaningful conflict, jibes with the cognitive tendency to focus on opposites and antitheses and bring these together simultaneously. The simultaneous opposition and antithesis, with the conceptual conflict retained among composing elements, seems to be isomorphic with emotional conflicts and other psychological processes. (p. 221)

Another critical quality of many creative individuals is their preoccupation with diverse modes of thought simultaneously. Divergent thinking accompanied by evaluative thinking or imaginative cognition paired with realistic cognition would mostly result in creativity, although they may not achieve that independently. Arthur Cropley argued that creativity is the consequence of the joint influence of divergent and convergent thinking, which are seen as opposing thinking modes. He supported this hypothesis with the case of Vincent van Gogh, whose artworks became well-known after he learned basic techniques of painting. His artistic potential, represented by divergent thinking, would not have been fruitful had he not acquired convergent thinking. Mark A. Runco added that even incompatibility between such diverse modes of thought might be useful when tension is triggered.

Some empirical studies can also be approached as documenting asynchronicity emerging at the cognitive level. Roni Reiter-Palmon and her colleagues examined the influence of cue consistency on problem construction. They found that the quality and originality of the solutions were higher in the presence of inconsistent cues. It is quite possible to argue that tension springing from inconsistent cues might elicit creativity. According to Keith James and his colleagues, tension frequently functions as a signal that indicates a need to fix, modify or resolve on the perceiver’s part.

The third aspect of asynchrony on the personal level is noncognitive, which is more about personality and emotions. The creativity literature lists numerous personality characteristics of creative individuals that can be related to marginality

such as childlike nature, daydreaming, playfulness, contrarianism, and nonconformity. Each of those characteristics can be seen as a source of asynchronicity. Einstein is a remarkable case for the role of personality in creativity. Gardner argued that Einstein preserved his childlike nature and naivety even as an adult, and this enabled him to approach problems in a different manner from others. In this way, he was able to ask the critical questions the answers to which he could find later. For example, the question “Why is the sky blue?” would be a childhood curiosity for many who later quit thinking about this question without searching for any answers. What makes Einstein and few others different is their unending interest in such basic yet significant questions that would lead to many scientific elaborations.

W. Ed McMullen argued that many creative people are ‘paradoxical personages’ by which he referred to the coexistence of eight polarities in their personalities. First, most creative people tend to delay closure and are open to new ideas while at the same time they feel a strong urge to achieve closure and eventually form a gestalt. Second, they are inclined to swing between the modes of lateral thinking and logical thinking. Third, they can also merge the unconscious into consciousness which allows them to keep up ‘mindless perception.’ Fourth, creative people are often fault finders and destructives, but they also reconstruct and make new syntheses. Fifth, they mostly have passion, but they also need to stay calm and reasonable. Sixth, they are both ego-centered and empathetic since they desire success, power, fame, and honor, yet are also altruistic, concerned about others and their well-being. Seventh, they are usually confident about their abilities and proud of their successes while they are humble and aware of their weakness and ignorance for the most part. Last, their insight emerges when they are in a state of relaxed attention, which is the moment of shift between work and relaxation. Likewise, Mihaly Csikszentmihalyi discussed the complex personality of creative people as an integration of contradictory extremes. He argued that creative people are usually both energetic and quiet, smart and naïve, disciplined and playful, imaginative and realistic, extroverted and introverted, humble and proud, masculine and feminine, rebellious and traditional, passionate and objective, and suffering and joyful.

As for emotions, relationships with the opposite sex are mostly exploitive and temporary. In such cases, broken relationships were sometimes followed by suicides. As Arnold Ludwig showed in his search for the ‘Price of Greatness,’ higher rates of suicide among members of the sample with exceptional creative achievement was one of the costs that some of them encountered. Also, several studies indicating a relationship between mood disorders and creativity can be looked at within the realm of personal noncognitive asynchronicity. The frequent association of creativity with mental illnesses, specifically mood disorders, should be recalled here. Nancy Andreasen found that 80% of creative writers experienced a mood disorder like depression, mania, or hypomania at least once in their lives. In another study by Hagop Akiskal on award winning European artists and writers, two-thirds of the participants reported cyclothymic or hypomanic tendencies, and half of them experienced a major depression. Mood swings of creative people provided them with unique perspectives which were scarcely achieved by those with regular moods.

Impersonal Level

The second level of asynchrony involves the domain of knowledge, the impersonal level, where creative individuals need to interact. Knowing about the domain is a necessity for making a contribution to or challenging it. There was no cubism, psychoanalysis, or physics of special relativity before Picasso, Freud, and Einstein learned about, influenced, mastered, and evolved the domains, and eventually created their own domains. If they had been in complete agreement with their domains, they would not have revolutionized those domains and shaken the earth. Therefore, discontent or dissatisfaction with the domain is often fruitful and can initiate epistemological changes in that field. A good example of this is Freud, who began with philosophy and switched to scientific medicine. Going through neurology, neuroanatomy, and psychiatry, he came up with a new domain, psychoanalysis, which influenced many other domains from visual arts to political science.

Knowing a domain is a crucial aspect of creativity because the learning process brings recognition of the gaps and inconsistencies regarding the content. Scientific creativity has a lot to do with the domain. In the sciences, many contributions arise from those gaps and inconsistencies in the domain. In physics, for example, Newton's physics represented the core of the domain for a long time, and Einstein acknowledged that:

The whole development of our ideas concerning natural phenomena [...] may be conceived as an organic development of Newton's thought

in the article in which he discussed the limitations and weaknesses of Newtonian physics.

Multipersonal Level

The third level of asynchronicity is the perspective of the field, which is the multipersonal level. Creativity does not come out of a vacuum. There may have been many creative ideas that remained unrecognized because the people who evaluated the work did not find them impressive and valuable. Such lack of fit between the creative person and the field might result in a fruitful asynchrony in cases where the creative people could resist the forces of the field and launched their own influence in spite of the price such as being alone like Freud. Mihaly Csikszentmihalyi mentioned E. O. Wilson and presented his works as an example of attempts to construct a new domain called Sociobiology, connecting social sciences with evolutionary biology. Just like the examples above, he had severe disagreements with people within the field. Another example of asynchrony at the multipersonal level is Hilde Domin, who is a famous poet and writer. She had to wait for 6 years to publish her poems because of the politics of the field. Her naivety and lack of knowledge about a 'literary mafia' helped her to sustain and have an independent literary career.

Dichotomous Classification

The asynchronicities exemplified above are simply based on Csikszentmihalyi's systems approach involving the interactive or dialectical relationship of the three elements: person, domain, and field. Mark A. Runco preferred *tension* to represent

the construct, and classified asynchronicities into two groups: intrapersonal and interpersonal. With this categorization Runco related the personal level to intrapersonal tension that implies a misfit between the situation and its perception by the individual, or to inconsistent thoughts that associate the field and domain with interpersonal tension.

Intrapersonal tensions are crucial for creativity. Csikszentmihalyi used the term *cathartic originality* to describe the underlying processes of artworks. He argued that the discomforts that are rooted in repressed tensions of childhood may stimulate creative works after the individual becomes mature and better able to handle them. Unsurprisingly, psychoanalytic views on creativity have supported this argument. William G. Neiderland reported that psychoanalysts encounter common factors such as tragic early childhood experiences, traumatization and conflicts, loneliness, loss, and discontent with body image among creative people in their clinical experiences. Many creative people's response to such unfortunate experiences is a heightened emotional reactivity that evokes their awareness of already existing oversensitivity to internal and external stimuli. The feelings of being incomplete, ugly, and deficient among creatively active individuals are often replaced by sensations of completeness, adequacy, and strength through artworks. Martin S. Lindauer explained the stylistic changes of artists in the same way. Personal conflicts like physical or emotional handicaps are sometimes compensated for through artworks. The presence of grief, ordeal, pain, and irregularities in biographies of some creative people confirms this notion.

In the intrapersonal case, further elaborations can be made. For instance, Leon Festinger called tension arising from two or more inconsistent cognitions *cognitive dissonance*. According to him, it is human nature to sustain an internal consistency among opinions and attitudes. This consistency is a state of consonance and equilibrium in which individuals are free of tension. With the emergence of new situations or the acquisition of new knowledge, existing cognitions are challenged, and individuals are motivated to reduce the dissonance and achieve consonance again. Therefore, the presence of dissonance is mostly an antecedent condition that stimulates human cognition to a new synthesis. This is how cognitive dissonance may result in creative thinking. Colin Martindale hypothesized that creativity is related to resistance to cognitive dissonance in the sense that creative people, unlike most others, may not be motivated to achieve consonance. The more people tolerate novelty and deal well with incongruity and respond to it in a flexible way, the more they experience dissonance, taking advantage of it, and eventually, the more creative they become.

Is this the case in real life? Edward Boring, who wrote '*Cognitive Dissonance: Its Use in Science*,' argued that:

Any reader of Kepler's biography will wonder how the three great planetary laws could have emerged from so inconsonant a mind, in which mysticism was mixed up with a passion for accurate observation, which perceived as one of its great intellectual achievements the spacing of the six planets in the solar system as related to the shape of the five regular geometrical solids, a mind which took astrology seriously, and which experienced ecstasy over both its true and false successes. (p. 683)

Cognitive dissonance theory makes it possible for creativity researchers to see the link between intrinsic motivation and

creativity, given the fact that Festinger regarded cognitive dissonance theory as fundamentally motivational. Since dissonance is discomforting, it often functions as a source of arousal. The dissonance provides most people with a directional goal in terms of which they can either search for memories to support the desired conclusions or search out new knowledge to create a new explanation. The latter is actually how cognitive dissonance leads to the motivated reasoning resulting in creativity.

According to Jean Piaget, intrinsic motivation is preceded by certain cognitive operations. This occurs when individuals encounter new knowledge that they cannot make sense of. In this case, new ideas are not compatible with current conceptions, and disequilibrium emerges and continues until the individual assimilates or accommodates to reach equilibrium again. At that point, it is critical to point out that creativity is achieved as long as individuals can adapt to new information and expose themselves to perennial conflicts, even as they grow older. Morris I. Stein also acknowledged the role of disequilibrium, claiming that it takes place at the beginning of the creative process.

Another kind of asynchrony is related to cortical arousal. Colin Martindale argued that something is wrong with the arousal system of creative people. He observed that their arousal level does not linearly increase with the arousal potential of the stimuli. At some point, there is a 'dip' in their arousal, which seems to correspond to the moment of inspiration, unlike uncreative people, whose cortical arousal increases with the arousal potential of the stimulus. He showed that the EEG activity of creative people was lower during the inspiration phase than uncreative people, whereas there was no difference in the elaboration phase. He linked lower level of arousal with the unfocused attention that enables elaboration of several mental elements simultaneously.

Asynchronicities at the interpersonal level may occur in the family environment, too. Robert S. Albert and Runco argued that incongruent parent-child relations can create tension, which enables the child to develop autonomy. From a factual standpoint, loose relationships of eminent physical and biological scientists with their parents as well as findings regarding the high rates of parental loss in the exceptionally gifted population seem to support this hypothesis. Sibling rivalry, family size, birth order, and parental expectations are important factors to be considered as potential sources of asynchronicity at the interpersonal level.

Considering the larger spectrum, cultural marginality could also be mentioned under the umbrella of the interpersonal level. According to Thorstein Veblen, the intellectual success of the Jews in Europe is related to their cultural marginality. In Freud's case, he had to leave Austria because of Nazi oppression. Before his life in France, Picasso lived in Spain and kept his ties with his native country. According to Csikszentmihalyi, a distinguishing feature of the centers of creativity throughout history was that they were at the crossroads of cultures and cosmopolitan life in those cities.

Asynchronicity Versus Person-Environment Fit

A frequently mentioned factor involved in creativity is the rule of 'being in the right place at the right time,' which refers to a

good match of the person with familial, social, economic, political, or cultural surroundings. According to this view, the concurrent presence of these advantages paves the way for creativity. Creativity is defined as the outcome of the individual's behavior in a context. Therefore, the joint contribution of person and environment should be taken into consideration. To exemplify this, a nonconformist individual within an environment that encourages or tolerates nonconformity would be a good match for creativity. However, the asynchronicity approach seems to disagree with the idea of person-environment fit.

According to asynchronicity, the coming together of several positive factors or coincidences may explain the emergence of prodigiousness or eminence, but not creativity. For this reason, the rule of 'being in the right place at the right time' works in the opposite manner for creative people: for creativity to emerge at least to some degree, the right time and place implies a context that brings lack of fit or disharmony. According to Runco and Joni R. Gaynor, the matching should be optimized so that an appropriate level of discrepancy for creativity is maintained. For this reason, Simonton described the best mentors as those who fall between the 'too similar' and 'too dissimilar' ends. Daniel Rubenson and Runco also argued that an optimal mix of individuals is necessary for creative productivity. This also means that too much as well as too little asynchronicity is mostly unproductive.

Unproductive Asynchronicity

In their discussion of the concept of asynchronicity, Gardner and Contance Wolf asked the following question: "When does asynchronicity become counterproductive?" This question was legitimate, given the observations (i.e., Aristotle: "All extraordinary men distinguished in philosophy, politics, poetry and arts are evidently melancholic") and research findings such as those associating creativity with madness. Runco admitted the interpretive nature of tension that makes it hard to generalize, and responded to Gardner with "more is not necessarily better." According to him, even the optima may not be optimal at certain times. While some amount of asynchrony motivates, it may be inhibiting when it becomes excessive. Ideally, it is best when

the tension is distributed such that the individual is not overwhelmed by one experience, nor from accumulation of disturbance and depletion of resources. (p. 188)

Briefly, the optimum level of asynchrony is the situation where individuals are challenged but can adapt and grow. According to Michael Rutter, the optima depend not only on the amount of tension but also on the way individuals react to it. The cognitive capacity of individuals determines how much tension they can successfully cope with.

On the other hand, such generalizations may also fail in several cases. Keith James found that originality is improved when people perceive conflicts in the domains on which they focus. Howard E. Gruber went further and argued that the association of tension with fields ranging from sciences to arts differs. He suggested that sciences are linked with interpersonal tension while arts are related to intrapersonal tension.

As a result, there may be domain-dependency in the optimal level of tension. Csikszentmihalyi described the optimum level of asynchronicity between the person and the fields as follows:

The creative individual must reject the wisdom of the field, yet she must also incorporate its standards into a strict self-criticism. And for this one must learn to achieve the dialectical tension between involvement and detachment that is so characteristic of every creative person.

The inverted-U-shape relationship between creativity and asynchronicity has been attributed to several reasons. According to Martindale, optimal performance occurs at a moderate level of cortical arousal. James A. Easterbrook proposed that this relationship is mediated by task complexity: higher levels of arousal are efficient for simple tasks but not for complex tasks. Task performance decreases at low or high arousal levels compared to the optimal level because of the presence of irrelevant cues or lack of several cues, respectively. Optimal performance should be expected when individuals have several cues that can be used for a novel and original idea.

In a study on the comparison of high versus low creative people with respect to anxiety and defense mechanisms employed, Ingegerd Carlsson found that the high-creative group had more anxiety than the low-creative group. Particularly, she reported that mild and moderate signs of anxiety are found 'almost exclusively' among the high-creative group as measured by meta-contrast technique. If we consider anxiety as a form of asynchronicity at the personal noncognitive level, these findings confirm an inverted-U-shape relationship between asynchronicity and creativity. An example of unproductive asynchronicity in organizations is intensified interpersonal conflicts. Although some level of conflict helps new ideas and syntheses to emerge, too much conflict undermines a positive working environment, resulting in rumors, gossip, and destructive competition.

Asynchronicity in Practice

Education

If asynchronicity is essential for creativity, can we create asynchrony to stimulate and enhance creativity? According to Piaget, children do not show interest in any stimulus if it is far above their cognitive level or when it is a routine task. The ideal situation is the presentation of stimuli that are somewhat challenging but graspable for a child. This level of discrepancy was disputed by Lev S. Vygotsky, who introduced the concept of the *zone of proximal development*, defined as:

the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance, or in collaboration with more capable peers.

The creative potential of children can be maximized through challenges that fall within the zone of proximal development. According to Runco and Radio, one critical factor for parents and teachers is their recognition of creativity in children because providing environments that support creativity is only possible if they believe that the children possess it at

some level. Once they have a realistic perspective about the creativity of their children, they can regulate their expectations (known as *scaffolding*).

Apparently, the view of asynchronicity has solid bases in education. Contrary to frequently suggested approaches such as unconditional positive regard, which refers to acceptance of ideas without any criticism, asynchronicity suggests confronting the individual with the defects and drawbacks of creative products and encourages showing ways to improve creativity at the creator's pace. However, this may become unproductive, depending on the children's perceptions. Instructional activities can be designed in such a way that students experience tension. Teachers can point out, for example, the gaps and incomplete parts of the ideas and theories instead of merely providing the facts. According to E. Paul Torrance, tension is aroused when we sense incompleteness or disharmony. This tension lasts until we come up with explanations or solutions resulting from long-lasting processes of trial-and-error, manipulation, guessing and testing. Having students notice and recognize disharmony and incompleteness can be intriguing and curiosity-provoking.

Organizations

Asynchronicities are useful for organizational creativity, too. Indeed, Michael A. West argued that innovation and conflict are concomitant:

If a new way of doing things is introduced within an organization and no conflict is generated (that is, there are no disagreements about the content or process of the innovation), or if there is no resistance by organization members to the innovation, then this innovation is not really new nor does it offer a significant contribution to the organization. Innovation threatens the status quo and thereby produces conflict. (p. 101)

Various benefits of conflict and asynchronies have been found in studies of organizations and the workplace. Lorraine Dagitino suggested that brainstorming techniques should be designed to yield ideational conflicts because creative ideas arise from conflict and confusion. Victor A. Thompson complained about the conditions within a bureaucracy led by a monocratic social structure. Driven by the purposes of productivity and control, these conditions do not contribute to creativity and should be changed. He suggested a looser, decentralized, and evolving structure, which allows freer communications, rotation of assignments, modification of the incentive system, and changes in management practices. Empirical studies support the role of conflict in organizational creativity. Keith James and his colleagues found that conflict can enhance or hinder creativity depending on the situation and individual. Perceived conflict improved creativity on tasks that match an individual's orientation and reduced it for tasks outside of that orientation.

Objective Assessment of Asynchronicity

As Gardner and Wolf acknowledged, finding asynchronicities is not difficult. This can make the concept more elusive and subjective for scientific study. As a matter of fact,

even with the benefits noted above, there is no objective way of assessing both asynchronicities and synchronicities. The lack of empirical research on asynchronicity is a corollary of the absence of objective criteria. However, some special methods of measuring creativity are based on ideas similar to asynchronicity. One such example is the Chiara S. Haller and Delphine S. Courvoisier approach to personality tests as an indicator of asynchronicity given the premise that the response pattern of creative people is complex. Complexity of their responses stems from the presence of contradictory traits in their personalities. Haller and Courvoisier hypothesized that creative individuals will be inconsistent in their responses to test items, choosing contradictory poles. Therefore, we would see more variability in the responses of creative people than in those of noncreative people. They tested this hypothesis by comparing students from art and psychology majors. They found that complexity in conscientiousness was greater among visual art students than music and psychology students, and visual art students showed greater overall complexity than psychology students.

Another idea that is consistent with asynchronicity is to measure creativity based on the hypothesis that creative people prefer asymmetry over symmetry. The Barron Welsh Art Scale is an example of this kind. The scoring was based on whether participants like or dislike stimuli which are either symmetrical or asymmetrical. The underlying idea is that creative artists prefer asymmetric, irregular, or even chaotic figures. John C. Rosen found that this test discriminated artists from nonartists, while scores were not significantly different between art students and established artists. Further attempts to clarify the definitional scope and objective assessment of asynchronicities would stimulate studies of the role of asynchrony in creativity.

Conclusion

Asynchronicities in the lives of creative people are many and can be classified into three groups – personal, impersonal, and multipersonal, or two groups – interpersonal and intrapersonal. Asynchronicity provides a unique perspective for understanding creativity, and the wide range of asynchronicities complies with the recent conceptualizations of creativity as a ‘syndrome.’ A certain level of asynchronicity seems to be helpful for creativity, but too much may be counterproductive. A critical issue regarding asynchronicity research is the difficulty in assessing it as we lack objective measures. Asynchronicity also challenges the view of person–environment fit, which asserts that synchrony between the person and environment is favorable for creativity. Further studies are needed to resolve this controversy.

Attention

B M Dupuy and R S Friedman, University at Albany, State University of New York, Albany, NY, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Attentional priming A broadening or narrowing of the scope of conceptual attention elicited by a corresponding change in the scope of perceptual attention.

Attentional scope The amount of perceptual or conceptual information selected for cognitive processing.

Conceptual attention The selection of stored information from long-term memory for potential access to consciousness.

Latent inhibition The ability to filter from attention stimuli that are perceived as irrelevant to a current goal.

Nonaffective cues Stimuli that do not involve conscious experiences of pleasure or pain, but that are associated with, and at least implicitly signal benign versus threatening situations.

Theoretical Considerations

Psychological research exploring the role of attentional selection in creativity has substantially contributed to elucidating, and thereby demystifying, the processes by which innovative alternatives are generated. Contemporary empirical inquiry into the link between attention and creativity is grounded in the work of associative learning theorists, who more than a half-century ago proposed that the capacity to innovate is influenced by the way that the strengths of potential responses to stimuli are distributed. Specifically, among individuals with more steeply graded distributions, closely associated responses to a particular stimulus possess a disproportionate amount of strength, rendering these responses extremely likely to be emitted to the exclusion of other, more remotely associated responses. For example, in a verbal free association task in which individuals are asked to generate words that come to mind in response to a given cue, those with steeper associative response gradients may only generate closely associated responses such as 'chair' or 'cloth' when presented with the stimulus word 'table.' In contrast, among individuals with flatter associative response gradients, the probabilities of emitting closely versus remotely associated responses are more equally distributed. Therefore, such individuals may be more likely to produce responses that are distantly related to the stimulus – for instance, 'leg' or 'fable' in response to the word 'table.'

Critically, since individuals with flatter, more distributed, response gradients are relatively inclined to produce remotely associated responses to a particular stimulus, they are posited to show greater creativity, as the availability of relatively unconventional responses is essential for the production of novel yet practical solutions. In an early test of this proposition, individuals were administered the Remote Associates Test (RAT). On this task, individuals are required to find a word that associatively links three distantly related words (e.g., ATOMIC FOREIGN MOWER — — —; Answer = POWER). Performance presumably benefits from possession of relatively flat associative gradients, as correct answers constitute non-dominant responses with respect to all three stimulus words – for instance, 'power' is only weakly linked to 'foreign.' In support of the notion that flatter response gradients are associated with

higher creativity, it was found that RAT performance was positively correlated with several indices of creative ability, including the originality of scholarly research.

Recently, the classic ideas of the association theorists regarding the link between individual differences in response gradients and creativity have been fruitfully reconceptualized as involving variations in attentional processes. According to a number of theorists, attention may be seen as a process of selection that occurs on both the perceptual and conceptual levels. On the perceptual level, individuals may focus attention broadly, to select a wider array of external stimuli for processing, or narrowly, to restrict selection to a limited subset of these stimuli. For instance, when viewing a desktop computer, attention may be directed broadly, to encompass the CPU, monitor, and keyboard, or narrowly, to encompass only one or two of these external stimuli, the reflections of which are impinging on the visual system. However, individuals not only need to select percepts for processing on the external level, but also to select which concepts in memory they will activate, that is, bring to mind, to play a role in conscious thought. Broader conceptual attention may be viewed as a tendency to activate a wider array of interconnected concepts stored in long-term memory, for instance, the concepts of 'CPU,' 'monitor,' and 'keyboard,' whereas narrower conceptual attention may be seen as a tendency to activate only a smaller subset of these concepts.

In light of the assumption that potential responses are stored in, and activated from, long-term memory in the same manner as semantic concepts, it has recently been proposed that the flatter response gradients described by the associative theorists may be viewed as a special case of broadened conceptual attention, and steeper gradients as a special case of narrowed conceptual attention. This insight has helped inspire a growing body of research aimed at addressing the factors that moderate the scope of conceptual attention, expanding or constricting access to information stored in long-term memory, and thereby facilitating or impeding creative thought. Researchers have investigated the influence on creativity of both chronic individual differences as well as transient situational variables posited to moderate conceptual attentional breadth. While this research is still in its nascent stages, a number of major findings have emerged in recent years.

Conceptual Attention and Creativity: Research Findings

Individual Differences

To recapitulate, the scope of conceptual attention may be understood as the quantity of information that is rendered accessible to consciousness at a given point in time. Broader conceptual scope signifies that a greater number of concepts in long-term memory, including those remotely associated with the stimuli that currently occupy focal awareness, are poised to enter into conscious thought. Given this view, it may be argued that an important phenomenon associated with conceptual attention is the extent to which information that is irrelevant to ongoing goals retains accessibility to consciousness. For instance, if an individual is locked out of his or her car, concepts such as 'keys' and 'lock' may be highly accessible to awareness because they are relevant to the goal of regaining entry. However, perceptual stimuli, such as the sound of passing cars, and conceptual information, such as the makes and models of these cars, should be screened from awareness inasmuch as they are both irrelevant to goal pursuit and only stand to foster distraction.

Latent inhibition (LI) is an attentional process by which both perceptual stimuli and conceptual information deemed irrelevant to current pursuits are automatically (i.e., latently) filtered from conscious awareness. At first blush, it would seem that this is an entirely adaptive process, the absence of which would promote confusion and disruption of ongoing behavior. Indeed, consistent with this inference, there is compelling evidence that individuals who exhibit lower LI are more prone to disordered thought and ultimately more likely to be diagnosed with schizophrenia. However, consistent with the foregoing proposition that broad conceptual attention facilitates creative cognition, it may be proposed that reduced LI should also increase the amount of information accessible to conscious awareness for use in devising innovative alternatives. To clarify, individuals who fail to filter out presumably irrelevant information will retain this information such that it may be considered along with information presumed relevant. When concepts activated during a prior task are considered along with those deemed pertinent to a current task, this may serendipitously foster the discovery of creative combinations of ideas.

Logically speaking, if attenuated LI fosters innovation, it should be correlated with personality traits associated with increased creativity. According to personality researchers, two such traits are openness to experience and extraversion. Openness is characterized by intellectual curiosity and the proclivity to seek out new and unusual ideas. Extraversion is also characterized by a penchant for exploratory behavior, but more broadly reflects sensitivity to, and a tendency to seek out, rewarding stimuli in the environment, including, but not limited to, social stimuli.

In recent work investigating the link between these personality traits and LI, research participants were presented with a repeating sequence of nonsense syllables interspersed with bursts of white noise. Their focal task was to count the number of times a particular syllable appeared. Here, the noise bursts were irrelevant to task completion, rendering it adaptive to exclude them from focal attention. In a subsequent task, the same interspersed auditory stimuli reappeared; however, the

nature of the task was altered: Colored disks now additionally appeared on screen immediately preceding the offset of each noise burst and participants were responsible for identifying the temporal association between these bursts and the newly presented visual stimuli. This involved attending to stimuli, here, noise bursts, that were previously irrelevant. Therefore, to the extent that individuals had already allocated attention to these irrelevant stimuli on the first task, they should more readily attend to them on the second task. As such, reduced LI was operationally defined as faster identification of the connection between noise burst and colored disk onset in the secondary task, reflecting an initial broadening of attention to encompass both relevant and irrelevant information. Interestingly, those who showed reduced LI on this measure also scored higher in assessments of both openness to experience and extraversion, suggesting a link between attenuated LI and traits known to be associated with creative endeavor and achievement.

Of course, findings such as these present a rather puzzling quandary: If reduced LI is associated with both psychosis and creative achievement, what distinguishes reduced-LI individuals who produce great creative works from those who degenerate into madness? Cutting-edge research has suggested that at least one critical moderating factor may be intelligence. Eminent creative achievement is significantly more likely among individuals with both reduced LI and higher IQ scores. Although the exact reason for this interaction remains poorly understood, it has been speculated that high IQ may allow individuals to adaptively control how thoughts that unintentionally gain access to awareness are utilized. Given this enhanced ability to regulate how the contents of consciousness are employed, high IQ individuals may benefit from access to irrelevant details as these may contribute to a larger base of material from which to generate innovative alternatives. Individuals with higher IQ may also be better able to cope with the maladaptive consequences of reduced LI, those associated with enhanced proneness to psychosis, thereby preserving their ability to benefit from its creativity enhancing effects.

Situational Factors

Recent research has also made great headway in identifying variables that may transiently influence the scope of conceptual attention, and thereby creativity, within the same individual under different circumstances. The bulk of this work pertains to the attentional impact of signals regarding whether the current situation is relatively benign or threatening.

Affect

Perhaps the primary signal regarding the extent to which an individual is currently safe or in danger lies in his or her affective responses, the emotions or moods that he or she experiences in a given situation. Positive affective states, such as happiness, signal to individuals that their current situation is benign or safe, whereas negative affective states, such as anxiety, signal that the situation is dangerous. Several theorists have recently proposed that these signals also tune the scope of conceptual attention, with negative affective states constricting, and positive states expanding the range of stimuli that are rendered accessible to consciousness. Undergirding this proposition, it has been

argued that the constricted focus of attention associated with negative affective states should be adaptive in dangerous or threatening situations because it reinforces an exclusive focus on the problem at hand and information pertinent to solving this problem. Attention to ideas or plans of action that are irrelevant to a current threat generally stand to foster distraction and thereby heighten potential risk. Correspondingly, the broader scope of attention associated with positive affective states has been posited to make individuals more likely to engage in novel thought and action patterns. This is posited to help them build their repertoire of knowledge and skills, and to acquire additional resources, such as new social connections, all of which ultimately aid in survival. Restated, exploration of new ideas when the situation is relatively benign, a process facilitated by an expanded scope of conceptual attention, may help individuals develop skills useful for surviving future crises.

The notion that positive, relative to negative, affective states broaden the scope of conceptual attention has received empirical support in a number of studies. One common paradigm used to assess this hypothesis involves either experimentally inducing or measuring differences in current mood, then having participants complete a categorization task in which they are to rate the goodness-of-fit of a set of exemplars to a number of familiar categories (such as furniture, vegetables, or vehicles). The exemplars given vary systematically in their prototypicality. For instance, 'bus' and 'camel' may be offered as relatively prototypical and nonprototypical members of the category 'vehicles,' respectively. More inclusive categorization, revealed by rating nonprototypical exemplars as better fit to their overarching categories, can be seen as at least partly resulting from broadened conceptual attention, as this entails increased cognitive access to features shared between more and less typical exemplars. To illustrate, broader conceptual attention may help individuals recognize that both a bus and a camel make groaning noises and emit noxious odors, thereby leading them to judge a camel as more vehicle-like in nature and thereby as a better fit to the category.

Notably, using this categorization paradigm, it has been found that individuals in positive moods are more likely to accept less prototypical exemplars as category members (including 'camel' as a vehicle and 'cane' as a type of clothing). In complementary fashion, it has been found that individuals who are currently or chronically anxious are less likely to accept nonprototypical exemplars as category members. Consistent with these results, multiple studies have also demonstrated that individuals in positive, relative to negative or neutral moods show improved RAT performance (see above) and a tendency to produce unusual free associations to a given word, suggesting that they are more likely to bring to mind material from memory that is comparatively inaccessible to consciousness.

Given the hypothesized link between mood and conceptual attention, and between broadened attention and enhanced creativity, it may be predicted that positive, relative to negative, moods enhance creative performance. Accordingly, a host of evidence has been marshaled in support of this proposition. For instance, in one set of studies, individuals were induced into different moods and asked to solve the Duncker candle task. In this classic task, participants are presented upon a

table with a candle, a box containing tacks, and a matchbook. They are asked to attach the candle to the wall such that it does not drip wax on the table. Most participants fruitlessly attempt to pin the candle directly to the wall using the tacks or to glue it to the wall using melted wax. However, the only viable solution involves pouring the tacks out of the box and using the container as a pedestal for the candle. Responding in this manner has been characterized as requiring an ability to overcome functional fixedness, that is, the capacity to use an object with a previously well-established function in a new way. This ability may be viewed as a special case of breaking mental set, a fundamental component of creativity. Moreover, it may be seen as benefiting from expanded conceptual attention, inasmuch as this should increase accessibility to associations that are relatively remote from conscious awareness, for instance, the nonobvious idea that the box is not only a container, but an object in its own right that can be attached to the wall. In line with the hypothesis that positive moods expand conceptual attention and thereby bolster creative thought, both children and young adults induced into mildly positive moods have been found to be more likely to solve the candle task than those in neutral or mildly negative moods.

However, despite the presence of much supportive evidence, other recent findings have suggested that the foregoing conclusions regarding the influence of affect on attention and thereby creativity may be oversimplified. For instance, according to mood-as-input theory, the effects of mood on creativity result less from the moderation of the scope of conceptual attention and more from differences in sheer effort. Provocatively, the theory also proposes that the effects of mood on creativity may be reversed under certain circumstances. Essentially, mood-as-input theory proposes that the information provided by positive and negative moods can either facilitate or diminish the amount of effort that individuals put into generating creative alternatives. The effects of mood on creative effort depend on which stop rule is used during performance of the task. If individuals are led or inclined to adopt an enjoyment-based rule – "stop when you no longer enjoy the task" – those in positive moods assume they do enjoy the task and continue to put in effort, whereas those in negative moods assume they do not enjoy the task and withdraw effort. This ultimately leads those in positive, relative to negative moods to show enhanced creative output. In contrast, if individuals adopt a performance-based rule – "stop when you've reached an acceptable level of performance" – those in positive moods assume that they feel good because they have done enough and thereby reduce their efforts, whereas those in negative moods assume they feel bad because they have yet to accomplish enough and thereby increase their efforts. This leads those in negative moods to surpass those in positive moods in terms of creative output. These predictions have been confirmed in several studies.

While this model cannot necessarily account for all effects of mood on creative thought, for instance, effects on RAT performance or flexibility in categorization, it does at the very least suggest that the effects of moods and emotions on conceptual attention and creativity may be supplemented, if not overridden by, more context-dependent and deliberate decisions regarding effort allocation. It has also been shown that

positive and negative moods can sometimes facilitate creativity through qualitatively distinct mechanisms. Specifically, positive affect may indeed expand the scope of attention, enabling access to material used to devise innovative alternatives, whereas negative affect may constrict attention, but compensate for this by mobilizing the effort to generate more potential solutions from the comparatively limited cognitive material that remains available. In sum, while it is clear that both conceptual attentional scope and effort allocation are significant moderators of the influence of mood on creativity, a comprehensive understanding of their unique and interactive effects will require additional research.

Nonaffective cues

As discussed in the preceding section, although its interplay with other variables related to creative output has not been fully elucidated, the tuning of the breadth of conceptual attention by positive and negative affective states has been proposed to be adaptive for survival. To reiterate, the narrowing of conceptual attention associated with negative affective states helps individuals focus on information most relevant to escaping a current threat, and when that threat has passed, the broadening of conceptual scope associated with positive affective states helps them learn new skills that might aid in escaping or avoiding future threats. However, while affective experiences, such as emotions and moods clearly constitute essential signals conveying to individuals that they are in relatively benign versus threatening situations, they are not believed to be the only signals that serve this purpose. Rather, it has been proposed that individuals are capable of intentionally or unintentionally using countless cues from their bodies or from the external environment to determine whether they are relatively safe or threatened. Therefore, while positive and negative affective experiences may wield a particularly powerful influence on the breadth of conceptual attention, there may be a range of other, perhaps more subtle, signals that inform individuals whether their present circumstances are benign or threatening. Like affective states, these supplementary signals may also lead individuals to expand conceptual attention when they convey that the situation is safe, and to constrict it when they convey that the situation is unsafe. In the last decade, there has been an explosion of research investigating this proposition. Overall, this work has revealed a great deal of evidence suggesting that a variety of nonaffective situational cues – stimuli that do not involve conscious feelings of pleasure or displeasure, but that nonetheless inform individuals of benign versus threatening situations – moderate the scope of conceptual attention. The nonaffective cues that have been most extensively explored include engagement in approach and avoidance-related motor actions, virtual enactment of approach and avoidance behaviors, and incidental exposure to colors associated with safety versus danger. Research on the effects of each of these types of cues on conceptual attention and creativity will be discussed in turn.

Approach and avoidance-related motor actions

Numerous theorists have proposed that over the course of the lifetime, pulling the arm toward the body (arm flexion) is predominantly associated with approaching desired objects,

as when eating palatable food or hugging a friend. It is also linked to the offset of painful stimulation, as when withdrawing one's hand from a flame. Correspondingly, pushing the arm away from the body (arm extension) is predominantly associated with avoiding undesired or noxious objects and is linked to the onset of pain, as when touching a flame.

Recently, it has been hypothesized that by virtue of the habitual associations between approach-related arm contractions and positive outcomes, and between avoidance-related arm contractions and negative outcomes, that mere engagement in such contractions may be sufficient to tune the scope of conceptual attention much as do positive and negative affective experiences.

To empirically assess this possibility, researchers have asked individuals to perform arm motor actions analogous to those used in acquiring desired objects or rejecting undesired objects by having them lightly yet steadily press their hands upward (approach) or downward (avoidance) against a platform. To prevent individuals from consciously inferring the meaning of these actions, which might bias the results by leading them to deliberately try to (dis)confirm the hypotheses, participants have typically been provided with the cover story that their arm contractions were intended to produce differential brain hemispheric activation and that the experimenters would be analyzing the effects of this activation on their subsequent task performance. Afterwards, while engaging in either arm flexion or extension, individuals have been administered a number of tasks meant to gauge the breadth of conceptual attention.

Studies using this basic paradigm have yielded a number of provocative findings. For example, one recent experiment examined the differential influence of approach and avoidance-related arm motor actions on conceptual scope using a part-list cuing recall task. In such tasks, individuals are provided with a number of word lists to memorize. Each word belongs to one of a predetermined number of familiar categories such as fruits or vegetables. After attempting to commit the words on a given list to memory, individuals are presented with a subset of the words, including a varying number from each category, to be used as cues to help them recall the remainder of the words that were presented. A host of prior studies have revealed that in recall tasks such as this, the more retrieval cues that are selected from a particular category of words, the more difficulty individuals have remembering the remaining words in that category.

Part-list cuing inhibition of this type has been explained in terms of processes of conceptual attentional selection. Essentially, it has been argued that when an item from a categorized list is offered as a cue, this leads individuals to first retrieve their memory of this cue. This act of cue retrieval has been posited to involve narrowing the spotlight of conceptual attention upon the stored memory of the cue, a process that as a collateral effect leads to the inhibition of the memories of items that are closely related. This process is adaptive because it prevents accessible related items from interfering with efficient retrieval of the target item. As an intuitive example, when trying to retrieve the word 'lemon,' it would be helpful if the names of similar fruits (for instance, 'apple,' 'orange,' or 'lime') were diminished in their accessibility such that they would not compete for selection.

In light of this reasoning, it has been hypothesized that nonaffective cues associated with safety, such as arm flexion, relative to those associated with danger, such as arm extension, may attenuate part-list inhibition by reducing the extent to which conceptual attention is honed upon the retrieval cues provided. Consistent with this idea, it has recently been found that part-list inhibition, again, shown by an impaired ability to recall words cued by members of the same category, was all but eradicated among individuals led to flex their arms during retrieval, whereas it was left entirely intact among those led to extend their arms during retrieval. These findings have been replicated several times using other assessments of conceptual scope, including but limited to related measures of memory blocking. Moreover, in none of these studies has there been any evidence that the manipulation of arm motor actions reliably influenced conscious emotional experience, suggesting that the effects at issue are nonaffective in nature. These effects have also remained significant after statistically controlling for variation in the subjective effortfulness of the arm actions as well as for task enjoyment. Therefore, there now exists fairly consistent evidence that approach motor actions, as a form of bodily 'benign situation' cue, compared to avoidance motor actions, as a form of bodily 'threatening situation' cue, broaden the scope of conceptual attentional selection.

In light of these findings regarding conceptual breadth, the question naturally arises as to whether approach relative to avoidance motor actions correspondingly enhance creativity. As discussed earlier, a broadened scope of conceptual attention should bolster the ability to produce innovative solutions by facilitating activation of material in memory that is relatively inaccessible to awareness. To test this, researchers have had participants engage in arm flexion or extension while they completed well-known creative insight problems, such as the following:

A dealer in antique coins got an offer to buy a beautiful bronze coin. The coin had an emperor's head on one side and the date 544 BC stamped on the other. The dealer examined the coin, but instead of buying it, he called the police. Why? *Solution:* The year 544 BC predates the birth of Christ; therefore, a coin from that year would not be inscribed with an abbreviation for 'Before Christ.'

In this problem, despite the fact that virtually all participants know what BC stands for, this knowledge is only weakly accessible to consciousness in part because it is unnecessary for understanding the problem. For this purpose, knowledge that BC signifies a year occurring prior to AD 1 or merely denotes a time of antiquity is sufficient. Therefore, it may be posited that an expanded scope of conceptual attention should help activate knowledge of BC's literal meaning, thereby facilitating solution.

Consistent with this prediction, individuals who engaged in approach, relative to avoidance, motor actions were found to show an improved ability to solve creative insight problems of this variety. Notably, these nonaffective cuing effects have been replicated using creative generation tasks as well. For instance, in one study, participants performed arm flexion or extension while they completed a variant of the Torrance alternative uses test. Specifically, participants were given a minute to list as many creative uses for a brick that they could think of, refraining from typical uses or uses that were virtually impossible.

Afterwards, their responses were independently judged with respect to their creativity. It was found that individuals who had engaged in approach, relative to avoidance, motor actions generated more original uses, controlling for fluency (the sheer number of responses tendered). This convergently supports the notion that nonaffective safety, relative to danger, signals expand the scope of conceptual attention, facilitating entry into consciousness of the unconventional associations that inspire innovative solutions.

Critically, if arm flexion bolsters creativity by broadening the scope of conceptual attention, rather than simply enhancing task motivation, then it should also undermine performance on tasks that benefit from narrowed conceptual scope. Analytical reasoning is a domain of problem solving that involves carefully focusing attention upon the premises given and logically deriving conclusions from these premises. Therefore, whereas activation of material that is remotely associated with the information given may facilitate creativity, in the case of analytical reasoning, activation of remote associates does not bolster task performance and may indeed disrupt it by fostering distraction. Accordingly, it has been found that engagement in approach, relative to avoidance, motor actions impairs, rather than enhances, the ability to solve analytical reasoning problems (akin to those included on the GRE Analytical exam or LSAT). This supports the contention that nonaffective safety, relative to danger, signals do not merely bolster task motivation, but expand the breadth of conceptual attention, undermining performance when the task at hand requires concentration upon a limited set of information.

Virtual enactment of approach and avoidance-related behavior

Researchers have also examined whether the mere thought of approaching a reward versus avoiding a threat may suffice to trigger the processes of attentional tuning posited to influence creative thought. While such thoughts may not lead to affective arousal, they may nonetheless moderate the scope of conceptual attention due to their cognitive association with benign versus threatening situations. Researchers have investigated this possibility by administering to participants paper-and-pencil maze tasks in which a cartoon mouse was to be led through the maze to find a piece of cheese or to escape a hovering owl. 'Virtual' enactment of approach and avoidance behaviors via maze completion was not found to affect emotional experience. This is unsurprising given that it only entails 'helping' a cartoon rodent obtain an imaginary incentive or avoid an imaginary threat. However, since maze completion does activate material in long-term memory related to actual safety or danger, it was predicted to influence attention much as do arm flexion and extension or happy and anxious feelings. Restated, virtual approach enactment (safety-related signal), relative to avoidance enactment (danger-related signal), was hypothesized to broaden conceptual attention and to enhance creativity.

This proposition has received support from several studies. For example, in one study, individuals were administered either the approach or avoidance maze task followed by a Stroop task. In this task, participants are exposed to a series of color words that are printed in either congruent colors (e.g., 'blue' printed in blue) or incongruent colors (e.g., 'blue' printed in yellow). They are instructed to identify as rapidly

as possible the color in which each word is printed. Since there is an automatic tendency to read a word to which one is exposed, in cases of incongruent coloring, individuals are forced to choose a non-dominant response (naming the color of the print, instead of the identity of the printed word). This may be hypothesized to benefit from a broadening of conceptual attention, as this would increase the accessibility of nondominant responses. Therefore, since benign, relative to threatening, situation cues are posited to expand the scope of attention, they should improve Stroop performance on incongruent trials. This prediction was borne out using the cheese and owl maze tasks – virtual enactment of approach behavior speeded responses to incongruent Stroop trials relative to virtual avoidance enactment. There were no performance differences between the approach and avoidance groups on congruent trials, indicating that the aforementioned effects were not a simple result of differences in effort. In related research, virtual enactment of approach versus avoidance behavior has also been shown to affect creativity, with incentive versus threat-related maze completion engendering an improved ability to produce original alternative uses for an object with a pre-established function (for instance, a brick).

Color-based signals

Another type of nonaffective cue that has been found to influence attentional breadth and creativity is incidental exposure to distinct colors. According to theorists, the color red often, if not invariably, signals danger. For instance, it is frequently used to mark errors on homework by instructors and to signal traffic hazards, as in stop signs and road flares. It is also a non-verbal signal of anger in humans and other species. In light of this common association, it has been proposed that when the color red is salient, at least in performance settings, it prompts the goal to avoid threats. This in turn leads to a constriction of the scope of attention, which ultimately eventuates in diminished creativity. Of course, just as red signals danger, other colors are more typically associated with benign or safe situations. For example, it has been proposed that the color blue is often, if certainly not always, associated with tranquility (as in the classic song lyric, “nothing but blue skies from now on”). This common association correspondingly enables it to function as a nonaffective safety cue, exposure to which expands conceptual attention and facilitates creativity.

To empirically assess these ideas, researchers have unobtrusively exposed individuals to either the color red or blue by altering the background hue of their computer displays or placing differentially colored swaths of paper on their test instruction packets. Studies have revealed that on tasks that presumably benefit from narrowed attention, individuals exposed to red outperformed those exposed to blue. For instance, they were better at determining whether pairs of identical or highly similar stimuli were exactly the same or not, a task that demands careful attention to the information provided. In complementary fashion, exposure to blue, relative to red, has been repeatedly demonstrated to broaden the scope of conceptual attention and promote creativity, as shown by improved performance on the RAT and an ability to generate more creative alternative uses. In a particularly intriguing recent study, participants were provided with pictures of a number of different toy parts and asked to design a novel

children’s toy using some subset of these parts. Remarkably, when the parts were depicted in blue, individuals produced toys that were independently rated as more original in design than when the parts were depicted in red. Notably, consistent with the view that these findings are nonaffective in nature, none of the reported studies on the effects of color on attentional scope and/or creativity have found that the color stimuli differentially influenced mood or transient emotional experience.

Attentional priming

Although affective and nonaffective safety and danger signals are the most intensively investigated types of attentional tuning cues, researchers have recently turned their efforts to identifying other types of situational factors that may influence the scope of conceptual attention and, with it, creativity. One such factor is the scope of perceptual attention, the amount of sensory information that is selected for processing. A number of theorists have proposed that the mechanism used to select which perceptual stimuli will occupy the focus of attention is the same as, or at least strongly associated with, the mechanism used to select which of the conceptual representations (e.g., facts, expectancies, images) stored in long-term memory will be brought to mind. Building on this notion, it has been hypothesized that changes in the scope of perceptual attention may elicit corresponding changes in conceptual attentional scope. More precisely, expanding or contracting the scope of perceptual attention, by focusing on a broader or narrower area of sensory space (e.g., a larger or smaller visual area), may in turn increase or reduce the amount of information activated in long-term memory. With regard to creativity, it follows from this reasoning that by inducing individuals to focus on a wider versus more constrained area of visual space, this should momentarily narrow conceptual scope, impairing creative thought by impeding access to remote associates.

This ‘attentional priming hypothesis’ has found support in a recent series of experiments. For instance, in one study, participants were presented with a series of 1 s computerized displays, each containing a set of nine digits. The number three was presented in half of these displays and participants were tasked with indicating as quickly as possible whether a three was present or not. To manipulate the scope of perceptual attention, in the broad scope condition, digits were scattered about the periphery of the computer display, requiring that participants search a wide area of sensory space. Correspondingly, in the narrow scope condition, digits appeared within a 2-in. radius of the center of the display, requiring that visual search was limited to a constrained area. Afterward, participants were administered two creative generation tasks, one in which they were asked to generate creative alternative uses for a brick and another in which they were to devise a creative title for a humorous photograph (of a dog holding a bagel in its snout). Consistent with predictions, individuals who were led to focus perceptual attention broadly versus narrowly, showed greater originality on these tasks, as judged by a set of independent coders. These results were replicated using different manipulations of perceptual scope, for instance, by having participants focus on wider versus narrower areas of geographical maps. They were also replicated using different measures of creativity, including an

exemplar generation task on which participants were asked to provide as quickly as possible the most unusual exemplar of a given category (e.g., birds, sports) that they could think of. While such findings require additional corroboration, they do suggest that subtle, situationally-elicited changes in the focus of sensory attention may at least transiently influence access to the cognitive material required to produce innovative solutions.

Conclusion

In sum, recent research building upon the seminal ideas of associative learning theorists has suggested an integral link between the scope of attention and creative thought. Specifically, it has been proposed that an expanded spotlight of conceptual attention facilitates awareness of relatively inaccessible or peripheral information, thereby bolstering the ability to produce innovative alternatives. This notion draws support from personality research showing that traits associated with a diminished tendency to inhibit irrelevant information predict creative achievement. It is also supported by a range of evidence demonstrating that situational cues associated with safety broaden conceptual attention and bolster originality, whereas cues associated with danger narrow conceptual scope and impede originality. Cutting-edge research has also suggested that situationally induced expansions or contractions of perceptual focus correspondingly facilitate or inhibit access to the remote associates used to generate creative alternatives.

While research over the last decade has yielded a number of provocative findings regarding the role of attentional processes in creative cognition, many important questions remain almost entirely unexplored. Researchers are currently investigating the limiting conditions of the effects of attentional scope on creativity, as well as exploring potential moderators of these effects, including motivational intensity, differential hemispheric activation, and social power. Whatever conclusions ultimately emerge from this ongoing research, it seems increasingly likely that in the coming years, many of the primary factors that influence creative thought will be identified, and their roles elucidated, using the theories and methods of psychological science.

Glossary

Adaptability Organizing to change routines deliberately. Characterized by anticipating problems and developing timely solutions, staying abreast of new methods with prompt and widespread acceptance of change.

Brainstorming A divergent thinking technique to generate ideas that encourages quantity, hitchhiking and freewheeling with no criticism allowed.

Convergent thinking Selecting best options from a broad range of possibilities.

Deferral of judgment Withholding judgment to allow for divergent thinking. Keeps divergent and convergent thinking separate.

Divergent thinking Generating information without applying judgment and without analyzing.

Efficiency Organizing for routine production; doing the routine well.

Flexibility Organizing to cope with temporary interruptions to routines, unpredictable work overloads or emergencies; 'fire fighting.'

Fuzzy situation An undefined problem or situation viewed from a deliberately neutral position.

Ideation-evaluation A two-step creative thinking process sequencing divergent thinking and convergent thinking.

Simplex A circular four-stage, eight-step process of creative problem solving involving ideation-evaluation in each step.

What Are Attitudes?

The concept of attitude has been a fundamental construct since the beginnings of systematic research in social psychology and has evolved into a field shared among various social sciences including sociology, organizational behavior, educational psychology, communications, political science, and marketing. Despite the long history of attitudes and attitudinal processes research, there is no consensus on precisely what an attitude is and how it can be identified. There is a general understanding that an attitude has, at its core, an element of evaluation. One might describe attitudes as summary judgments of a stimulus, object, or event which aid individuals in structuring their complex environments. As such, attitudes can be seen as items of social knowledge, built from experiences, beliefs, and feelings generated by an attitude object.

The literature suggests that attitudes consist of three response types: affective, cognitive, and behavioral. That is, an attitude consists of how we feel, what we think, and what we are inclined to do about something. This represents the so-called tripartite model of attitudes. Though related, there is evidence that the three types of responses are different. Thus an attitude could be thought of as the categorization of a stimulus object along a continuous evaluative dimension based upon three classes of information: (1) cognitive information; (2) affective information; and (3) experience information concerning past behaviors, separately or in combination.

The literature also suggests a one-component view, which proposes that affective responses to attitude stimuli or objects are based solely upon cognition. Describing the attitude concept as cognition is another way of stating that attitudes are, in fact, items of knowledge; however, it must be recognized that this knowledge has an important experiential base, heavily characterized with emotions and driven by how the individual has responded to the stimuli in the past. Thus the single component and tripartite views are not completely dissimilar.

Unlike personality, attitudes are expected to change as a function of experience, and there is evidence that attitudes based on direct experience predict behavior better than those based on indirect experience. There are numerous theories of attitude formation and change, including consistency theories, self-perception theory, persuasion, social judgment theory, balance theory, and processing models. Processing models are used to explain that true attitude change results when both affective and cognitive processing of information occur in parallel. Some attitudes are much easier to change than others. Trying to change a person's commitment to a long-held position, such as the value of family, religion or politics, is more difficult than changing one's perception of a new brand of chewing gum. Individuals' attitudes related to their creativity represent one such position which may be difficult to change. Such creativity attitudes have conceivably 'worked' for them in their life or career progression. As ego-involved attitudes, they represent parts of one's 'self-picture' and are often closely held.

However, there are ways to positively impact peoples' attitudes toward creativity without threatening their self-image and instead expanding their skills in using their personal creativity. For example, educational studies have consistently found that elementary school teachers typically have negative attitudes toward students with personality traits associated with creativity. However, experiments have demonstrated that creativity training can positively impact such teacher attitudes. Later in this article additional examples of creativity attitudes and change are provided.

The Importance of Creativity to Organizations

The importance of creativity to the well being of society is clear when one considers the degree to which globalization and economic conditions require individuals and organizations to adapt their resources to changing demands to remain

competitive. Creativity can facilitate and increase problem solving and adaptability skills. While many organizations pay lip service to creativity, the most effective organizations recognize its importance and develop positive attitudes toward it. Effective organizations are simultaneously efficient and creative. The efficient organization follows well-structured, stable routines to deliver its products or services in high quantities with high quality and at low cost. It reacts quickly to unexpected turns of events to maintain routines with minimal disruption and without becoming mired in bureaucracy. In a stable world, efficient organizations may be successful. But in a changing world, organizations also need creativity as an ongoing process.

While organizational efficiency implies mastering routine, organizational creativity requires mastering the process of deliberately changing routine. Organizational creativity is a proactive process: it allows the organization to deliberately and continually change and adapt. It entails deliberate discontent – discovering new problems to solve, finding new things to do, and adopting new technologies and methods before anyone else. Adaptability is disruptive. It requires looking outside the organization for new opportunities, problems, trends, technologies, ideas, and methods that may dramatically improve or completely change routines or introduce completely new products and services. Creative organizations anticipate problems and opportunities, and develop timely solutions and new routines. They deliberately and continually change routines to improve quality, raise quantities, reduce costs, and stay ahead of competitors. The people in such organizations exhibit positive attitudes and behaviors consistent with creativity. They accept new ideas and solutions promptly and the acceptance is prevalent across the entire organization. In short, they have a positive mindset, which includes positive attitudes toward creativity and creative work. This article focuses on increasing understanding of how attitudinal factors contribute directly to organizational creativity, as well as demonstrating how organizations can deliberately incorporate creativity into their culture, rather than just talk about it.

Organizational Creativity as a Process Requiring Positive Attitudes

Organizational creativity can be portrayed as a continuous, dynamic, circular three-phase process of finding good problems, solving them and implementing good solutions (see Figure 1).

Creative organizations demonstrate a positive attitude toward problems. In fact, they seek them out as opportunities for disruptive change. Unfortunately, in lesser organizations the word 'problem' is often perceived negatively. In the creative process of Figure 1, problems are anticipated and sought proactively. They are viewed with a positive attitude as opportunities for innovation and improvement. As solutions are implemented, new problems or opportunities are discovered. For example, top Japanese corporations place newly-hired research and development scientists and engineers into sales departments to begin their careers. The intent is for them to learn experientially how to discover the problems of the customer, and recognize that such learning is the beginning of innovation.

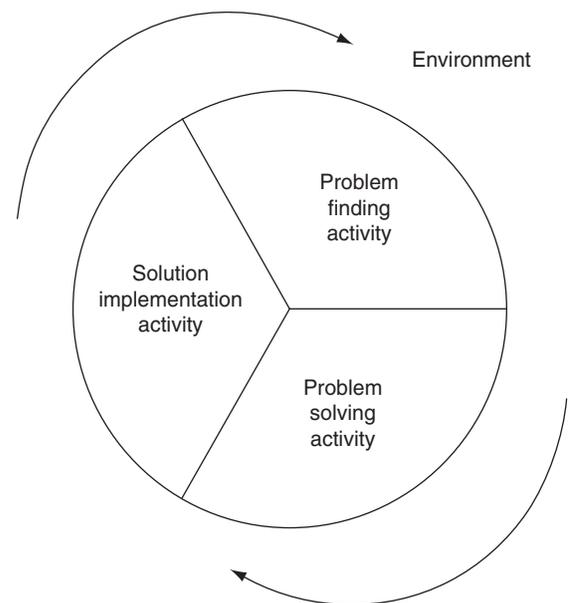

Figure 1 Creativity activity in an organization.

Thus, a positive mindset toward creativity begins with a positive attitude toward problem finding, meaning the behavior of continuously and deliberately discovering and formulating new and useful problems to be solved. In organizations, this includes anticipating new customer needs to generate new products or services, discovering new ways to improve existing products, services, procedures and processes, and identifying opportunities to improve the satisfaction and well-being of organizational members and pertinent groups outside the organization. On the other hand, problem solving means developing new, useful, imaginative solutions to these problems. Solution implementing means implementing such new solutions for successful change. Each implemented solution leads to new, useful problems to be discovered – hence the circular process. Research shows that effective organizations do what it takes to mainstream such a process (make it an everyday habit among its members) for continuous innovation and for intrinsic motivation. Positive outcomes for employees from increasing organizational creativity include greater motivation, job satisfaction and teamwork.

Research on Creativity Attitudes

It is important to realize that the study of creativity from any standpoint can be difficult and complex. For one thing, there is no single agreed upon definition of creativity. Another reason is that creativity is multi-faceted because so many factors contribute to its development and expression. These factors can be classified as personal (such as cognitive, motivational, and attitudinal), social, and environmental. While there is no lack of theorizing about attitudes associated with creativity, there has been only a small amount of empirical research attempting to operationalize these theories. Those few empirical studies can be divided into two different levels of analysis: macro and micro. Macro level studies investigate the role of attitudes

toward creativity at the organizational level while micro level studies attempt to understand their role at the individual level. But first, why has the subject of creative attitudes been so widely ignored in empirical research? One reason might be a perceived lack of applicability. Surprisingly, many researchers seem unaware of already existing research that establishes the significant role attitudes play in creative performance. However, a more likely reason is that changing attitudes of any kind is not an easy task. Perhaps no area of research in social psychology has been as active as the formation and change of attitudes. In fact, in many areas of study other than creativity, the linkage between attitudes and behaviors has been the subject of considerable research and controversy. The belief that attitudes have important implications for behavior in organizations is implicit in various areas of human resource research. Various balance theories predict that individuals who experience inconsistency among their feelings, beliefs, and behaviors are motivated to restore balance. An individual's sense of commitment to an organization as an attitude has been found to have numerous moderators beyond relevant work-related factors. There is only a small direct correlation between an individual's job satisfaction and performance on the job. In short, the relationship between attitude and behavior is complex and is an important area of research. A positioning of this missing relationship in creativity research is an objective of this article.

Macro Level Creativity Attitude Research

Macro level research on attitudes toward creativity can be categorized as being either 'attitudes toward change' or 'attitudes toward creativity.' A variety of measures of personality orientation toward change have been developed to understand the roles various groups play in an organization's adoption of change initiatives. For example, managerial attitudes toward change have been positively related to organizational innovation.

The second category of macro level empirical research consists of a program of field work by creativity researcher Min Basadur and his colleagues, who developed scales to measure the extent to which organizations do not value new ideas, have negative stereotypes of creative people, and whose employees feel too busy for new ideas. These provide an opportunity for innovation-minded managers to enhance creative behavior among staff by nurturing and developing specific positive attitudes. To the extent that employees value new ideas, believe that increased creative behavior and performance can be developed and is not the sole domain of a select few, and feel they are not too busy for new ideas, they are more likely to engage in creative thinking and to try to improve their creative performance.

Some theorists have offered conceptual models explaining how individuals' attitudes play important roles in creativity. For example, some theorists have argued that a negative attitude suppresses creativity but that creativity is enhanced through positive attitude adjustment. Thus organizational processes encouraging positive attitudes toward creativity would be expected to lead to greater engagement in creative activities and to be a requirement for organization-wide creative performance. Finally, some have proposed that a can-do attitude in

an organization's employees during crisis situations is a key factor determining whether or not executives adopt a crisis-as-opportunity mindset, and in turn perceive the opportunity presented in the crisis as attainable.

Empirical Micro Level Creativity Attitude Research

The role of attitudes in creativity can also be understood at the individual or micro level. At the end of the day, creativity is something that a person or team actually does. Creative behaviors produce creative results. Thus, mechanisms by which creative behaviors can be developed or triggered are important for organizations to learn if they truly want to achieve ongoing creativity and organizational effectiveness. In the sections below, empirical evidence is presented that creative attitudes open the doors to, and trigger, such creative behaviors and results. The important linkage between attitudes and behaviors in creativity was identified in field research by Basadur and his colleagues, George Graen and Stephen Green. They summarized the available organizational creativity research into three distinctly different types. The first was identification (of creative people), the second was organizational factors (affecting creativity) and the third was improvement. They undertook a direct test of improving creativity by training and tried to address two major questions: "Does creativity training work?" and "If it does, then how does it work?" Their literature search on improvement turned up seven significant opportunities to advance the research.

First, creativity training as a subset of organizational and industrial training had suffered from many of the problems of organizational training research in general, along with facing some unique problems. Research on 'laboratory training' (i.e., training intended to change behavior and/or skill) had provided no evidence about effects on individuals' problem-solving skills. Only a small number of research studies had dealt with any attempts to teach problem-solving and decision-making skills. Second, those studies that had been done on creativity training were mostly 'nonreal world' or fictitious in nature. Most often they involved asking college students to generate ideas for solving a fictitious, neutral problem such as imagining uses for a wire coat hanger. Only a very few studies concerning real-world problems were found in the literature and much like training research in general, very few had tried to assess behavior change back on the job. Third, most studies showed methodological weaknesses. Fourth, many of the problems in creativity-training research involved measurement issues. Compounding these problems was the difficulty in arriving at even a common definition of what creativity means.

Fifth, there had been no significant investigation of the mechanisms by which creativity training might work. The training had been done on a kind of black box basis; that is, provide training and check to see what came out at the other end, without attempting to find out what was going on inside in terms of intermediate attitudes and behaviors. Essentially, none of the research in creativity training had addressed the intermediate steps of the traditional training model: training develops Understanding to change Attitudes to change Behaviors to achieve superior Results. For example, most of the previous research had tested the brainstorming technique.

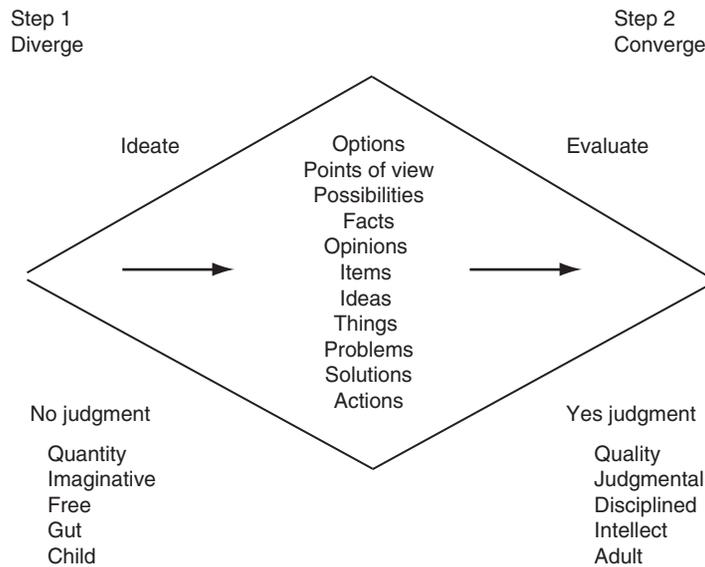

Figure 2 Ideation–evaluation: a sequential two-step creative thinking mini-process.

Brainstorming is the thinking tool most often used for the first half of a two-step thinking process labeled ideation–evaluation (see [Figure 2](#)). The ideation–evaluation process in [Figure 2](#) can be summarized as the deliberate separation of imaginative, nonjudgmental, divergent thinking from nonimaginative, judgmental, convergent thinking. The latter is delayed until the former has had an opportunity to be developed adequately. The emphasis is on doing both kinds of thinking, but separating the two. It is the deliberate use of both ideation and evaluation in a skilled, planned, orderly way.

None of the brainstorming research had attempted to measure to what extent the subjects actually accepted the value of ideation–evaluation and performed it skillfully during the brainstorming experiment or more permanently back in the real-world setting. To what extent brainstorming performance correlated with the attitude of willingness to accept ideation–evaluation and the behavior or skill in using it was never tested. In other words, in many of these earlier research studies, giving brainstorming instructions was all the training there was (as if this was sufficient to obtain sudden changes in brainstorming attitudes and behaviors). It is one thing to ‘nod your head’ to say you understand brainstorming rules. It is an entirely different thing to use the brainstorming rules skillfully, especially on real-world problems on issues that are important to participants.

Several laboratory experiments had indicated that inhibitory influences make training (giving brainstorming instructions) of groups less valuable than training of individuals, however, none of these experiments measured intermediate attitudinal or behavioral effects of such training. It seemed not only unlikely that simple brainstorming instructions would qualify as sufficient training, but also that many group participants would truly accept and use those instructions. They were more probably inhibited within the group and collectively lacked sufficient attitudes and skills in the ideation–evaluation mechanism. These groups should be called untrained, undertrained, or underdeveloped groups. Unless trainees significantly increase their acceptance of and skill in ideation–evaluation, neither they nor their groups should be

expected to improve their creative performance compared to untrained individuals or untrained or nominal groups. In other words, training in creative problem solving must be of sufficient quality, impact, and duration to effect real improvements in attitude toward (acceptance of) the mini-process of ideation–evaluation and its application (behavior). This line of thinking may explain why so few new management techniques become permanent and why many earn the ironic label of flavor of the month.

Sixth, among the few real-world creativity-training studies available, results had been conflicting. For example, one study suggested that such training is useful to managers and professionals in improving creative problem-solving performance on real-world problems, while another disagreed and suggested it only leads to ideas which are very similar to those produced without training. However, a major difference between the studies was that one provided much less training (1.5 hours) than the other (10 hours). One might speculate that the briefer training did not provide sufficient training to unfreeze and change participants’ attitudes and behaviors toward ideation–evaluation, or really induce participants to accept or practice the ideation–evaluation process when confronted with a real-world problem, whereas the other did.

Seventh, the value of training in a complete process of creative problem solving appeared virtually uninvestigated. Most studies involved only brainstorming, which is not a complete process of creative problem solving but rather one tool. Brainstorming is the generation of potential solutions without evaluation to a presented, predefined problem. The literature emphasized the need to study more complete processes of creativity. There were two aspects to this line of thought. First, most researchers in creativity agreed that (1) evaluation was an important aspect of the creative process; and (2) there are stages to the creative process above and beyond simply finding solutions to already identified problems. There was some discussion that finding new useful problems to solve is a separate and more important stage of the creative process than finding useful solutions to already

identified problems. To be of value to real world organizations, training in attitudes, behaviors, and skills requires a more complete process of creativity than a simple tool of ideation such as brainstorming.

Attitudes Are Needed to Make the Creative Process Work

Based on this analysis, Basadur, Graen, and Green set out to comprehensively test the effects of applied setting training featuring a complete process using ideation–evaluation in each step and taking into account many of the above described deficiencies in creativity research. The complete process trained, called Simplex, is described below and can be represented as eight ideation–evaluation steps within the four stages of **Figure 3**. The problem-finding phase of **Figure 1** has been divided into two stages – problem generating and problem formulating – and the process is a circular, continuous, four-stage process of generating, conceptualizing (formulating), solving, and implementing.

Ideation–evaluation occurs within each of the eight steps of the Simplex process. Ideation, or active divergence, is the generation of options without evaluation (deferring judgment). Evaluation, or active convergence, is the application of judgment to the generated options to select the most significant options. Separating ideation from evaluation is a vital aspect of this two-step process. This mini-process must be executed skilfully.

The research systematically measured for the first time the impact of creative problem-solving training on individuals

both immediately after training, as well as later, after they returned to work. The researchers conducted a field experiment in which they expected that providing creativity impactful training would improve five variables: (a) acceptance of the ideation–evaluation thinking mini-process; (b) deliberate practice of the ideation–evaluation thinking mini-process; (c) problem-finding performance; (d) problem-solving performance; and (e) solution implementation performance. The first of these five variables is attitudinal, while the second is behavioral. The researchers suggested that these two attitudinal and behavioral variables were necessary antecedents of the three performance variables. Unless a positive change in attitudes and behaviors were achieved – motivating participants to separate divergent and convergent thinking and to deliberately apply divergent thinking – training would not improve ideation performance. The research tried to measure the extent to which a change in acceptance of (attitude) and practice of (behavior) ideation–evaluation could result from training, and the extent to which it could result in a change in performance. This link between training and actual change in acceptance and practice of the fundamental ideation–evaluation process had simply been assumed to occur in previous research. The expected training effects are modeled in **Figure 4**.

Figure 4 offers the starting point of a theoretical model to explain how training increases organizational creativity and innovation. This model postulates that, in order to achieve meaningful increases in problem finding, problem solving, or solution implementation performance and organizational results, the impact of training must be sufficient to increase acceptance (attitudes) and practice (behaviors) of the ideation–evaluation process. For simplicity’s sake, the model excludes

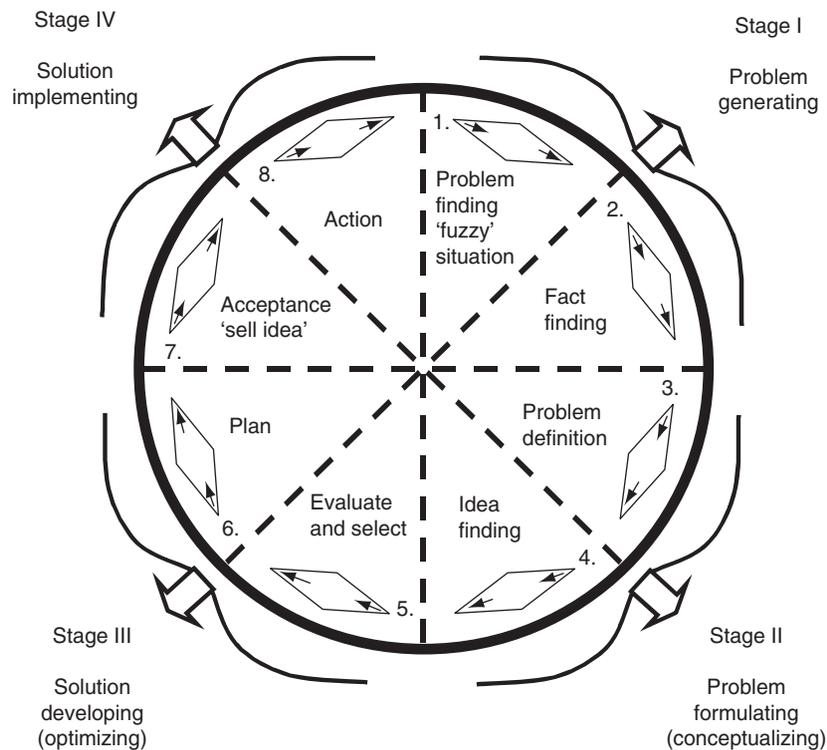

Figure 3 The Simplex creative process as a whole.

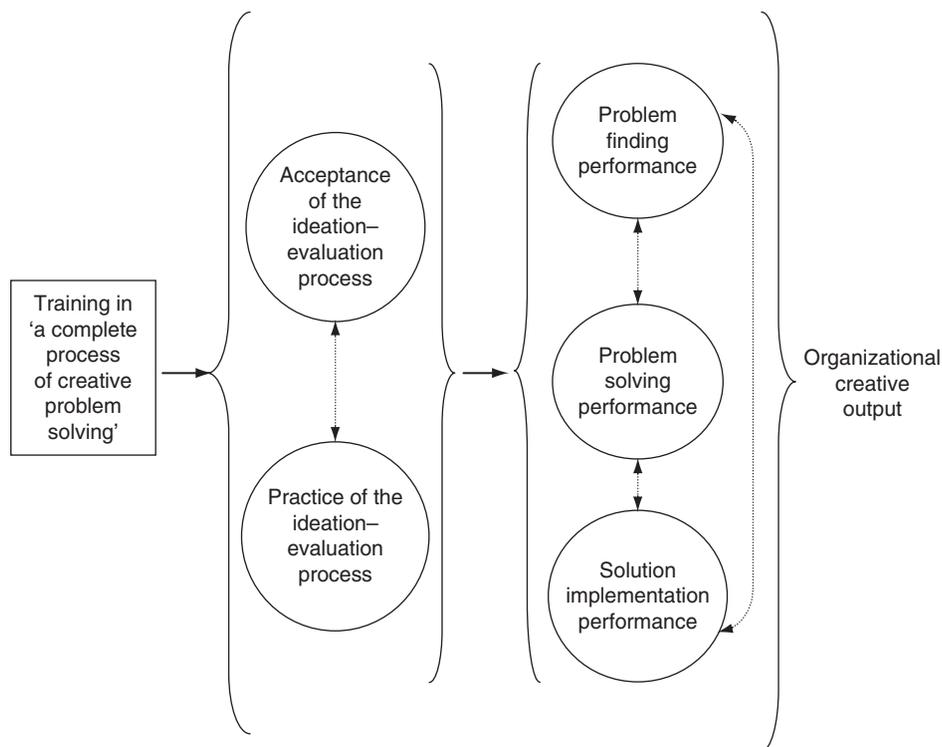

Figure 4 Effects of Simplex training on attitudes, behaviors, and performance.

various organizational, group and individual work-related factors that also affect creativity.

The research explored the effects and mechanisms concerning individual attitudes, behaviors, and performance in a real-world setting (rather than in a laboratory setting). What little previous research had occurred in relatively real-world settings had been limited to group variables. It was also suggested that, compared to simple brainstorming, a complete process such as Simplex would prove more useful and more credible (and less subject to the skepticism that often plagues creativity training) among participants from real-world business and other organizations. Unlike earlier research in which participants were asked merely to apply brainstorming rules without training, Basadur and colleagues stressed the importance of building attitudes and skills through at least two days of hands-on practice using real-world problems.

There were three premises underlying the training. The first was the recognition that, for most people, the ideation step is more difficult than the evaluation step of the process. Our society, including our school systems, tends to reward and hone our evaluation capabilities and preferences and promote their use virtually to the exclusion of ideation. Eventually that results in the dominance of evaluation skills. Engineering students have been found less able to use their imagination upon graduation than they were when they entered school four years earlier. The second premise recognized that, even within the above context, there are individual differences between people's relative preferences, aptitudes, and abilities in the two steps of the ideation-evaluation process. Some people may be relatively better in ideation or in evaluation. The third premise was that the training, while designed to strengthen both steps of the ideation-evaluation process, was

expected to have the most impact on the step of the ideation-evaluation process that was least developed in each trainee.

Research participants included staff drawn from the engineering department of a large consumer goods industrial company. The organization requested the training to promote an increase in creative performance in applied research. Two days of intensive training in creative problem solving (depicted in Figure 3) was primarily experiential and practice oriented and included a series of diverse tasks encouraging participants to discover concepts not considered before, such as ideation-evaluation and the value of both divergence and convergence in thinking. Using a 'learning by doing' model, the training was applied to real-world problems, in addition to case studies. For example, each person generated an individual work problem and then developed a solution and implementation plan before leaving the training session. These processes encouraged transference of creativity concepts to personal frames of reference. Within the design, delayed measures were constructed to reflect attitudinal and behavioral changes transported back to the regular work setting.

Compared to a control group, the experimental training group achieved significant increases in the acceptance and practice of ideation-evaluation and also in the performance variables measured. Multiple method measures, including on-the-job observation, demonstrated that employees made gains in attitudes and behaviors and were seen to be more open-minded to new ideas and approaches, less likely to jump to conclusions as to the nature of a problem, more positive in reaction to new, unusual product ideas, less prone to negative evaluation during idea generation, more capable of generating a good quantity and quality of problems, more likely to consider different problem definitions prior to choosing one as best, and more likely to try new, unusual approaches.

The results supported the model in Figure 4. The model is primarily useful for identifying the key constructs that must be affected in order for training to succeed. In summary, the research suggested that unless attitudes toward divergent thinking are positive or become positive, divergent thinking as a behavior is not likely to be practiced on the job.

Development of Micro Level Creativity Attitudes and Measures

The research by Basadur and his colleagues subsequently led to more precise modeling of how divergent thinking attitudes enhance divergent (ideation) thinking behaviors and skills. In 1985, Basadur and fellow researcher Carl Finkbeiner created measures of two specific attitudes that enhance these process skills. They suggested that the ideation–evaluation process has both attitudinal and behavioral components, and unless the process is accepted attitudinally, it will not probably occur. Using a 14-item questionnaire, they measured two specific attitudes that indicate acceptance of ideation–evaluation: the tendency to (not) evaluate prematurely (preference for deferral of judgment) and the preference for ideation (active divergence). They suggested that these two attitudes enhance and encourage the practice of the two related behavioral skills. Encouraging active divergence leads to generation of more options and deliberate development of many points of view. Encouraging avoidance of premature convergence reduces the urge to prematurely judge or analyze a fledgling thought.

They also suggested that a low tendency toward premature convergence would trigger a high preference for active divergence. That is, the former, more passive attitude is a prerequisite trigger for the latter, more active attitude. When people become skilled in reducing premature convergence and increasing active divergence, they create more, higher-quality options. These two measures of the acceptance attitudes are used in various ways in the research reported in this article as explained later. For example, evidence has been gathered that individuals whose attitudes favor ideation do better on divergent tasks, those whose attitudes reflect a preference for evaluation do better on convergent tasks, while those whose attitudes reflect both perform equally well on both types of tasks. The work is modeled in Figure 5.

Multi-Dimensional Creativity Attitudes

The research has also provided evidence that both the variables of (attitude) acceptance and (behavior) practice of ideation–evaluation are multidimensional rather than single dimensional. One’s attitudes and behaviors in applying the ideation–evaluation two step process probably differ in each of the three–phases of the complete process. For example, someone may prefer to defer judgment and actively diverge in the solution-finding phase more than in the problem-finding phase, or vice versa. Later research provided evidence of different optimal ratios of ideation and evaluation in each of the phases for different fields of endeavor. Thus, six new

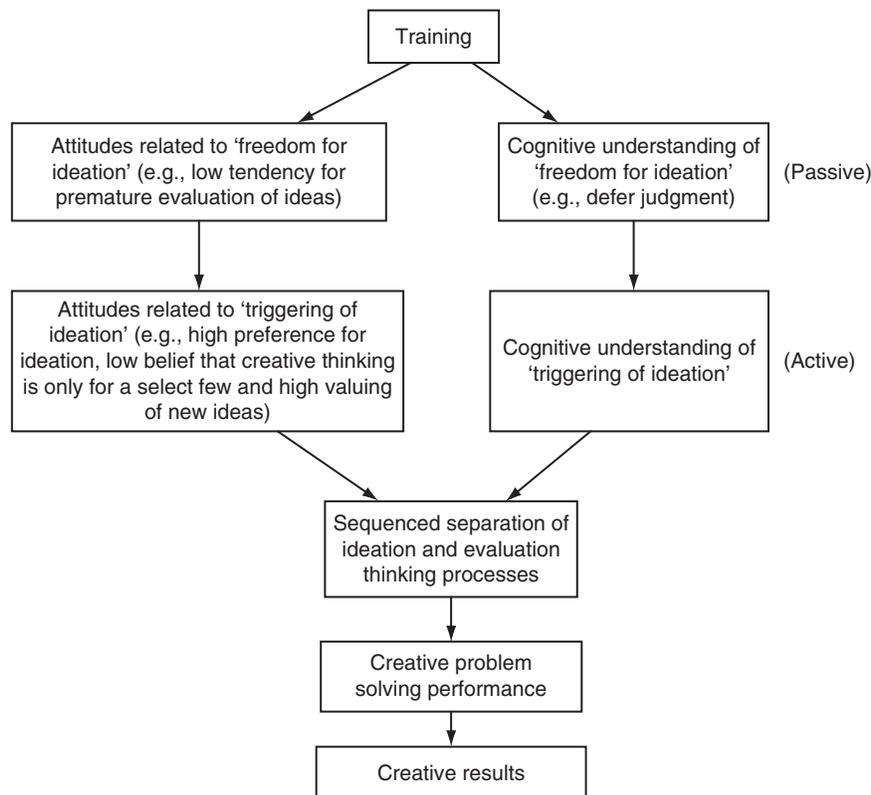

Figure 5 Speculative model of creative problem-solving training differentiating between ‘ideation freeing’ and ‘ideation triggering.’

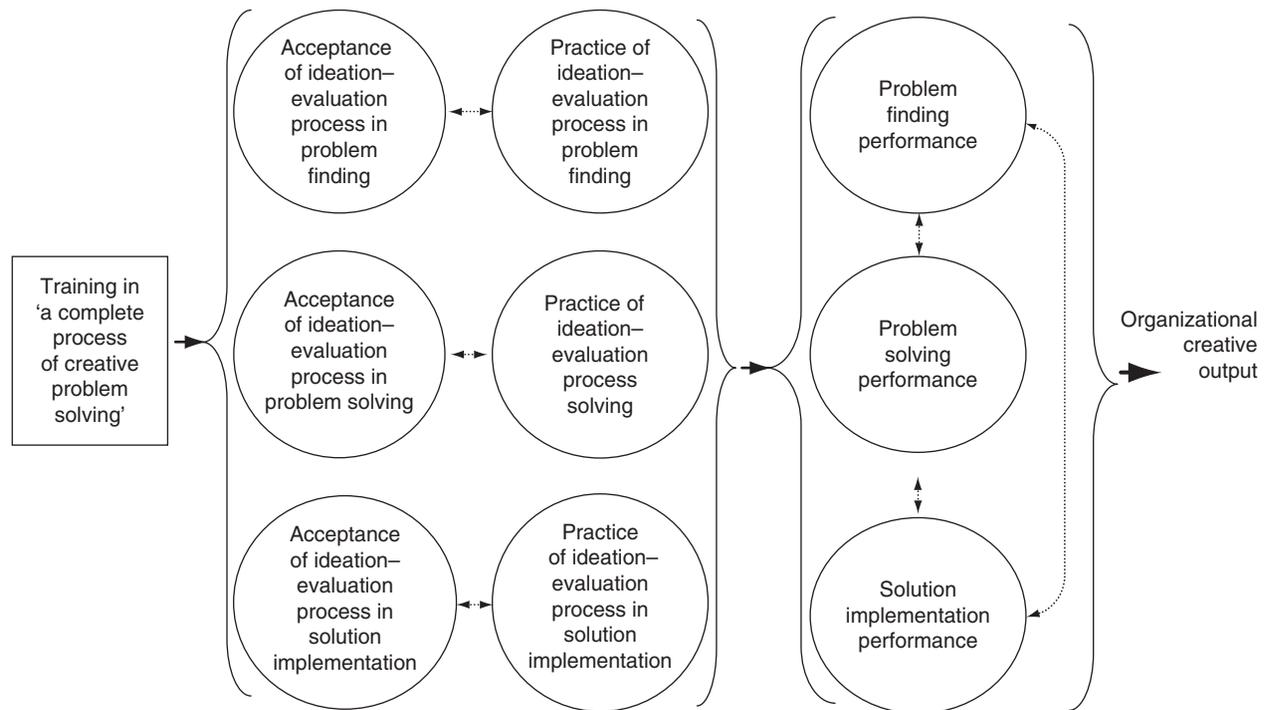

Figure 6 Revised model for training creative behavior in an organization.

antecedent variables replaced the two antecedent variables in [Figure 4](#). The attitudinal antecedents were labeled acceptance of ideation–evaluation in problem finding, acceptance of ideation–evaluation in problem solving, acceptance of ideation–evaluation in solution implementation. Similarly, the behavioral antecedents were labeled ‘practice of ideation–evaluation in problem finding,’ in problem solving, and in solution implementation. The revised model of training effects is shown in [Figure 6](#) which suggests that changes in acceptance of (attitude), and practice of (behavior) ideation–evaluation in each of problem-finding, problem-solving, and solution implementation are necessary antecedents to corresponding changes in performance.

Optimal Ideation–Evaluation Attitudinal Ratios

Basadur and colleagues’ program next began exploring the relative contributions of ideation and evaluation at each of the three phases of the process of [Figure 2](#) in field research. For example, do these relative contributions differ by field of organizational endeavor? Perhaps different optimal ideation–evaluation ratios exist for any job or any organizational function. Perhaps in short-range, time-pressured, high implementation-oriented jobs, evaluation (convergence) is relatively more important than ideation (divergence). Perhaps in long-range, less time-pressured, less implementation-oriented jobs, the reverse is true. Perhaps jobs exist between these extremes in which ideation and evaluation are about equal in importance. Empirical testing was conducted of the idea that fields of endeavor with differing emphases on various phases of the complete creative problem solving process differ correspondingly in the ideation–evaluation preference

ratio of individuals working in these fields. The results supported the notion that people working in various different fields of endeavor in organizations have different ideation to evaluation (I/E) preference ratios corresponding to the varying relative amounts of problem finding, problem solving and solution implementation that their work entails. People working in fields favoring problem finding had higher I/E preference ratios than those working in fields favoring problem solving and solution implementation. People working in fields favoring problem solving had higher I/E preference ratios than those working in fields favoring solution implementation. For example, in manufacturing, characterized by short-term, clear-cut activities leading to action within specific time limits, participants favored an evaluational, converging approach over an ideational, diverging approach. This would be a solution implementation (SI) field of endeavor. In contrast, participants working in environments such as pure research, in which time is a less limiting factor, and action is secondary to understanding, favored a diverging approach over a converging approach. This would be a problem finding field (PF) of endeavor. Between these two extremes were various fields in which, based on problem finding already done by others, one develops solutions for others to implement. Here, moderate time limits for action exist, and favor diverging and converging about equally. This would be a problem solving (PS) field of endeavor including jobs such as administrative or marketing (see [Figure 7](#)).

Changing Creativity Attitudes

Many people who work in organizations may have negative attitudes toward creativity, divergent thinking, and new ideas.

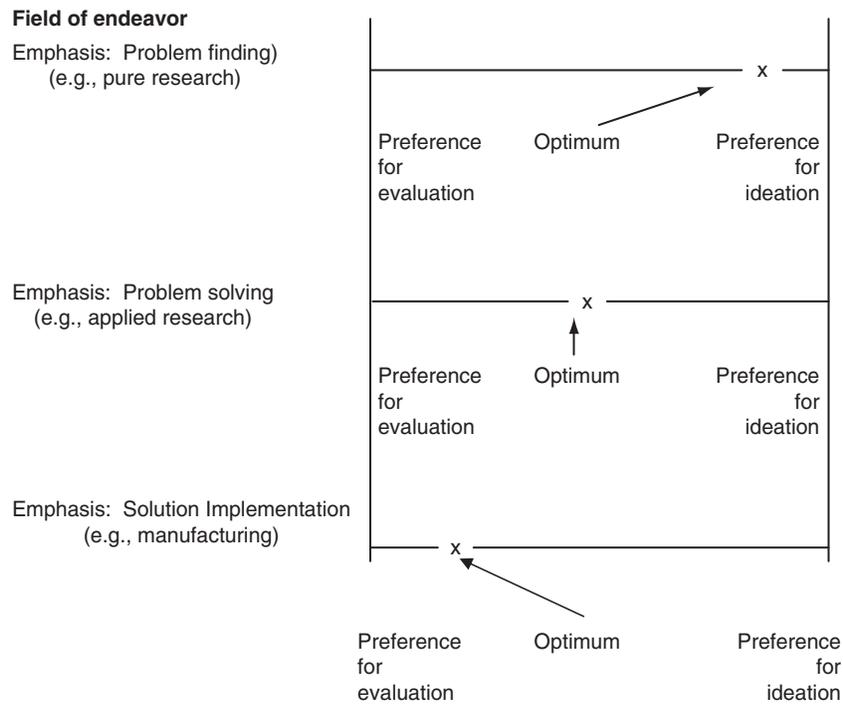

Figure 7 Different optimal ideation–evaluation attitudinal preference ratios for different fields of endeavor.

As a result, employees with more innovative styles are typically viewed with more mistrust and negativity by others. They encounter greater difficulty in getting their ideas accepted because they tend to propose more unusual solutions and may even redefine given problems in unexpected new ways. Others in the organization tend to have negative attitudes toward such divergent approaches inasmuch as the substantial changes they represent evoke feelings of discomfort and apprehension. Unless improvements in these attitudes can be achieved, efforts to increase divergent thinking and creativity may ultimately be fruitless. In 1986, Basadur, Graen, and Terri Scandura suggested that the attitudes of manufacturing engineers tend to be especially negative toward any form of divergent thinking and creative problem solving. They tend to see little room for creativity in their structured, implementation-oriented environment, where practicality is so highly valued.

Changing attitudes of any kind is not an easy task. Perhaps no area of research in social psychology has been as active as the formation and change of attitudes. In the 1986 study, the presentation of a multi-phase, complete process of creative problem solving based on synchronizing divergent and convergent thinking in each phase, was an attempt to persuade manufacturing engineers to engage in divergent thinking on their jobs and overcome their negative attitudes which might be a barrier to their use of creative problem solving. Hence, it was of interest to determine the extent to which the training (as a persuasive communication attempt) was able to effect changes in attitudes and the subsequent ability to incorporate creativity into the repertoire of job-related skills.

The research focused on the two attitudes toward divergent thinking identified by Basadur and Finkbeiner: (a) preference for ideation (active divergence), and (b) tendency to make

premature critical evaluations of ideas (premature convergence). For example, a person with a high preference for ideation (active divergence) in problem solving would probably find value in generating novel and varied solutions, considering multiple points of view and using initial solution suggestions as stepping stones to additional solution possibilities. A person with a high tendency to make premature critical evaluations of ideas (premature convergence) in problem solving would be quick to find a flaw in a solution offered and eliminate it from consideration, would probably display a high need to be decisive, would dislike wasting time with apparently nonproductive trains of thought, would feel each solution generated ought to be evaluated sequentially before proceeding to the next one, would not want to risk making a mistake, would believe there is one best way or one right answer to solve a problem, would have a low tolerance for ambiguity, and would prefer to optimize on one solution rather than explore multiple options.

The researchers hypothesized that training of the manufacturing engineers in the Simplex process (Figure 3) would lead to an increase in preference for ideation (active divergence) and a decrease in the tendency to make premature critical evaluations of ideas (premature convergence) in measurements taken five weeks after the training. The engineers were either trained as part of an intact work group or with other employees from various work units throughout the organization. The final results saw both measured attitudes toward creative problem solving (preference for ideation, and tendency to make premature critical evaluations of ideas) showing positive change after five weeks for the engineers trained in the intact work groups. However, the diffuse work groups showed statistically positive change in only one of the two measures

(tendency to make premature critical evaluations of ideas). Furthermore, there was some evidence of erosion of even the gain on the one measure in the first part after 10 weeks. Based on these results, it is possible that the engineers trained in intact work groups returned to their jobs along with others who had participated in the training and received peer support for divergent thinking in problem solving. In contrast, engineers in the diffuse work group returned to various work units throughout the organization and found less peer support for divergent thinking attitudes. The study showed that appropriate training can result in positive effects even in populations whose attitudes may be difficult to change, and that the use of intact work groups may enhance the impact of training.

A later experiment found that similar training was successful in affecting divergent attitudes in a wide range of employees. It also found that individuals with a natural preference for developing optimal solutions, as opposed to discovering new problems or playing with ideas, experienced significantly greater gains in attitudinal preference for active divergence following training.

Cross-Cultural Research on Creativity Attitude Change

With the development of the world economy and the erosion of cultural walls, organizations are seeing an increasing need for cross-cultural performance. The ability to learn, understand, problem solve and cooperate between cultures takes on greater importance. The more we know of how managers are similar or different in these respects, the more quickly and efficiently organizational creativity can be stimulated. Research into the impact of training on creativity attitudes and results has shown that it can offer the same successes with Japanese and South American managers as previously demonstrated with North American managers.

However, cultural factors can clearly have an impact on creativity attitudes. For example, the impact of training on the active divergence attitudes of Japanese managers was particularly strong. It is possible that the typical Japanese corporate reliance on consensus-style decision making and the value placed on harmony leads to a greater acceptance of the notion of avoiding premature judgment of others' ideas. This aspect of creative problem-solving training might be more compatible with their corporate culture than the process of actively diverging. In contrast, especially strong cultural forces may act against outrightly favoring active divergence on the job, since Japan is a shame culture. In order to save one's face and maintain personal security, one may try to avoid such thinking in particular. Impactful training in creative problem solving could have an especially high potential for improving attitudes toward active divergence under the consensus-and-harmony-oriented Japanese business culture.

Linking Creativity Attitudes, Behaviors, and Skills in a Causal Model

Additional research has demonstrated that training using the Simplex process significantly improves participants' evaluative skills, and those evaluative skills correlate positively with

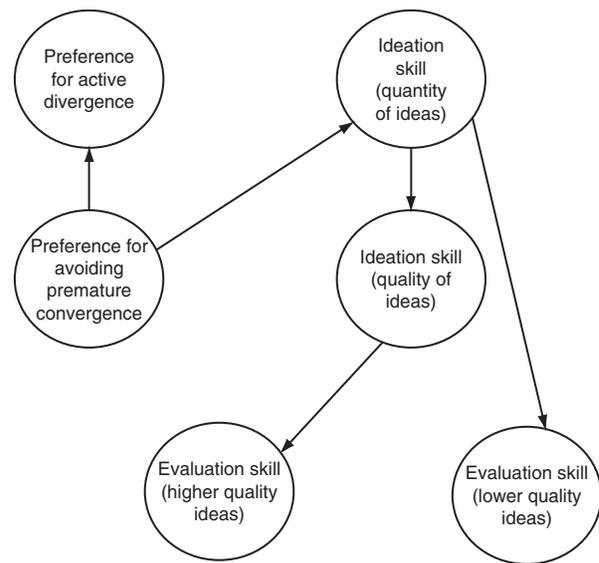

Figure 8 A causal model: how attitudes trigger ideational and evaluational skills.

ideational skills. This result is consistent with the theory that individuals with high ideational abilities have more opportunity to exercise evaluative skills. Additional work has found that the attitude of preference for avoiding premature convergence (deferring judgment) triggers the attitude of preference for active divergence. More importantly, this attitude of accepting deferred judgment is the more powerful attitude, and is significantly associated with the ideational and evaluational skill variables in [Figure 8](#). Increasing the preference for avoiding premature convergence encourages ideational skill in terms of quantity of ideas generated, which in turn translates directly into increased ideational skill in terms of quality of ideas generated and into evaluation skill in terms of more accurately recognizing lower quality ideas. The increased skill in ideation quality then translates directly to increased evaluation skill in terms of recognizing higher quality ideas.

Thus, the key appears to be the attitude of deferring judgment which triggers ideational skill in quantity of ideas generated. This skill, in turn, is strongly related to ideational skill in quality of ideas generated and also to evaluational skills. Interestingly, the increased preference for active divergence, which is triggered by the increased preference for deferral of judgment (avoiding premature convergence) did not play a direct role in enhancing ideational and evaluational skills. However, the possibility of an indirect role remains and raises the possibility of a moderating relationship that could be explored in further research. Additional research ideas follow below.

Future Research

There is ample opportunity for enterprising researchers to further understand the impact attitudes have on creativity at the individual, team and organizational levels while also providing real value to organizations willing to participate in empirical research. For example, the model in [Figure 6](#) invites increased

investigation of attitudes in the problem finding and solution implementing stages of the creative process. Also, no empirical testing has yet been done on the relationship between attitudes toward creativity and personality characteristics such as openness to experience and agreeableness. Given the current popularity of personality research in today's scientific management journals it would seem that this area of study holds much promise to bring creative attitudes to a broader audience. Finally, extending the cross-cultural research to additional important regions such as China and the Middle East would be most appropriate in our rapidly evolving world.

Glossary

Consensus Agreement across a group of people.

Consistency Stability across time.

Covariation principle An effect is attributed to the one of its possible causes with which it covaries.

Dispositional factor Internal causal influence.

Distinctiveness Generalization across situations.

Fundamental attribution error The tendency of the observers to overestimate dispositional causes of behavior and to underestimate the influence of situational factors on behavior.

Self-serving bias The tendency to attribute desirable outcomes to dispositional factors and undesirable outcomes to situational factors.

Situational factor External causal influence.

Introduction

Creativity is a complex process and cannot be understood by just one explanation. It has predominantly been studied in terms of cognitive and personality processes, but recently situational forces have gained attention. Attribution theory is a sociology-based view that aims to understand the reasons for explanations of others' behaviors. Attribution theory, in essence, deals with people's responses to questions beginning with "why?". For instance, when individuals behave aggressively, is it people, their dispositions, the environment, or situational factors that are responsible for the aggressive behavior? If a person behaves creatively, should this be attributed to the person having high creative potential or to the forces of the 'press' that represent situational factors?

Background

Attribution theory was originally developed by Fritz Heider, one of the most important social scientists of the twentieth century. In 1958, he proposed the concept of 'attribution theory' in his book, *The Psychology of Interpersonal Relations*. His studies on social psychology inspired many other scientists, some from different disciplines. Approximately ten years after Heider's outline of attribution theory, Harold Kelley extended it to include cause and effect relations. As such attribution theory can be related to every area of psychology that involves judgment, perception, and thinking. In 1995 attribution theory was applied to creativity by Joseph Kasof in a special issue of the *Creativity Research Journal*. This article details the relevance of attribution theory to creativity.

According to attribution theory, creativity has both objective and subjective aspects. As often defined, creative products must be original, novel, and infrequent. This is the objective part of creativity and originality, novelty and infrequency constitute the main dimensions of many tests of creativity. Objective assessments of creativity are based on normative criteria. One of the main advantages of objective creativity tests is the evaluation of creative products by blind judges. This yields high inter-rater reliability. However, according to attribution theory, use of objective criteria involving such dimensions seems to

fall behind measuring creativity, since creativity does not emerge in isolation. Creative products must also be approved or accepted by the 'judges,' and this is the subjective part of creativity. Kasof argued that objective tests ignore the subjective aspects of creativity by explaining all of the variation in creative performance through individual differences concerning creative ability. He claimed that objective tests tend to reduce ecological validity. Overreliance on objective tests discards the point that reception of original products is socially constructed.

Consideration of creativity as a 'social construct' has at least one significant implication: there can be no objective criteria to measure creativity. Just as with evaluation of physical attractiveness, judgments of creativity also depend on social values. All judges have their own values, which influence their evaluations of the products. Judges – who may be scientists or experts but also laypeople – are the persons that decide whether a product should be approved, accepted, and valued. In 'controlled' studies, researchers decide what is creative and what is not, but in 'uncontrolled' real life settings, creativity is more about social judgment. In this view, even if the individual creativity is assessed, it cannot be thoroughly isolated from the social environment.

In a nutshell, attribution theory underlines 'situational factors' and challenges the conventional theories of creativity which used to focus on 'dispositional factors.'

Dispositional Versus Situational Factors

Throughout the centuries, both researchers and laypeople have attributed creativity mostly to genes, brains, and personal traits. These are all dispositional factors. For instance, Plato defined creativity as an inspiration, a kind of madness. According to Aristotle, the creative process is the product of natural laws; in other words, creativity comes from something that exists naturally. Kant also saw creativity as the kind of genius. He emphasized the unprecedented, spontaneous nature of the creative process. Galton, one of the most eminent scientists of the nineteenth century, extended Darwin's theory to creativity and defined creativity as an inherited ability.

In academia, creativity has been the subject of cognitive and personality psychologists, rather than sociologists or social

psychologists. Creativity first appeared as a concept in psychology literature in Joy Paul Guilford's Presidential Address, which focused on dispositional causes. This tradition has become the mainstream with the contributions of E. Paul Torrance, Frank Barron, Mark A. Runco and many others. When nearly 10000 studies were searched using the terms *creativity, sociology, environment, intelligence, and personality*, there were only ten entries under sociology, 50 under environmental factors, and 59 under cultural issues. On the other hand, there were 222 entries under intelligence, 243 under personality, and 280 entries under ability. Most of the dissertations on creativity also examined it on the individual level instead of the group level. This situation was not different for laypeople. According to most of the laypeople, creativity is a quality of persons and a personality trait and, to a large extent, comes from genes. Thus, people either have it or not, and most of people do not have it. Laypeople mostly do not think that creativity can be a continuum and all people can have it to some extent. This dichotomizing view could be a result of the overall tendency of the field to examine the personal differences between creative and noncreative individuals.

During the past 20 years, Joseph Kasof, Teresa M. Amabile, Mihaly Csikszentmihalyi, Dean Keith Simonton, and other researchers have focused on situational factors as well as dispositional ones. According to those researchers, creativity is not only a product of an individual effort but also a product of complex social systems. Their research indicated the influence of rewards and external motives, field and domain, and political situations and zeitgeist on creativity. Kasof did not negate the relationship between dispositional characteristics and creativity. However, he doubted the direction of the relationship between dispositional characteristics. Contrary to the common assumption, such characteristics can be the results, rather than the causes, of creativity. For example, creative people tend to be contrarian. According to Kasof, contrarianism does not lead to creativity, but creativity may result in contrarianism.

Kasof also explained three basic mechanisms that influence the attributions of creativity, some of which are covariation, salience, and self-serving bias.

Covariation Principle

'Covariation principle' was introduced by Harold Kelley who defined it as attribution of an effect to one of its possible causes with which it covaries over a period time. Covariation principle applies to the situations in which the attributors observed or noticed the effect two or more times. Accordingly, shifts from one kind of behavior to another yield different attributions for different reactions to this behavior. A famous example, known as the prisoner's dilemma, indicated that people's attributions regarding the same behavior pattern of a person can differ depending on the response of the reactant, see Table 1. In one case, a group of people observed two people, one of whom behaved cooperatively and the other also reacted cooperatively. When the first person, in turn, behaved competitively, 84% of the judges believed that the first person was competitive. In the other case, the actions of the first person were the same (cooperative and competitive, respectively) while the reaction was competitive in the second case. A smaller size of the observers (62%) believed that the first person

Table 1 Attributions of judges known as prisoner's dilemma

	Case I		Case II	
	Person I	Person II	Person I	Person II
Turn 1	Cooperative		Cooperative	
Turn 2		Competitive		Cooperative
Turn 3	Competitive		Competitive	
Result	84% judge person A to be competitive		62% judge person A to be competitive	

was competitive. The attribution of being 'competitive' about the first person is higher when the response of the second person is cooperative, than when the response is competitive.

Covariation principle explains the locus and stability of attributions in light of three variables. The first one is *consensus* which refers to generalization across persons. When people make attributions, they tend to consider whether all individuals behave similarly in a given situation. The second is *consistency* which is generalization across time. People often take into account if a person behaves similarly in other similar situations. The third one is *distinctiveness* which is generalization across situations. It explains if a person behaves similarly in different situations. People can know that their judgments are true if the judgment is associated distinctively with the stimulus (*distinctiveness*), if the judgment is similar to the judgments of other people (*consensus*), and if the judgment is consistent over time (*consistency*).

These three criteria are vital for attribution validity, however, they are not equally important. Consensus is more important for attributions of creative behavior than consistency and distinctiveness. The most important characteristic of creative behavior is originality and there is a negative correlation between originality and consensus. If the originality of a creative product increases, its consensus value decreases, and lower values for consensus cause higher internal attributions. Thus, highly creative behaviors are attributed to more internal causes than fewer creative behaviors. On the other hand, noncreative behaviors are attributed to dispositional factors only if the situation strongly supports the creativity.

Influence of number of creators on attributions may be a good example for the *covariation principle* in terms of *consensus*. The greater the number of creators, the higher the consensus and the more likely it is to be attributed to an external cause. Thus, when two or more scientists work on the same product independently, the consensus is higher than when it is made by only one scientist. Multiple creations are attributed less internally than single creations. In addition, if the multiple creators report the same creation at nearly the same time, the consensus will be higher, so the creation is attributed to more external causes. If two or more creators work on the same product at the same time, consensus is again higher than for single creations, so the creativity is attributed to external causes.

For consistency, if people behave creatively in a given situation over and over, their creativity is mostly attributed to dispositional causes. On the other hand, inconsistent creative products are attributed to situational factors, such as having a supportive boss for that time. If the creative product is not consistent, the creator has less of a chance to become

well-known even if the product is really good and valuable. As a result, those with longer careers have more of a chance to become well-known because they have more opportunities to produce creative products than those with shorter careers.

Although distinctiveness is not as important as consensus, it still influences the attributions of creativity. If people are creative in all situations, distinctiveness is lower, so the behavior is attributed internally. But if the creative behavior is common in one situation and rare in other situations, the creativity is attributed to external causes. If a person is creative in different domains, distinctiveness is lower; therefore, creativity is mostly attributed to internal causes. Hence, if two creators create the same number of products, but one's products are in different domains, he or she is considered more creative than the other. Even within a domain, if people use different styles, materials, etc., they are considered more creative than others who use the same styles or same materials. Having information about consistency and distinctiveness affects people's explanations about creativity. Most of the time, however, attributions are made without information about consistency and distinctiveness.

The relationship between these three variables results in different kinds of attributions. Lower levels of consensus and distinctiveness yield internal attributions whereas higher levels for consensus and distinctiveness result in external attributions. Higher levels of consistency tend to lead to more stable attributions. More discrepant levels of consensus and distinctiveness (i.e., higher for one and lower for the other) induce more complex attributions.

Saliency

Saliency plays an important role in the attributions of creativity. For example, think about the music group you like the most. Who might be the most creative person in the group? Most people would answer, "The lead singer." Because singers are more salient than guitarists, bass players or drummers, people perceive them as more creative than the other members of the group. If a poet appears on a TV show, people think that he or she is more creative than other poets who rarely show up on TV.

Saliency can operate in other ways, too. For instance, 'wishing to be alone' is seen as a characteristic of creative persons. Creative persons are considered unsociable, alone, and marginal ones, or unsociable, alone and marginal people are considered more creative than others. In a group, if a person has an unusual hair style or color, wears it different from others and behaves marginally, observers are more likely to believe that he or she is more creative than the other members of the group, even if there is no evidence to support this assumption.

Saliency is also related to the number of creators especially in scientific creativity. Scientific work has become more collaborative; therefore, attribution of scientific creativity to internal causes has decreased. However, while experimental studies are often done by multiple creators, theorists usually work alone. Therefore, theoretical studies are still attributed mostly to internal causes. Similarly, collaborative studies are more common in science than in humanities, so creativity in humanities is mostly attributed to internal causes in contrast to creativity in science.

Actually, the relationship between creativity and saliency is bidirectional. Creative products can also lead to saliency

because creative things are novel, and novel things are usually more salient. People tend to see salient products as a result of the personality of the creators and underestimate the impact of situations. However, there is an observer versus actor difference in saliency. When an individual observes another individual in a situation, the observer perceives the actor as more salient than the situation, but the actor perceives the situation in which he or she is in as more salient than himself or herself. Thus, the observer attributes the behavior more to dispositions than the actor. Of course, this can be due to the fact that creators experience the process, but observers can only see the product. This tendency of observers is known as *fundamental attribution error* or *overattribution effect* which refers to the tendency of the observers to overestimate the dispositional factors and to underestimate the situational factors. It occurs more commonly for creative behaviors than any other behaviors because creative behaviors are more novel and original, so they are more salient than other behaviors.

The relationship between saliency and creativity can also be seen in minority groups. Attributing creativity to people from minority groups is also common since they are highly salient. Therefore, creative people of minority groups are perceived as more talented than their actual performance, not just because of their creativity but also because of their rareness. According to Kelley, who introduced *augmenting principle*, if both inhibitive and facilitative factors of a behavior are present together, the greater causal weight is given to the facilitative ones. However, 'minority' here refers not only to cultural minority, but also to any rareness in number. In an empirical study, two equally creative groups were rated. Observers rated the smaller group as more creative than the larger group. This finding may also imply that the empirical studies about higher creativity among schizophrenics or physically handicapped can reflect a researcher bias. Psychopathologies or physical handicaps yield saliency which might attract researchers' attention more than others.

Stereotypic definitions of creative personalities can also be influenced by saliency effect. When we ask about the personality traits of creative individuals, lay people often describe them as nonconformists, independent, risk-takers, unsocial, and so on. On the other hand, it has been argued that creative people possess more complex personalities whereas people tend to notice the rarely observed and salient aspects. As a matter of fact, Mihaly Csikszentmihalyi, W Ed McMullan, Frank Barron, and others defined the most obvious characteristic of creative people as their complex personality. According to these researchers, creative people can bring together all the possible characteristics of humankind in themselves at the same time without any inner conflict. Nonconformity, independence and risk-taking are also characteristics of creative people, but they are exaggerated beyond reality.

Self-Serving Bias

One of the main concerns of attribution theory is people's judgments about their own abilities, feelings, achievements, etc. People usually attribute desirable outcomes to their personality traits and undesirable outcomes to environmental factors. For instance, reasons for acceptance, rejection, or revision of the articles by journals were asked of 230 authors. They mostly

attributed acceptance to internal causes but rejection and revision to external causes. In another study, students who attributed their theses more to themselves than their advisors evaluated their theses as better than their classmates' theses.

Creativity, as a desirable characteristic, is also mostly attributed to internal causes. In a study, ordinary students received the Remote Associates Test, but half of the students received an easier version of the test than the other students. Of the students who received the easier version, and thus got higher scores than the other group, more believed that the test was fair and objective than did the students who received the harder version and got lower scores as a result. Studies showed that self-serving bias rules in brainstorming activities as well. People tend to attribute others' original ideas in the group to themselves.

Like self-serving bias at the individual level, groups can also take credit for their successes, and attribute failures to external causes. This is called 'group-serving bias.' Especially in the environments where teamwork is more important than individual effort, the locus of attribution shifts from individuals to groups. In other words, people try to explain success and failures of the group instead of their own success and failures. For instance, when a football team wins a game, they attribute success to their group cohesiveness, but if they lose, they attribute failure to external causes such as an unfair referee.

Group-serving bias can influence judges' evaluation. Judges usually evaluate the products of members of their own group as more highly creative than the products of members of other groups. This bias occurs when the group members are in or out of their own environment during the evaluation period. For instance, products created by members of one's own sex are evaluated as more creative than those created by members of the other sex. People from the same nationality evaluate each others' products more highly than the products of others. Kasof exemplified Adolf Hitler who believed that all of the technological, artistic and scientific inventions in history were created by Aryan-Germanic people. Corollary to that, if people from other nationalities claimed that they created something, they just stole it from the Aryans, according to Hitler. Also, if a product says negative things about a group, the members of the criticized group evaluate the product as less creative even if it is evaluated as highly creative by experts.

Further Elaborations

There are other factors that can manipulate our attributions. They are general characteristics, status generalization, and social loafing.

General Characteristics

General status characteristics such as gender, race, age, physical attractiveness, or socioeconomic status affect performance expectations for a group of people. A high level of competence is expected from people with certain characteristics even if there is no previous evidence for the relationship between the specific characteristics and task performance. For instance, articles with females as first author sometimes receive lower ratings than articles with males as first author. The results were more dramatic if the female author was not previously known in the

field. For instance, if an essay or art work is attributed to a physically attractive person, people rate the work as more creative than if it is attributed to a physically less attractive person.

This situation is also related to dying young. If a successful creator dies at an early age, he or she becomes more eminent in the future. This is mostly because people remember them at their most attractive ages. Eminent people, like all of us, lose their physical attractiveness and popularity as they become older. Thus, if they die before their success wanes, people remember them as more creative, not because they are really more creative but because people always remember them with their most attractive appearance and most popular products.

Status Generalization

When people come together to achieve a goal, their out-of-group status also affects their inner-group status. In other words, individuals with high social status have advantages in a wide range of areas, even if there is no evidence that such advantages are deserved. High social status is associated with general expectations of talent. Hence, usually the people who are famous out of the group are assumed to be more creative in the group as well. For instance, if a scientist in a group has won a Nobel Prize, it is assumed that this scientist contributed the most to the group, or in a multiwriter article the contribution of the famous scientist is assumed to be higher than that of a Ph.D. student.

A status based bias is known as the *third party status effect*. If the judges know that other people evaluate a product as creative, their probability of evaluating the product as creative is high. How other judges approve of creations influences one's evaluation of the product. However, the third-party status effect has been demonstrated only with domain-specific status characteristics. High status judges are more effective than low-status judges.

Social Loafing

When people work in a group and the individual effort is not identified, people exert less effort than when individuals act alone. This is called *social loafing*, and it affects the attributions. Groups who attribute their creativity to the unique contributions of each individual create more divergent ideas than groups who attribute success to the group as a whole. Attributing creativity to the whole group rather than each individual sends a subtle message that each individual's contributions are not identifiable. When people think that their contributions are not identifiable, they exert less effort to create new things. If people think that they will be held individually accountable, they will be more willing to see the issues from different perspectives. Of course, if groups are not willing to search beyond the obvious ideas, they create less divergent ideas. Hence, it is a common finding that groups generate fewer creative ideas than individuals.

Groups' lowered performance in producing creative ideas can result from conformity pressure. Group focus attributions may increase conformity pressure. When people work in a group, they mostly ignore their own ideas and try to adopt the majority's opinion because groups have a tendency to reject members who do not fit. Thus, individuals can avoid from

introducing their original ideas. Consequently, groups tend to see issues from only one or two perspectives and come up with less divergent ideas.

Like creators, judges are also influenced by the norms and values of their groups. Group norms have obvious influences on people's behaviors including how people recognize creativity. Csikszentmihalyi stated that creativity can only be understood in light of social norms and values. Although creative products should somewhat deviate from the norms, according to Mark A. Runco, if they are much ahead of their time, they might not be recognized as creative in their time. Some of the most famous writers or artists were not recognized during their lifetimes, but they became eminent posthumously. Due to the deviation of their products from their time, no attention was given to them. Hence, the norms and values of the era is one of the most important determinants of people's judgments about creative products.

But group norms and values do not influence every people to the same amount. The level of being affected from the society is determined by individual's relationship with the group. As their personal identities, people also have social identities which internalize values and norms. If the group is important and meaningful for a group member and social identity is more salient than the individual identity; group norms and values become the primary source of the given member's judgments, and members confirm the judgments of the group. But if the judges' personal identities are more salient than their social identities, they can easily express their own judgments in the group.

The influence of social loafing is more visible when the creative products are judged by a group of judges. If judges know that they will be held individually responsible for their evaluations, their evaluations become more positive than when they know that the evaluations are pooled.

Evaluation

Creativity researchers have evaluated attribution theory in different ways. According to Teresa Amabile, attribution theory indicates some ways to develop more comprehensive work-related or school-related creativity enhancement programs. Most creative training programs aim to improve personal traits (such as creative thinking strategies), but with the help of an attribution theory perspective, creativity enhancement programs can also focus on the facilitative and detrimental effects of environments on creativity and can aim to improve environments to help creativity. On the other hand, Amabile criticized attribution theory for its claim that creators notice the environment when the environment prevents their creativity but attribute all success to their personality when the environment assists their creativity. Amabile's and her other colleagues' findings, however, indicated that people mention environmental factors as much as personal factors, a fact which attribution theory overlooks.

Mark A. Runco was the most critical of attribution theory. He objected to attribution theory for several reasons. First, it does not explain what creativity is; instead, it explains individuals' reactions to the creative products. Judgments can be biased. If they are not true, this does not mean that the product

is not creative; instead it can be creative but not recognized. Second, having a creative idea, sharing it with others and convincing others are all different things. Thus, there must be a distinction between inherent creativity and attributed creativity. Attributed creativity is important for reputation because reputations are estimated by others' judgments. But reputation is not creativity, and people's judgments cannot explain inherent creativity alone. Third, attribution theory can explain the creativity of eminent people, but it ignores the daily creativity, known as *little c*. People who are creative in their daily lives but not eminent can sometimes remain unrecognized. Of course, this does not mean that these people are not creative just because they are not reputable. Furthermore, reputations can also be biased. For instance some highly reputable people may gain people's attention, not because of the creative value of their current work, but because of the influence of their previous work. The ability to communicate and convince others is not a good predictor of the ability to generate creative ideas. Fourth, attribution theory can be applied to creative products and performance, but not to creative processes and potentials. Therefore, according to Runco, attribution theory does not seem to be a resourceful perspective for creativity.

Conclusion

Creativity has often been studied in terms of dispositions. Attribution theory attempts to disclose the other aspect of creativity, which is basically about social reception of original ideas. It proposes that social and situational processes can determine the creativity of the ideas because creativity is not independent of the context in which it emerged. Attribution theory deals mostly (even only) with the subjective interpretations as the causes of people's judgments about creativity. However, subjective interpretations are commonly utilized in the evaluation of creative products. Yet, this does not mean that creativity can only be explained by situational factors; or that dispositional factors do not influence creativity. Creativity is a complex process and it cannot be well understood by just one explanation. Attribution theory simply highlights another aspect of creativity's complexity.

Sri Aurobindo 1872–1950: A Yogi and a Poet

A K Dalal, University of Allahabad, Allahabad, Uttar Pradesh, India
M Cornelissen, Indian Psychology Institute, Pondicherry, India

© 2011 Elsevier Inc. All rights reserved.

Introduction and Early Childhood

Sri Aurobindo had a multifarious personality. Though in his later years he was known mainly as one of the most distinguished spiritual leaders of India, he began his public life as a political activist. He was the first one to push the agenda of complete independence of India from British rule, yet he was essentially a scholar, a poet, a philosopher, and above all, a yogi. He was a profound thinker and a prolific writer. The wide range of his achievements made one of his biographers entitle his book *The Lives of Sri Aurobindo*.

Except for a short period of 6–7 years of active public life as a political activist, Sri Aurobindo seldom made public speeches. He was a very private person and rarely entertained visitors. Even to his close disciples he spoke more in silence than in words. He did communicate, however, in thousands of letters. He devoted the second half of his life to a combination of scholarly work and yoga, developing his vision of an ongoing evolution of consciousness and propounding a new school of integral yoga. He was a gifted writer with amazing fluency who, produced poetry of exquisite beauty, plays, essays, and seminal works on a wide variety of subjects, much of which he cultivated through yoga. He ended up writing the equivalent of close to 20 000 printed pages, though much of this work was published only after his death.

Sri Aurobindo was emphatic in stating that only he could write truly about himself. As a man who lived more an inner than an exterior life, he considered it impossible for others to know about it. In spite of his objections, numerous biographies were written, both during his lifetime and in later years. Though Sri Aurobindo did not believe in biographies, he did correct some of the earlier ones for factual errors. During the early years of his stay in Pondicherry, he also maintained a detailed record of his inner development. This *Record of Yoga* came to light more than 25 years after his death, and its 1500 pages shed a fascinating light on his inner development. These records were written in the manner of laboratory notes, using technical terms and abbreviations which are often difficult to decipher. During the later period, he gave an occasional glimpse of his inner life in his letters and in his poems, especially in the later sonnets and in *Savitri*. Together, all this forms quite a rich source of information about his life.

Sri Aurobindo was born in Calcutta, on 15 August 1872. His father Krishna Dhun was a medical doctor, educated in Kolkata and later in London. He was an atheist, a Darwinian, and a thoroughly Anglicized doctor in British Government service. Sri Aurobindo's mother Swarnalata hailed from a family of Bramho Samaj, a religious reformist group of eastern India, who were deeply influenced by Christian theism. As such, the family of Sri Aurobindo was so much Anglicised that he was given a British middle name and was named Aurobindo Akroyd Ghosh. Dr Ghose was so convinced of the

superiority of British culture that he discouraged the use of his mother tongue, Bengali, in his house. There was a butler and a governess in the house with whom Sri Aurobindo used to talk in broken English. Sri Aurobindo grew up speaking, thinking, and dreaming in English. As he mentioned to a friend, till the age of five he did not know his mother tongue, Bengali.

Education in Britain

When Sri Aurobindo was five years old, he and his two brothers were sent to the Loreto Convent School at Darjeeling, a school meant for children of British officers in India. His father wanted his sons to have a solid British education, and when Sri Aurobindo was seven, he sent him, together with his two brothers, to England for further education. The three brothers stayed with the family of Rev. William H. Drewett at Manchester, with the specific instruction that the boys should not mix with Indians and should be kept free from any Indian influence. Sri Aurobindo was too young at that time to go to school and was taught at home. Later he attended what was one of the best public schools in London (St Paul's). The young Sri Aurobindo was a brilliant student who was consistently amongst the best in his class in English and Latin. The school principle Dr Walker personally supervised the education of Sri Aurobindo whom he found weak in Greek initially. He was rapidly pushed to higher classes, which saved him a few years of school education. He won many literary prizes at the school. His teachers found him hard-working and promising; though with time his teachers commented that he was making less of an effort and hardly maintaining his old level of excellence. Sri Aurobindo later recalled that he was by then at ease in his classical studies and did not think it necessary to labor over them any longer. Instead, he read books not assigned in class: English and French poetry and fiction, European history. His English master was struck by the extent of his reading, and commented favorably on his writing style.

Dr Ghose had asked the Reverend Mr Drewett not to give his sons any religious training, but the boys inevitably absorbed much of the intellectual and moral atmosphere of Christianity. Sri Aurobindo later wrote that Christianity was the only religion and the Bible the only scripture with which he was acquainted in his childhood. He knew nothing about India, its culture and history. He and his brothers were understood by their classmates to be Christians, but they had by then become indifferent if not openly hostile to Christianity. For a while Sri Aurobindo considered himself an atheist before adopting an agnostic attitude.

Meanwhile the financial condition of Sri Aurobindo's father deteriorated and the remittances to support his children's education became irregular and ultimately almost stopped.

It created a very difficult and embarrassing financial condition for the three brothers, who had to survive together on Sri Aurobindo's scholarships. For years they lived a very Spartan life, at times having insufficient food to eat and little money to spend on other necessities.

He and his brothers later moved to London where Sri Aurobindo won a scholarship to King's College of Cambridge University. His competition papers were judged to be the best ever seen by an examiner who happened to be a noted writer (Oscar Browning). At Cambridge, Sri Aurobindo set three major goals for himself. The first was to study for his B.A. degree and prepare for the 'Indian Civil Services' (ICS) examination; the second was writing poetry; the third was to participate in the activities of the *Indian Majlis* and to work toward India's independence. Sri Aurobindo's father wanted his son to qualify for ICS, to be one of the top administrative officials in India. In deference to his father's wishes he sat in the exam and qualified. This also earned him a fellowship which he badly needed to support himself and his two brothers at Cambridge. At King's College Sri Aurobindo acquired great proficiency in Greek and Latin and devoted a great deal of time writing poetry. He could read literature in French, German, and Italian and was involved in the literary circles at Cambridge. He wrote a large number of poems during this period that he included in his first collection years later. Before returning to India as a last requirement for an ICS probationer Sri Aurobindo had to take a horse riding test. He decided not to show up and as a result got himself disqualified. He was by now getting more and more interested in India and in the political movement to liberate it from the British rule. The Indian Majlis was an activist group of Indian students studying in England. Sri Aurobindo was its secretary for some time and he used to give fiery speeches to mobilize Indian students. During the last days of his stay in London Sri Aurobindo joined the 'Lotus and Dragger' society. It was a secret society in which each member vowed to work for the liberation of India, even by violent means. This society was, however, still-born. The police came to know about it and this was probably one other reason which went against his final selection as an ICS officer.

Sri Aurobindo started learning his native language Bengali from an Englishman when he was at Cambridge. He developed a sufficient working knowledge to read some Bengali literature, like Bankimchandra, the revolutionary poet. He also acquired a working knowledge of Sanskrit but was otherwise barely familiar with Indian scriptures and history. His knowledge was largely limited to Max Muller's the 'Sacred Books of the East' series. Another source of Sri Aurobindo's information about India was newspaper clippings which his father started sending him. Increasingly hurt by the attitude of British officers, his father's positive regard of the British was diminishing, and he had begun briefing his sons about protest movements in India.

Life in Baroda

Sri Aurobindo returned to India in the beginning of 1893 after staying in England for 14 years. His father who was eagerly awaiting his arrival died under unfortunate circumstances just

before Sri Aurobindo arrived in Mumbai. While still in England, Sri Aurobindo was offered a job by one of the Indian princes, the Gaekwad of Baroda, and after his return, he worked in Baroda for 12 years, as a teacher, as private secretary to the Gaekwad, and finally as the Vice-principal of Baroda College. Though he stayed in Baroda for a long time his heart was in Bengal which he visited frequently. He also used to visit Deoghar where his mother and younger sister were staying. In April 1901 Sri Aurobindo was married to Mrinalini. Sri Aurobindo brought his wife and sister to Baroda to stay with him.

During his sojourn at Baroda, Sri Aurobindo, as a daily routine, was practicing *pranayama* (breathing exercises). As his friends in Baroda observed, he was remarkably simple in his living. He never complained about the heat of Baroda summers or the chill of its winters. Only on the coldest mornings did he throw a shawl over his shoulders; only on the coldest nights did he sleep under a cotton blanket. His bed, a thin mattress on a cast-iron frame was something on which even a man of very simple means would not sleep. Though he was getting a good salary he was hardly concerned about spending it on himself or saving it. He was detached from these mundane aspects of life. He was better taken care of when Mrinalini was around, but she spent more time in Deoghar than in Baroda. Even when she was there, Sri Aurobindo was mostly absorbed in his studies – he would sit reading for hours at a stretch, his eyes glued to the page, his attitude unchanging, like an ascetic rapt in contemplation, oblivious to the world. He also wrote extensively during this period. He would read or write till after midnight, then get up in the morning and resume where he left off. He used to have a cup of tea, smoke, and then sit at his writing table. Once he began, he wrote slowly but steadily, rarely stopping to strike anything out. If someone spoke to him while he was writing, he may have been disturbed but never let the other person know about it.

Only a half-dozen of the poems he wrote in the first six years in Baroda were retained. In 1898 he put together a collection of the poems he wished to preserve from his first decade of writing. *Songs to Myrtilla*, printed privately in Baroda, contains 21 pieces. About a third of them are written about political and literary heroes: Parnell, Goethe, Madhusudan, Bankim; the rest are on love and romance. After publishing *Songs of Myrtilla*, Sri Aurobindo worked on a long narrative poem based on the story of Pururavus and Urvashi. A little later, he completed another long poem, *Love and Death*, which was based on a story from the Mahabharata "in the heat of . . . 14 days of continuous writing." Sri Aurobindo described the main sources of his inspiration in an essay on Kalidasa, written three years after *Love and Death*. He saw his unusual fluency in writing as a specific sort of energy that was behind all genuine poetry.

Sri Aurobindo's admiration for the Indian tradition grew, and it became increasingly clear to him that the Indian civilization could not regain its full stature as long as India was under foreign occupation. Interestingly, at that time, this was not at all a common view: the Indian elite of those days had widely accepted the superiority of the English culture, and Sri Aurobindo would become the first Indian intellectual who dared proclaim publicly that complete independence from Britain should be the primary aim of Indian political parties.

His increasing political involvement embarrassed his employer, so Sri Aurobindo moved to Calcutta where he became one of the most outspoken leaders of the political movement for Indian independence. His writings brought him in frequent conflict with the British authorities but he carefully chose his language and repeatedly managed to escape conviction. Around this time Sri Aurobindo wrote his famous revolutionary booklet *Bhawani Mandir* with a call to prepare revolutionaries for a freedom movement.

This was the time when Sri Aurobindo was intensely pursuing both, political activities on one side, and yoga on the other. Sri Aurobindo knew from experience that yoga could increase one's mental energy and clarity, and he hoped that yoga could develop other psychological powers, which he intended to use for his political work. During a visit to Baroda in 1907, Sri Aurobindo met a yogi, Bhaskar Lele, who agreed to give him lessons provided he could dissociate himself from all political activities for a while and stay with him. Lele asked him to make his mind blank which he could do the very first day. Within three days Sri Aurobindo managed under Lele's guidance to completely and permanently silence his mind. He wrote about this experience.

It was my great debt to Lele that he showed me this. "Sit in meditation", he said, "but do not think, look only at your mind; you will see thoughts coming into it; before they can enter throw these away from your mind till your mind is capable of entire silence." I had never heard before of thoughts coming visibly into the mind from outside, but I did not think either of questioning the truth or the possibility, I simply sat down and did it. In a moment my mind became silent as a windless air on a high mountain summit and then I saw one thought and then another coming in a concrete way from outside; I flung them away before they could enter and take hold of the brain and in three days I was free. From that moment, in principle, the mental being in me became a free Intelligence, a universal Mind, not limited to the narrow circle of personal thought ... (Sri Aurobindo, 1972: 84)

There are two things noteworthy about this experience. The first is that it was not a fleeting experience but a true realization in the sense that the peace and inner silence never diminished. The other is that the experience of the silent, spaceless, timeless Brahman, the Supreme being, was not at all what Aurobindo had expected or wanted from yoga. Furthermore it did not fit either within the mental framework of his instructor, Lele, whose own experiences were with the personal Divine. During the following weeks Lele still taught Sri Aurobindo how to rely both for his outer work and for the rest of his inner development on an inner guidance, but after that, they parted ways. After this Sri Aurobindo never sought the guidance of a teacher and moved on to develop his own system of Integral Yoga. The presence of the silent Brahman never left Sri Aurobindo, though it subsequently merged with other realizations of the Divine. Initially the experience of the silent Brahman came together with an overwhelming sense of the total unreality of the world, but the latter gradually disappeared when he had the realization of the cosmic consciousness pervading all things and all beings. Interestingly, all this happened during one of the busiest periods of his life while he was at the peak of his political influence, and he managed, in his own words, to organize political work, deliver speeches, edit his newspaper and write articles, all from an entirely silent mind.

As a Revolutionary

By that time Sri Aurobindo was getting more and more involved in the underground freedom movement. He preferred to remain in the background, but he was indirectly involved in recruitment of young people arranging their physical training to prepare them for action against the British. He secretly visited many such revolutionary organizations to bring them under one banner and pool their resources. He became the co-editor of *Bande Mataram*, a political paper aiming at national construction, passive resistance, and self-reliance. He also contributed to another paper, *Yugantar*, which preached open revolt against the British rule.

In the meantime, his younger brother Barin got involved in increasingly daring but largely ineffective violent revolt. In May 1908 Barin played a role in the organization of a bomb attack on a horse carriage in which some British officials were presumed to be traveling. Unfortunately two British ladies occupied the coach and died in the bomb blast. Sri Aurobindo was arrested by the police under suspicion that he was behind this violent incident. He was put on trial for 'waging war against the King,' a charge that could have sent him to the gallows if convicted. This case sent shock waves all over India and across the British Empire. Sri Aurobindo's case was pleaded by a well-known Indian barrister C. R. Das. Lack of evidence of direct, active involvement in violent action finally led to his acquittal after one year, much to the discomfort of the British Viceroy, who by that time had come to the conclusion that Sri Aurobindo was "the most dangerous man in the British Empire." His incarceration had one major effect, which the British police could not have foreseen, or, for that matter, understood. Sri Aurobindo took his arrest and year-long incarceration as a God-imposed opportunity to concentrate fully on his inner, spiritual development, or *sādhana*. While in jail, he showed remarkably little concern about the court-case, but made an in-depth study of the *Bhagavad Gītā* and realized the presence of the personal Divine in everything and everybody around him.

By the time Sri Aurobindo was released from the jail the political scenario had very much changed. Almost all leaders of the Nationalist party were either in jail or in self-imposed exile. Everywhere there was depression and hopelessness, though the feelings against foreign rule were becoming stronger. Sri Aurobindo remained in Calcutta using his persuasive skills to unite the moderates and the extremists to a common agenda in order to give the freedom movement a realistic direction. He was now convinced that the political independence of India was only a matter of time, and that he had to concentrate on another important work, the inner growth of his countrymen. He started two journals – *Dharma* in Bengali and *Karmayogin* in English, both focused more on culture and yoga, less on politics.

Even after his release from jail, there was a realistic possibility that he might be rearrested. One evening when Sri Aurobindo was sitting with others in the office of *Karmayogin*, one friend burst in with the news that Sri Aurobindo was about to be arrested. Sri Aurobindo spent some time in Chandernagar before ultimately deciding to escape to Pondicherry, the capital of the French settlements

in India. With great secrecy and meticulous planning, on 1 April 1910 Sri Aurobindo boarded, under a false name, a steamer to Pondicherry.

Settling in Pondicherry

Sri Aurobindo expected initially to stay in Pondicherry for only a few months, or at most a year, to have time for his yoga meditation and inner growth, before reentering active political life. He was not inclined to meet anyone and did not want visitors to disturb his solitude. He was living on the upper floor of a rented house and would come down only to take his bath. A few youngsters who joined him from Kolkata were looking after the household.

Those early years of his stay in Pondicherry were difficult times. There was a perennial financial crisis; British spies kept a tab on all his visitors and activities. There was a warrant against him and there was apprehension that the French Government might deport him. Sri Aurobindo himself remained, however, completely unruffled, fully immersed in his meditation.

In Pondicherry Sri Aurobindo devoted most of his time to *sādhanā*. Though still interested in the large scale political and social developments that shook the world at that time, his concentration was on yoga. His principal study during the early years in Pondicherry was the *Rig Veda*, which he read, took notes on, analyzed, and translated into English. In contrast with his interests during his stay in Baroda, when he devoured works of Indian and European literature in large numbers, during this period his more conventional reading consisted largely of newspapers and a few Indian journals.

Once settled in Pondicherry, Sri Aurobindo decided to call his wife Mrinalini. She had been detained in Bengal by the British police and was staying in Kolkata with some family friend. However, before she could embark on her journey to Pondicherry Mrinalini suffered from some undiagnosed disease and died.

In 1914, a French couple, Paul Richard and his wife, Mirra Alfassa, visited Pondicherry and soon became acquainted with Sri Aurobindo. Paul Richard invited Sri Aurobindo to join him in bringing out a new journal named *Arya*. The objective of the journal in Sri Aurobindo's words was, "to feel out for the thought of the future, to help in shaping its foundations and to link it to the best and most vital thought of the past." By the time its first issue came out, the first World War started and soon after, the Richards had to return to France. This left the task of filling the 64 pages of the monthly journal to Sri Aurobindo, and he earnestly carried on with this responsibility for the next six years. He serialized many of his seminal writings in the pages of *Arya*. By the time he closed down the journal, he had completed almost all his major works including *The Life Divine*, *The Synthesis of Yoga*, *The Human Cycle*, *The Ideal of Human Unity*, *The Secret of the Veda*, *Hymns to the Mystic Fire*, *Essays on the Gita*, *Foundations of Indian Culture*, translations and commentaries on several major *Upaniṣads*, etc. Only a few of these texts, *Essays on the Gita*, *The Life Divine* and the first part of *The Synthesis of Yoga*, were revised and published in book form during his lifetime. Around 1915–1916 Sri Aurobindo started working on a poem, *Savitri*, that would become his most extensive literary creation.

Paul Richard and Mirra Alfassa returned to Pondicherry in 1920. Paul Richard went back to France but Mirra stayed and gradually took up an increasingly important role in the small community that began to form around Sri Aurobindo. Initially she was simply regarded as the most gifted of Sri Aurobindo's disciples, but over time, Sri Aurobindo, as he now came to be known, began to address her as 'the Mother,' in honor of her complete identification with the *śakti*, the Power which mediates between the Divine and the manifestation. In letters to his disciples, he often stressed that their consciousness and realization were essentially one, and that they differed only in their most outer roles and forms of manifestation.

On 24 November 1926 Sri Aurobindo had another major breakthrough in his own *sādhanā*. He had been patiently waiting and preparing for this event for years, but for others it was difficult to understand what actually happened on that day. At the time he only said "the power has descended into the subconscious." Almost ten years later he casually remarked that it had been "the descent of the Overmind into the physical." In Sri Aurobindo's terminology, the Overmind is the cosmic consciousness, way above the ordinary mind, from where, amongst several other things, all the major religions originate. According to the Vedic tradition there is a layer of consciousness still higher than the Overmind, which Sri Aurobindo called the Supermind. The exact nature of the Supermind is obviously difficult to grasp with ordinary human consciousness: Sri Aurobindo described it as more difficult for a person to comprehend than it would be for a monkey to understand the nature of abstract human thought!

The relative place of the Supermind in the Vedic hierarchy of different layers of conscious existence can however more easily be indicated. It is conceived as a link-layer between the upper hemisphere of *sachchidananda* (the unity of divine existence, consciousness, and bliss) and the lower hemisphere of matter, life, and mind. It is described as a world where there is already differentiation into form and function, but no diminution yet of the Divine omniscience and omnipotence. In other words, it is the only type of consciousness in which perfect harmony, knowledge, light, freedom, and immortality are in principle compatible with some form of individual existence. The Vedic Rishis knew about this type of consciousness, and strived to reach it, but considered it incompatible with life in the ordinary physical world. They described the Overmind, just below it, as a 'golden lid,' a layer so light and blissful that nobody could pass through it and return. Sri Aurobindo felt however that the time had come for the Supramental type of consciousness to become more accessible to humanity. He looked at it as the inevitable next step in the evolution of humanity. It is in this light that we have to look at the event that took place on 24 November 1926: for Sri Aurobindo, the "descent of the Overmind into the physical" was a necessary step in the larger project of making the Supramental consciousness a normal part of biological existence. He argued, in his main philosophical work, *The Life Divine*, that just as the human consciousness has come into being as the result of the gradual evolution of mind within other living material forms, the Supramental consciousness might get a natural biological embodiment as the result of a further evolution within humanity.

Self-Confinement

The immediate practical result of the events that took place on 24 November 1926 was that Sri Aurobindo retired entirely to a small, first floor apartment in order to concentrate fully on his inner work. From this time onwards, he left the daily care of the small community that had begun to develop around him, to the Mother, and this was the formal beginning of the 'Sri Aurobindo Ashram.' We know relatively little about what kind of inner work Sri Aurobindo did during the 24 years after his retirement to his rooms. He rarely spoke to anybody and entertained no visitors. Just before the Second World War he broke his leg and needed help for his daily chores. That was the only time when a few of his closest disciples had a chance to know about his daily activities. Otherwise he saw his disciples only 3–4 times a year in a silent 'darshan.' What we know of his inner life during this period is largely from his letters, from his poetry, and from the changes he introduced in some of his earlier writings. During the 1930s Sri Aurobindo answered a staggering number of letters to his disciples, of which over 5000 have been published. The published portion of Sri Aurobindo's correspondence runs to over 2000 pages. For several years, Sri Aurobindo would work till six in the morning to answer the letters he received. Most of them dealt with *sādhanā*, quite a few with literature, and a smaller number with other issues.

Around the same time he also took up the revision of a few of his major works like his *Essays on the Gita*, the first two parts of *The Synthesis of Yoga*, and *The Life Divine*. His poetic writings include sonnets, short poems, and metrical experiments as well as his most important written work, the epic poem *Savitri*. With its almost 24 000 lines and 724 pages, *Savitri* is in a class of its own. Its richness of imagery, beauty of expression, and sheer number of memorable lines could remind one of Shakespeare, but in terms of depth and width of spiritual experience it simply has no equal in the English language. It would not be surprising if posterity would count *Savitri* amongst the most valuable texts ever composed.

It may be noted that in spite of his official retirement from politics, Sri Aurobindo was one of the very few major public figures in India who recognized how serious the consequences of a victory of Nazi Germany and Japan would have been for the future development of human civilization. During the Second World War he gave his full support to the Allied war-effort. He publically supported Cripps' Mission which proposed a gradual transfer of power to Indians. One may wonder whether it was just a coincidence that the day India got its Independence from British rule happened to be Sri Aurobindo's 75th birthday.

Just before passing away in 1950, Sri Aurobindo wrote a few essays for a newly started Ashram journal, *Bulletin of Physical Education*, on the transitional period between our present state and the Supramental stage he envisaged for the future evolution of humanity. He also completed the revision of the first part of *The Synthesis of Yoga* and the whole of *Savitri*. He died on 5 December 1950. For 3–4 days Sri Aurobindo's body did not show any sign of decomposition. His body was finally laid to rest on 9 December 1950 in the courtyard just below his room. The Mother continued his work till her own

passing away in 1973 at the age of 95. The Ashram and the international township, Auroville, which she started in 1968, have continued to thrive as creative spiritual communities.

The Relation Between Yoga and Creativity

Sri Aurobindo was at the same time a yogi and an embodiment of the highest order of creativity. He took an *evolutionary* view of both reality and creativity, and looked at creativity in the context of the transformation of consciousness to higher and higher levels. Creativity is then not seen primarily as tied with productivity in the material sense, but as arising out of spiritual experience, out of purity in thought and action, out of the process of becoming fully liberated. The focus is neither on the creator nor on the product, but on the possibility of overcoming the limitations of one's individuality in order to achieve an increasingly direct, unmediated experience, and expression, of the truth-consciousness from which reality arises.

Sri Aurobindo lived his life in accordance with his own premises about the ascent of consciousness from normal human intelligence to higher levels of consciousness. For him consciousness is not only power of awareness, it is also dynamic and creative energy. As one moves from the ordinary, sensory mind-consciousness into the higher realms of consciousness, one becomes more and more illumined about the nature of reality. In this evolution of mind, the initial step is to elevate one's consciousness to a level where it comes in contact with that region of consciousness from which we occasionally receive insight, intuition, and holistic understanding. There the mind is no longer limited by sensory experiences and personal biases, but capable of seeing beyond fragmented and divisive appearances. As the mind gets more and more 'illumined,' it begins to work more through visions than thoughts, more through direct insight, intuition and inspiration than through 'constructed knowledge.' Ultimately, an illumined mind can get in touch with the spiritual source of inner illumination and creativity, and can then acquire knowledge directly, through intuition. Many of us have occasional moments of intuitive understanding, something which comes in a flash, the source and timing of which remains a mystery. According to Sri Aurobindo, intuition is a power of consciousness that can be developed systematically. It is when the consciousness of the subject comes into direct contact with the consciousness of the object that intuition can leap out like a spark or lightning. When human consciousness further ascends and unites with layers of consciousness closer to the spiritual origin of things and beings, then the sparks or flashes of intuition light up more and more purely till one can have a direct perception (without any mediation) of the truth behind manifest reality. At the highest levels of the evolution of consciousness intuition is not any longer a fleeting presence but stays as the primary source of knowledge. At the highest stage of consciousness, what Sri Aurobindo calls *supermind*, one is in a perpetual state of both cognitive and creative perfection, which at that level are one.

The conception of an evolution of consciousness was elaborated by Sri Aurobindo most extensively in his main philosophical work, *The Life Divine*. Sri Aurobindo starts by

pointing out that the gradual evolution of which Darwin had found his proofs in nature, is not just a matter of increasing complexity, but a progressive manifestation of ever-higher types of consciousness. Nature began its evolution from the seemingly unconscious state of inorganic matter to the half-conscious plant and animal life; then it gradually developed within certain mammals, the mental consciousness which we now see in humanity. Sri Aurobindo argues in *The Life Divine* that it appears *prima facie* unlikely that our present mental consciousness, with all its limitations, confusions, and obvious defects, would be the final end product of this huge, aeonic process of biological evolution. He proposed that there should be further steps in the evolution of consciousness, steps that ought to bring us closer to the consciousness, in which, according to the Vedic tradition, the entire manifestation has its origin. According to Sri Aurobindo, the next stage of this process should be a cosmic truth-consciousness in which the ego and the division between self and other will disappear. He holds that the evolutionary process will continue at least until there will be embodied individuals living in the perfect harmony of the divine consciousness of *Brahman*.

Sri Aurobindo constantly worked on the yogic technology of observation and transformation for the further evolution of himself and his disciples, which he took as samples or prototypes for the wider, collective evolution he saw taking place, more slowly, in humanity as a whole. For him yoga had the same relation to the inner nature and being of man as the natural sciences have to the forces of external nature like, say, steam or electricity. In another monumental work, *The Synthesis of Yoga*, he laid down the detailed processes through which one can successively progress and attain higher and higher states of consciousness. Authenticity and veridicality were the primary concerns of Sri Aurobindo in developing the methodology of this 'integral yoga.' This type of yoga can be considered scientific in the sense that it proceeds by experiments and that it bases all its findings on experience. The processes may as such still belong to the 'subjective' domain, but within that domain, they are rigorously investigated. As one moves further in inner exploration through yoga, many new capacities for knowledge, action and enjoyment are discovered. Inspiration, intuition, and creativity develop as products of these newly emerging capacities.

Substantial support for the validity of Sri Aurobindo's conception of creativity can be found in his own monumental writings, which comprise plays, poems, essays, commentaries and thousands of letters, and particularly in his pristine poetry, which epitomizes in *Savitri*. It is interesting to note in this context that Sri Aurobindo used *Savitri*, in his own words, as

a 'means of ascension.' He began with a passage on a certain mental level, and then, each time he reached a higher level, he rewrote that passage from the higher level. In fact, for many years, he did not regard *Savitri* as a poem to be written and finished, but as a field of experimentation, to see how far poetry could be written from the different levels of yogic consciousness, and how far each of these could be made creative. With each revision Sri Aurobindo tried to lift the level of the poem higher and higher toward what he called 'overmind poetry,' the mantric, revelatory utterances of that highest of the spiritual mind ranges. *Savitri* was published in its complete version only after he left his physical body.

Glossary

Creative achievement questionnaire A measure that gauges creativity using actual accomplishments that vary in the magnitude of creative achievements they represent. The scale includes visual arts (painting, sculpture), music, dance, individual sports (tennis, golf), team sports, architectural design, entrepreneurial ventures, creative writing, humor, inventions, scientific inquiry, theater and film, and culinary arts.

Criterion problem The methodological issue of what criterion provides a valid standard for identifying a person or product as creative. It is what is required when validating an instrument that purports to measure something associated with creativity.

MPAA ratings Evaluations of films by the Motion Picture Association of America: G (general admission), PG (parental

guidance advised), PG-13 (parents strongly cautioned because some material may be inappropriate for children under 13), R (Restricted, children under 17 would not be admitted without an accompanying parent or adult guardian), and NC-17 (no one 17 and under admitted).

Nobel prizes International awards currently bestowed in the categories of physics, chemistry, physiology or medicine, economics, literature, and peace.

Oscars (Academy Awards) Annual awards bestowed in the main categories of cinematic achievement by the Academy of Motion Picture Arts and Sciences.

Unit of analysis The specific nature of the cases that form the sample under investigation. In creativity research these are most often individuals, but the units can also be products.

Introduction

Various cultures and civilizations throughout history have used awards to honor those individuals who best represent highly valued achievements. Perhaps the most ubiquitous and conspicuous are the honors received for heroism in military combat. Examples include the French Croix de guerre, the German Eisernes Kreuz, and the US Medal of Honor. Nevertheless, some societies have also chosen to recognize accomplishments more often associated with peace rather than war. Perhaps the most salient examples are the gold, silver, and bronze medals bestowed on the top athletes every 4 years at the Olympic games. Also in this second category are various ways of recognizing major creative accomplishments. The ancient Greeks allotted annual awards to the best plays shown in the Athenian Theater of Dionysius. Multiple winners of these dramatic competitions include the great tragedians Aeschylus, Sophocles, and Euripides.

In modern times the best known awards of this kind are probably the Nobel prizes for literature and the sciences, the latter category encompassing separate honors for physics, chemistry, physiology or medicine, peace and, most recently, economics. The Nobels are international awards, but many countries feature more regional awards. Thus, the United States has Pulitzer Prizes for newspaper journalism (e.g., international reporting, feature writing, commentary, criticism, editorial cartooning, and feature photography), literary achievements (in fiction, drama, history, biography or autobiography, poetry, and general nonfiction), and musical composition. Many other awards recognize specific domains of creativity. For example, the Miguel de Cervantes Prize is awarded to the most outstanding writer in the Spanish language (but not necessarily a Spanish writer). Of a similar nature are the Goethe (German) and Camões (Portuguese) prizes. Most well-established professions

will support an appropriate set of honors. For instance, research psychologists can receive the Award for Distinguished Scientific Contributions granted by the American Psychological Association.

The most prestigious awards are often bestowed upon creators in impressive gala events. Perhaps the most prominent example are the Oscars given out by Hollywood's Academy of Motion Picture Arts and Sciences in a ceremony broadcast worldwide. Moreover, the recipient might receive the honor directly from the hands of a major celebrity, including royalty. Nobel laureates receive their gold medals directly from the Swedish monarch. At the other extreme, far less eminent honors might be simply announced in some press release or official newsletter.

The first psychologist to use awards to study creativity was Francis Galton in his 1874 *English Men of Science: Their Nature and Nurture*. Galton wanted to study the development factors underlying exceptional scientific achievement so he distributed questionnaires to scientists of sufficient distinction that they had been elected Fellow of the Royal Society of London. Because fellows can only be elected by previous fellows, this group formed a highly elite sample. Among the more than 100 scientists responding to his questionnaire were the mathematician Arthur Cayley, the physicist James Clerk Maxwell, the biologists Charles Darwin and T. H. Huxley, and the evolutionary philosopher Herbert Spencer. Using their responses, Galton was able to show how family background (e.g., birth order) and educational experiences (e.g., dislike for school) can affect the emergence of scientific creativity.

From time to time other researchers have followed in Galton's footsteps, Nobel laureates and Oscar winners perhaps receiving more empirical attention than any other group of awardees. To appreciate why investigators have examined awards let us first examine the distinct advantages of this

approach. Next we shall review some of the actual applications of awards to the study of creativity. In addition, the use of awards can be compared with closely related indicators of creativity. But an encyclopedia entry such as this would not be complete without discussing potential disadvantages as well.

Advantages

Among the oldest issues in the study of creativity is the 'criterion problem.' By what standard do we determine that a person or product is creative? For example, suppose the investigator wanted to study the personality correlates of creative achievement among US psychologists. One plausible solution might be to use awards and honors as an index of creative achievement in psychology. Such recognition might include election to the National Academy of Sciences (NAS) or receipt of the Distinguished Scientific Contribution Award (DSCA) of the American Psychological Association. Such honors would seem to have a *prima facie* claim to validity. After all, expert peers are almost invariably involved in deciding who receives the honors. Moreover, the recipients must normally undergo a rigorous nomination and evaluation process in which a candidate's career is assessed with the aid of supporting documentation, often including nomination letters and complete curriculum vitae. It is reasonable to assume that those who have such honors bestowed upon them are more creative than those who do not.

As a consequence, awards and honors provide a potential solution to the criterion problem. Furthermore, such formal acts of recognition have two other assets as criteria variables.

First, they can be used to assess the magnitude of creativity. In many domains of creative achievement, awards and honors can be arrayed in a hierarchy from the most competitive to the least competitive. In psychology, for example, NAS membership is more selective than getting the DSCA. Furthermore, below the latter are the various career achievement awards offered by the many APA divisions, such as the Ernest R. Hilgard Award for a Career Contribution to General Psychology bestowed by the Society for General Psychology (Division 1). Below that award might be one of the more specialized divisional awards, such as the George A. Miller Award for an Outstanding Recent Article in General Psychology (also Division 1). Lower still would be election as Fellow of APA or the Association for Psychological Science (APS). Needless to say, election to NAS does not have to represent the acme of this scale. A true elite has earned a Nobel Prize in either economics or physiology/medicine. Accordingly, we might array the award hierarchy as follows: Nobel, NAS, DSCA, APA divisional career awards, APA divisional 'best' publication awards, and APA or APS Fellow status. Hence, award criteria do not have to represent dichotomous either-or measures. Instead, it is sometimes possible to define a rank-category scale.

Second, award criteria measures can be applied to different units of analysis. Some honors are routinely assigned to individual creators, whereas others are allotted to single creative products. Indeed, that contrast was already implied in the preceding paragraph. The Hilgard Award recognizes a lifetime of distinguished contributions, whereas the Miller Award honors a single notable contribution. The distinctions can be made even finer. On the one hand, many professional organizations

offer 'early career' awards as well as lifetime career awards. For example, APA's Division of Developmental Psychology annually bestows the Boyd McCandless Award to young promising researchers and the G. Stanley Hall Award to those who are entering the final phase of their careers. On the other hand, some organizations may distinguish between types of creative products to be honored. Besides the Miller, APA's Division 1 also bestows the William James Book Award. Interestingly, these distinctions may be combined to yield an honor like Division 1's Gardner Lindzey Dissertation Award – a kind of integrated early career and best product award.

Researchers tend to use award criteria in two different ways. The first is to introduce a specific award or honor as a sampling criterion. This is what Galton did in *English Men of Science*. Only scientists who were Fellows of the Royal Academy were sent questionnaires. The second usage is to sample individuals with and without the award and then define a dichotomous variable that equals 1 if a person received the honor and equals 0 if they did not. As an example, a number of investigators have compared US scientists elected to NAS to those who failed to earn that distinction.

Illustrations

To appreciate fully the value of using awards in creativity research, extended examples are necessary. Consequently, below are overviews of two rather extensive research literatures. The first concerns scientific creativity and uses the individual creator as the unit of analysis. The second concerns artistic creativity and uses the single creative product as the analytical unit. The specific topics are Nobel laureates and award-winning movies, respectively.

Nobel Prizes

Alfred Nobel was the inventor of dynamite and a major Swedish armaments manufacturer. Having read a premature obituary that condemned him as the "merchant of death," and having never married and fathered a family, he decided to use his vast wealth to leave a more positive legacy after his death, which took place about 8 years later. In his last will and testament, written about a year before his death, Nobel left a huge amount of money to award contributions to physics, chemistry, physiology or medicine, literature, and peace. The first such awards were bestowed in 1901. A prize for economics was instituted in 1968 and first awarded a year later. Because this award was not part of Nobel's original will, some observers contest that it does not count as a true Nobel. Nonetheless, the selection procedures for the economics prize are every bit as rigorous as the procedures for the prizes. Both nomination and selection must meet extremely high standards. For instance, the physics, chemistry, and economics prizes are chosen by five-member committees appointed by the Royal Swedish Academy of Sciences. Nominators are also carefully restricted. It often takes a considerable time for someone eligible for the Nobel to finally receive the honor. For example, Einstein received the prize for physics in 1921. The prize citation specified his work on the photoelectric effect, a contribution he made in 1905. Some potential recipients have even died before they could be appropriately honored.

Some empirical investigators have been content to study the general characteristics of Nobel laureates, often concentrating on some subgroup, such as the scientists or the writers. Although these inquiries can often yield fascinating insights into the constitution of the typical laureate, their value is diminished whenever they lack a suitable comparison group. As a result, the most useful empirical studies will introduce some type of between-group contrasts. These contrasts largely assume two forms: (a) laureates in one domain are compared to laureates in another domain and (b) laureates are compared to nonlaureates.

Laureates versus other laureates

Researchers have often scrutinized whether a Nobel recipient in one category differs from a recipient in another category. Some of this work has concentrated on early developmental experiences. For instance, in comparison to laureates in literature, laureates in the physical sciences are far more likely to have fathers who were academic professionals. Additionally, laureates in literature were far more prone to have lost their father during their minority years in comparison to laureates in the physical sciences.

Other researchers have examined the differential career trajectories of laureates in the various categories. In general, physicists reach their career peak earlier than chemists, who in turn tend to peak earlier than researchers in physiology or medicine. These differences show up in the ages at which the scientists are most likely to receive their highest honor. Physicists are around 49 years old, chemists about 52, and biomedical researchers approximately 55. Nobels in economics are bestowed to even older recipients.

The foregoing results imply that the specific nature of creativity varies across the Nobel categories. Creativity in physics has a different composition than in, say, literature.

Laureates versus non-laureates

Just as interesting are studies that compare Nobel laureates with nonlaureates in comparable disciplines. These investigations have found the following differences: (a) laureates are more likely to have attended prestigious universities and to have studied under previous laureates; (b) despite a strong commitment to their chosen area of research, laureates are much more likely to have many interests and hobbies; (c) laureates implement cognitive processes that are identifiably different from comparison groups; (d) laureates are more prolific, producing many more publications per year than their less illustrious colleagues; and (e) in comparison to nonlaureates, Nobel prize winners move up the academic ladder much more quickly, attaining full professorship at a younger age. These contrasts often hold up even when Nobel laureates are compared to members of the National Academy of Sciences, themselves a distinctive group of scientists. When the comparison group consists of even less distinguished scientists, the contrasts most often become even more dramatic.

It should be noted that far more research is devoted to laureates in the sciences than in literature or peace. Awards in the latter two categories are often viewed as more influenced by political concerns whereas the science awards are seen as more objective. The specific achievements in the non-science awards are also more heterogeneous and controversial. The sciences

have the advantage that a much stronger consensus exists on what counts as a substantial contribution to a given domain.

Movie Awards

Nobel's original intention was that the prize recognize specific achievements within 1 year after their occurrence. At first the prize committee tried to carry out this wish. It was for this reason that Dmitri Mendeleev was denied the prize for chemistry: His famous periodic table of the elements was already too old at the beginning of the twentieth century. Nevertheless, the committee soon realized that this restriction was impractical. Time is necessary to obtain sufficient perspective on the magnitude of an achievement. Accordingly, the award is often bestowed long after the original contribution that inspired the honor. Because of the delay, the Nobel often functions as a career achievement award. When Einstein received the Nobel in 1921, the citation said that he was so honored "for his services to Theoretical Physics, and especially for his discovery of the law of the photoelectric effect." The prize committee knew that Einstein was already better known for his special and general theories of relativity. Sadly, by the time the prize committees began to prolong the period in which eligible accomplishments would be considered, it was already too late for Mendeleev, who died in 1907.

It is interesting, therefore, that awards in the arts often insist on a 1-year time window. That is, each award ceremony recognizes the greatest contributions in a given year. Thus, in the United States, the Pulitzer Awards clearly concentrate on the most recent achievements in its various categories. The same time limitation holds for the National Book Awards, all entries having to be published between December 1 and November 30 of the following year. This temporal focus is especially conspicuous for honors in theater and film, which are invariably confined to productions that appeared in a single year interval. Of the film honors, probably the famous are the Oscars awarded by the American Academy for Motion Picture Arts and Sciences in Hollywood. But these are far from the only film honors. The Internet Movie Database lists over 1500 award ceremonies, albeit the largest number of these represent local film festivals. The number of high-prestige movie awards is much smaller, and so the bulk of the empirical studies have concentrated on the Oscars alone. That will be the emphasis here as well.

Award categories

As will be apparent to anyone who has watched a televised Oscar ceremony, awards are offered in numerous categories of cinematic achievement. The biggest honor is that given for best picture, followed by best director, screenwriter (both original and adapted script), the four acting awards – male and female leads and male and female supporting. Less conspicuous, but no less important, are the honors given for cinematography, editing, art direction, costume design, makeup, score, song, and ending with the more technical contributions of visual effects, sound effects editing, and sound mixing. Admittedly, not all award ceremonies offer honors in all of these categories. Indeed, some will stick to only the first half dozen or so. Furthermore, some organizations will split one or more categories into more specialized achievements. The Golden

Globes of the Hollywood Foreign Press Association give separate best picture and lead acting awards for dramas and comedies or musicals. Finally, it should be observed that most organizations bestow two levels of honors – the nomination and the outright award. Given the competitiveness of these honors, receiving an “Oscar nod” is deemed no mean achievement, even if it is not followed by an Oscar statuette.

Empirical research concerning these diverse awards leads to two major conclusions; first, the awards and nominations bestowed by major organizations display a very conspicuous consensus for most award categories. This agreement holds independent of whether the honors are decided by professionals, journalists, scholars, or critics. The consensus is probably surprising given that some organizations presume that their assessments are truly distinct. For instance, the New York Film Critics Circle Awards were initiated as an anecdote to the Oscars, which the East Coast critics thought were contaminated by studio politics and local tastes.

Second, although the inventory of award categories is quite large, certain honors tend to go together. In particular, if we leave aside the best picture award as representing a global honor, then all of the remaining nominations and awards have been shown to form the following four creative clusters: (a) dramatic – consisting of directing, writing, editing, and acting; (b) visual – cinematography, art direction, costume, and makeup; (c) technical – visual special effects, sound effects editing, and sound mixing; and (d) musical – score and song. Notably, these four clusters do not all correlate in the same way with a film earning the best picture award: the most prominent correlation is for the dramatic cluster, followed by the visual cluster, with only one tenth the effect. The technical and musical clusters, in contrast, are not associated with best picture honors. In other words, great cinema seems to require pretty much the same aesthetic assets as great theater, namely, drama and visuals. Special effects and music are optional.

Award correlates

It is instructive to examine how the movie awards correlate with other aspects of the cinematic product. Such correlations can provide an overall idea of how creativity operates in filmmaking. Below is a summary of the results from a series of studies that looked at films that received at least one nomination for an award from a major organization:

1. *Dramatic cluster*: Films that earn numerous awards and nominations for directing, writing, acting, and editing (a) are more likely to be adaptations of a nonfiction work, to be a true story or biopic, to be a drama or romance, to have a long running time, to receive an R rating from the Motion Picture Association of America (MPAA), to receive critical acclaim, and to earn a reasonably good box office, but (b) are less likely to be sequels or remakes or to receive an MPAA rating of G or PG-13. In short, such films appear to represent more serious, art-oriented cinematic products.
2. *Visual cluster*: Films that earn numerous awards and nominations for art direction, writing, acting, and editing (a) are more likely to have big budgets, to have a long running time, to be adaptations from novels or nonfiction works (especially one of the ‘classics’), to be a true story or biopic, to be a romance or musical, to receive an MPAA rating of

PG, and to earn reasonable box office, but (b) are less likely to be comedies or to earn an MPAA rating of R. In other words, these films seem more aligned to the more show-business traditional Hollywood entertainment.

3. *Technical cluster*: Films that earn numerous awards and nominations for visual effects, sound effects editing, and sound mixing (a) are more likely to have big budgets, to be sequels, to have long running times, to get an MPAA rating of PG-13, and to earn excellent box office, but (b) are less likely to be dramas or comedies, to be adaptations from plays, to have the original author write the adaptation, or to receive an MPAA rating of R. Such films are also entertainment oriented, but with an emphasis on action, adventure, and thrills – the kind of motion picture that attracts lots of teenagers to the movie theaters.
3. *Musical cluster*: Films that earn numerous awards and nominations for score and song (a) are more likely to have big budgets, to have long running times, to be romances or musicals, and to receive an MPAA rating of G or PG, but (b) are less likely to be a comedy, to be an adaptation from a play, or to get an MPAA rating of R. Here the primary function of the film is to provide a vehicle for the music.

Two observations about the foregoing should be offered. First, the only film attribute to correlate positively with all four creative clusters is running time. Longer films have more opportunity to earn a nomination or award in a major category of cinematic achievement. Second, if the goal is to earn critical acclaim, a film-maker should focus on winning honors in the dramatic cluster, but if it the goal is to do an excellent box office, the focus should be on accomplishments in the technical cluster. Put differently, the creative clusters differentiate between film as art and film as business.

Disadvantages

Although award measures have proven useful in research on creative persons and products, such assessments are not without problems. One drawback is that they are clearly confined to the highest levels of creativity – what researchers often style “Big C” Creativity. Everyday “little-c” creativity does not receive conspicuous recognition. At best, such creativity might earn some localized praise, such as someone getting ‘employee of the month’ for a particularly imaginative and useful recommendation placed in the company ‘suggestion box.’ Moreover, even in the population of exceptional creators, certain honors have rather low base rates. At present, a little over 100 writers have received the Nobel Prize for Literature since its inception. When one considers that these writers represent every major literary language and hail from every continent except Antarctica, it is clear that the vast majority of highly creative writers will never receive this award. Although many of these writers will be recognized by more regional awards – such as the Cervantes, Goethe, and Camões prizes – it remains the case that award winners form an elite at the uppermost tail of the creativity distribution.

Even worse, the history of any award will be embarrassed by a certain number of false positives and false negatives. The former represent cases where someone received the honor

even when he or she was undeserving. This was a principal reason why the Nobel prize committees now ignore Nobel's stipulation that the awards go to recent contributions. Even then, the awards sometimes go to the wrong recipients. When it was initially announced that the 1923 Prize in Medicine would go to Frederick Banting and John Macleod for the discovery of insulin, Banting protested that it was Charles Best rather than Macleod with whom he should share the honor. Banting almost refused the award, and when he finally consented, he shared half of his prize money with Best. According to Banting, Macleod's sole contribution was to provide some laboratory space for the experiments that Banting and Best conducted. False positives also happen in the case of awards for creative products. Film critics and historians are fond of pointing out the best picture Oscars that went to the wrong film in a given year. In 1953 Cecil B. DeMille received the best picture award for *The Greatest Show on Earth* when the other four nominees were *High Noon*, *Ivanhoe*, *Moulin Rouge*, and *The Quiet Man*. All but *Ivanhoe* are now considered much better films.

False negatives occur when a deserving person or product fails to receive the appropriate recognition. The history of the Nobels contains many examples of great creators who never received the honor. The literary prize, especially, has snubbed many notables. The false negatives include W. H. Auden, Jorge Luis Borges, Karel Čapek, Henrik Ibsen, James Joyce, Franz Kafka, André Malraux, Vladimir Nabokov, Marcel Proust, Leo Tolstoy, Mark Twain, and Émile Zola. In the early years great writers were often overlooked because of an excessively restrictive application of Nobel's will (which might be taken to imply that the work should be idealistic), but later literary creators were often passed over for political reasons. Also, political factors have probably introduced some false positives among the literature laureates.

With respect to the science Nobels, many false negatives ensue from the requirement that the award not go to more than three persons in a given year. Notwithstanding this provision, some awarded achievements should have been credited to four or more scientists. A case in point is the 1965 Nobel Prize for Physics that was bestowed on Richard P. Feynman, Julian S. Schwinger, and Sin-Itiro Tomonaga for their work on quantum electrodynamics. This left out Freeman C. Dyson, who had made the important contribution of showing that their independent formulations were actually equivalent.

False negatives are particularly likely when an achievement has a narrow time window for eligibility. Because Oscars are only given to cinematic achievements in a single year, the Academy cannot carry over an achievement to the next year if there are too many deserving nominees in a given year. Richard Burton was nominated seven times for a best acting Oscar (six lead and one supporting), but never received the honor before his death. Peter O'Toole has been nominated eight times, most recently in 2007, but has so far only received an Honorary Award not associated with a specific cinematic achievement.

Ironically, the existence of false negatives can sometimes produce false positives. If someone in the film industry has repeatedly received an Oscar nod without any ultimate success – always a bridesmaid never the bride phenomenon – then a “sympathy vote” may emerge that will award a person for an accomplishment that does not represent his or her best work.

Martin Scorsese was unsuccessfully nominated for best director five times before receiving it on his sixth nomination, in the latter case for a lesser directing achievement and against some rather stiff competition. The last illustration shows that awards can often be subjected to various contaminating influences that can partly undermine their validity. To offer another example from the realm of film, a picture nominated for a best picture Oscar will improve the chances of awards for those involved in making the film, particularly the high-profile directors and actors. An even more striking example is seen in those international piano competitions where the order of each pianist's performance is determined by chance. Those who perform first are at a disadvantage relative to those who perform later. In this case, success is literally a matter of the luck of the draw.

Apart from the above problems, award indicators often have limited applicability. Not every domain offers suitable awards, or at least comparable awards. The divisional awards offered by the American Psychological Association provide a good example. There are more than 50 divisions, most (but not all) offering one or more awards. Yet there is no consistency in the number and type of awards. Naturally, some of this inconsistency can be ascribed to the fact that some divisions emphasize pure research whereas others emphasize practice or application. Yet even among the research-oriented divisions, there is no consensus on what achievements to include in the award programs. The division for developmental psychology has an early career award, whereas the personality and social psychology division does not. The experimental psychology division has an early investigator award, but the winning publication has to appear in the *Journal of Experimental Psychology*. Some divisions have dissertation awards, and others do not. And so forth. This means that it would be next to impossible to use division awards to assess creative achievement in American psychology. Whether or not a given psychologist won an award would partly depend on his or her subdiscipline.

Comparisons

Given the measurement problems that can confront application of award measures, one should consider the use of alternative but comparable measures. At the very least, these alternatives can be used to crosscheck the award assessments. In any case, the alternatives differ depending on whether the unit of analysis is the product or the person.

Creative Products

The optimal manner to assess the differential creativity of separate products is often contingent on the domain of creative achievement. In the case of the sciences, many studies rely on the number of citations a given publication receives in the professional literature. Such citation counts have the advantage in that they are less selective. It is less demanding to publish an article or book that is cited by others in the field than to have the publication win a major award. Furthermore, because award-winning work is not necessarily highly cited, citation counts can provide an independent assessment of a product's impact.

In the arts, citations are less meaningful as indicators of quality, and so alternative measures are necessary. For example,

the creativity of musical compositions can be gauged by the frequency of performance or recording. This approach has been used to evaluate the differential aesthetic success of plays as well. In the case of poetry, an indicator might consist of the number of times a particular poem is included in various anthologies or how often lines from that poem appear in compilations of great quotations.

There is one assessment technique applicable to both artistic and scientific products: expert evaluations. Obvious examples are the judgments of professional critics. As noted earlier, the evaluations of film critics have been shown to correlate with nominations and awards received in the dramatic cluster. Critical evaluations are available for many other art products, including theater, fiction, music, and even video games. In a slightly different form, the same approach can work for scientific products. In this application, experts are asked to evaluate journal articles or monographs. For example, some journals have their own 'best article' awards in which members of the editorial board are asked to evaluate various nominees. Curiously, one investigation showed that the articles so honored did not exhibit higher citation rates than those not so honored. It is likely that judges require a longer time perspective than just focusing on the publications that appeared in the most recent annual volume.

Creative Persons

If the goal is to assess persons rather than products, then some of the preceding approaches can be carried over with only minor modifications. Certainly expert evaluations can just as well be applied to individuals. In fact, such assessments were introduced early in the twentieth century by James McKen Cattell. Most commonly numerous experts in a particular domain are asked to identify the top contributors to the field. These survey results are then consolidated into a single ranking or rating. In the sciences, citation counts can be implemented, only in this case the citations involve a creator's total output rather than a single publication.

Two other measurement strategies are unique to individuals; first, creativity can be assessed in terms of productivity, especially total lifetime output. Of course, the specifics of what is counted depend on the domain creative achievement: patents for inventors, journal articles for scientists, films for directors, etc. If the creative domain entails a diversity of products that cannot all be treated equally, then some kind of weighting scheme is applied. For example, in assessing the productivity of composers, more weight must be assigned to a symphony than to a song. Finally, if the creators under investigation are still alive, then some adjustment must be introduced for age. On the average, older creators will have accumulated more output than younger creators.

Second, creativity can be gauged according to eminence. Typically, this might entail a measure of the amount of space devoted to each creator in standard reference works, such as encyclopedias and biographical dictionaries. To maximize reliability, these space measures should use as many sources as possible. In addition, it is often necessary to implement corrections for certain biases that sometimes intrude on such measures. For instance, reference works often devote more space to literary figures and to visual artists. Research has shown that

the differential eminence of creators tends to be relatively stable over time, even across centuries. The most famous painters in the Italian Renaissance remain famous today.

Citation, productivity, and eminence measures invariably exhibit highly skewed distributions with a long upper tail. Award-winning creators are most likely to be found among the individuals in that tail. In fact, citation counts have even been used to predict recipients of a Nobel Prize. Unlike award measures, however, citation, productivity, and eminence measures can discriminate creators at the lower end of the distribution – the individuals who will never earn any major awards.

Integration

Major awards and prizes can provide widely accepted evidence of the highest-level creative achievement. Although the most celebrated awards have very low base rates, these can be combined with lesser honors to create an ordinal scale. Better yet, this scale of acclaim can be integrated with continuous measures, such as eminence and productivity, to generate a composite indicator that covers the full range of what has been called 'Big-C Creativity.' Indeed, it is even possible to extend the measurement down to the lower reaches of 'little-c' or more everyday creativity. This possibility is partially realized in the 2005 Creative Achievement Questionnaire (CAQ). Respondents are first asked to identify the areas in which they have somewhat more "talent, ability, or training than the average person." The specific domains are visual arts (painting, sculpture), music, dance, individual sports (tennis, golf), team sports, architectural design, entrepreneurial ventures, creative writing, humor, inventions, scientific inquiry, theater and film, and culinary arts. Then for each of these areas the respondents address a series of questions that define an 8-point scale, with 0 indicating the absence of any talent. Beyond this zero point are inquiries about low-level creativity, such as taking music lessons or having performed in a play. Higher up come more demanding criteria, including publication, shows, grants, critical reviews, citations, and special prizes. Although the awards are designated as local or national, it would certainly be possible to add a higher point on the scale to allow for the receipt of international awards, such as a Nobel or an Oscar. Such an extended version of CAQ would then span the complete spectrum of domain-specific creativity, from none whatsoever to the highest imaginable.

It is hoped that someday awards will be incorporated into such an inclusive measure of creative achievement. CAQ scores have been shown to correlate positively with alternative indicators of creativity, such as divergent thinking and creative personality. Such scores also correlate with other dispositional traits that are independently correlated with creativity, such as openness to experience and defocused attention. Therefore, high-prestige awards can be used to discern whether these same correlates help account for some fortunate creators managing to receive the highest levels of recognition. To illustrate, does a Nobel laureate differ from a Fellow of the National Academy or Royal Society in the same way that the latter differ from a scientist who received lesser honors? It is conceivable

that a single psychological continuum connects the lowest levels of creativity with those that are the most universally acclaimed.

Barriers to Creativity and Creative Attitudes

G A Davis, University of Wisconsin, Madison, WI, USA

This article is reproduced from the previous edition, volume 1, pp. 165–175, © 1999, Elsevier Inc.

Glossary

Creative attitudes Dispositions, temperaments, or orientations that influence one's way of feeling or acting in relation to creativity.

Creativity consciousness Awareness and appreciation for creativity, creative innovations, and creative people.

Cultural barriers Conformity pressures rooted in social influence, expectations, and social or institutional norms.

Emotional barriers Aspects of personality or 'emotional upset' that interfere with creative thinking; they may result from temporary problems (e.g., anger, fear, or hate) or more permanent sources of insecurity (e.g., anxiety, fear of failure, fear of criticism or rejection, or poor self-esteem).

Perceptual barriers Habitual ways of seeing and comprehending that make it difficult to see new meanings, relationships, and ideas; perceptual set, mental set, or functional fixity.

Personality Distinctive individual qualities of a person, such as attitudes and ways of reacting, that reflect the person's essential character.

Self-actualized creativity A general form of creativeness, a lifestyle; it includes mental health and growth toward self-realization.

Special talent creativity High, perhaps recognized, creative productivity in a special area; it may or may not include mental health.

The present discussion of barriers to creativity and attitudes that promote creativity is based on a broad conception of creativity. As illustrated on the horizontal axis of [Figure 1](#), a person may be low to high in general creativeness. One high in this trait takes a creative approach to most aspects of life. It is a way of living, growing, and perceiving one's world, as well as a way of thinking and solving problems. Such a person is mentally healthy and self-accepting, and grows toward self-realization. In the 1950s Abraham Maslow called this *self-actualized creativity*. As represented on the vertical axis of [Figure 1](#), a person may also be low to high in recognized creative productivity, or what Maslow called *special-talent creativity*. By definition, a person high in this dimension has achieved recognition for socially judged creative achievement, for example, in art, science, or business. They may or may not be mentally healthy in the self-actualization sense. The reason for noting this distinction, which acknowledges both a general creativeness and creative accomplishment in specific areas, is that several influential writers have argued recently that the word *creative* applies only when one's peers (or society) have judged one's work to be 'creative.' Further, the work must permanently alter the particular field. Such a definition restricts the word *creative* to only those who have achieved creative *eminence*, for example, Sigmund Freud, Pablo Picasso, T. S. Eliot, or Martha Graham. By exclusion, the remaining 99% of everyone would be *not creative*. Vincent van Gogh, for example, would have been judged uncreative until later art critics agreed that his paintings were creative.

For present purposes, a restrictive definition is inappropriate. The current more general and accepted definition acknowledges the obvious – that many, many people think and act creatively, some in just a few areas and some in all areas of their lives, and some achieve at least limited recognition. The broader definition also acknowledges the truism that everyone has an opportunity to live a more creative life and become a more fulfilled, creatively productive person.

Barriers to Creativity

The following five categories of barriers – learning and habit, rules and traditions, perceptual barriers, cultural barriers, and emotional barriers – will help distinguish blocks to creativity in different but overlapping categories. Some scholars argue that everyone is born creative, but early years of social pressures at home, at school, and in the community destroy lively imaginations and promote conformity.

Learning and Habit

The most obvious barrier to creative thinking and innovation simply is habit – our well-learned ways of thinking and responding. It begins early. We learn 'correct' responses, routines, and patterns of behavior. We learn language habits and conceptual

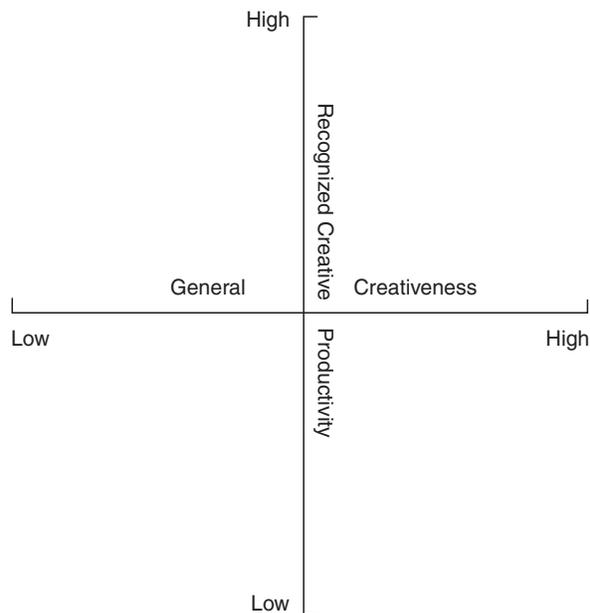

Figure 1 Two-dimensional illustration of personal creativity. A person may be low to high in general creativeness, which is a lifestyle and a thinking style (Maslow's self-actualized creativity), and low to high in recognized creative achievement (Maslow's special-talent creativity).

categories. We learn "the way things have always been done" and "the way things are supposed to be done." Over the years it becomes difficult to see and create new possibilities – to break away from or suppress our creativity-squelching habits.

When did you last try something truly new? An exotic restaurant? A new sport? A college course in an intriguing topic? Do old habits and expectations interfere with new ideas, activities, and possibilities? Consider this puzzle: Remove six letters from ASIPXPLETLTERES. What word is left? (Answer at end of article.) The ability to form habits and expectations is, of course, a necessary capability for humankind, one that directs our daily behavior. However, learning and habit are both a blessing and a curse.

Rules and Traditions

As with learning and habit, social groups – from one's family to educational, corporate, national, and international groups – could not function without the rules, regulations, policies, and traditions that guide personal, social, and institutional conduct. However, 'guide' often means restrict, inhibit, or prohibit. As an example of restrictive rules and traditions, in a 1995 article Don Ambrose criticized the inflexibility of school systems and other traditional organizations. He listed these traits of "dullard, brain-damaged bureaucracies inherited from the old industrial era": myopic and coercive leadership that treats employees as automatons; premature judgment; repressed creativity; anger, frustration, and resentment; inflexible conformity; reflexive ritual; inflexible attitudes; and being habit-bound. Ambrose claimed that the absence of creative flexibility was due to top-heavy bureaucratic structures that

put people into highly specialized roles, limiting employees' concerns to well-defined departmental work at a cost of large-scale visionary thought. Such employees have little reason to take risks beyond the confines of established procedures, particularly since mistakes are routinely punished.

In contrast, suggested Ambrose, "creatively intelligent post-industrial organizations" can improve creative thinking with visionary leadership; critical analysis and judgment; creative thinkers and creative teamwork; excitement, pride, and purpose; and flexibility, sensitivity, responsiveness, and dynamism. The issue is one of attitudes. A person can be inflexibly tied to rules, or can be creativity conscious – open, receptive, and encouraging of new ideas.

Van Gundy also described organizational barriers to creative innovation that are based in rules and traditions. One barrier is the status hierarchy. Lower-status persons are reluctant to suggest ideas to those in higher positions due to insecurity and fear of evaluation. If lower-status persons are routinely excluded from decision-making meetings, it is even less likely that their creative ideas will 'trickle up.' Also, if a new idea threatens to reduce status differences – such as giving every sales representative the title of 'vice president' – the idea is certain to be resisted by persons at higher levels, such as current vice presidents.

The formalization barrier refers to the degree to which following rules and procedures is enforced. If organization members are clearly expected to behave in prescribed ways, and innovation is not prescribed, few new ideas and proposals will appear. On the positive side, when an innovation is accepted, an efficient formal structure will expedite its implementation.

Procedural barriers include policies, procedures, and regulations (including unwritten ones) that slow or prevent creative innovation. Some examples include promoting administrators based on analytic skill, not on their creativity or ability to develop a creative atmosphere, and insisting on the slow, orderly advancement of an innovation early in its development, with excessive creativity-restricting control. Rules and traditions keep the system working. However, like habit, such predetermined guides tend not to promote creativity.

Perceptual Barriers

From a lifetime of learning we are accustomed to perceiving things in familiar ways, often making it difficult to see new meanings, relationships, and ideas. Psychologists refer to our predisposition to perceive things in certain ways as a perceptual set, a mental set, or functional fixedness. It is the reverse of flexible, innovative thinking. Perceptual sets are different for different people, rooted in our unique experiences, interests, biases, and values. Perceptual sets are tied to our tendency to make quick decisions and jump to conclusions, rather than flexibly see alternatives.

Perceptual barriers make us 'kick ourselves' for not seeing a solution sooner. One classic demonstration showed that when a piece of string was needed to solve a problem, the string would quickly be perceived and used if it were dangling from a nail on the wall, but not if it were hanging a 'No Smoking' sign, a mirror, or a calendar. Perceptual blocks also prevent us

from getting a complete and accurate picture of our world; the 'real problem' or 'truth' may be missed. For example, based on symptoms that seem familiar, a physician, auto mechanic, or computer expert may persist in misclassifying a problem and will recommend incorrect treatments. A school teacher who fixates on IQ scores will fail to perceive students who are highly creative, highly artistic, or gifted in a single area such as theater studies or computer programming. An instructor who successfully uses a particular teaching method for many years will not recognize another technique as being even more effective. Old habits interfere with new perceptions.

One creativity recommendation, "make the familiar strange," encourages us to see common objects and situations in new ways, to overcome too-familiar perceptual features, and to look for new and different ideas and perceptions. Much creativity involves a mental transformation – the perception of new meanings, combinations, and relationships that depend upon overcoming perceptual barriers.

Cultural Barriers

Cultural barriers amount to social influence, expectations, and conformity pressures which are based on social and institutional norms. Cultural blocks include habit and learning, rules and traditions, and more. They include conforming to the ways we think others expect us to behave and a fear of being different. The result is a loss of individuality and creativity.

Creativity leader Paul Torrance documented three developmental drops in creativity test scores. The first occurs when children enter kindergarten, an early time when conformity and regimentation suddenly become the rule. A larger decrease occurs in fourth grade, Torrance's infamous 'fourth-grade slump.' Both drops in creativity are social/cultural phenomena, not biological ones. Fortunately, due to increased creativity consciousness and efforts to teach creativity, the fourth-grade slump is disappearing. A third drop in creativity scores occurs in seventh grade as part of strong adolescent conformity. Most dynamics of conformity pressures are not mysterious. It simply is uncomfortable to be different and to challenge accepted ways of thinking and behaving. We learn that it is good to be correct and bad to make mistakes. We learn that being wrong can elicit disapproval, criticism, or even sarcasm and ridicule. Being different or wrong raises fears of being judged foolish, incompetent, or stupid.

Expectations and conformity pressures also work in more subtle ways. The traditionally perceived role of females – overloaded with expectations and stereotypes – is a slow-changing difficulty that is yet to be overcome. There are also pressures to be practical and economical, which can discourage 'idea people.' We learn not to ask too many questions – although curiosity is a core characteristic of creativity. We learn that fantasy is a waste of time, that we should have faith in reason and logic, and that we should not 'rock the boat.' If cooperation is an accepted cultural or institutional goal, many people will temper their creative ideas in order to 'fit in.'

Van Gundy noted such subtle corporate cultural barriers as a reluctance to share ideas, a fear that innovation will change the uniqueness of the organization, a desire to protect the *status quo*, and the attitude that "creative types don't fit in."

Finally, the greatest cultural barrier is the culture itself. Western psychology traditionally ignores monumental cultural differences in creative attitudes and personality, creative productivity, creative opportunity, and general self-actualization. Think for a moment of the anticreative forces of tradition, conformity, and traditional roles of women in Spanish- and Arabic-speaking countries and many places in Asia, India, and Africa.

Emotional Barriers

Emotional barriers interfere with thinking by making us 'freeze.' You may wish to imagine a balance scale with 'emotional upset' or 'freezing' on one side and clear thinking on the other. As one side goes down, the other goes up. Some familiar emotional blocks are anger, fear, anxiety, hate, and even love. Some are temporary states, caused perhaps by problems with peers, parents, partners, or children, or by pressures and worries at school or work, financial stress, or poor health. More permanent emotional blocks include chronic sources of insecurity and anxiety such as fear of failure, fear of being different, fear of criticism or ridicule, fear of rejection, fear of supervisors, timidity, or shaky self-esteem.

While most emotional barriers interfere with the creation of ideas, some will block their adoption and implementation, for example, fear of taking risks and fear of uncertainty. Also, differences in needs and values may produce conflict and block the acceptance of an innovation. While this article is not psychotherapy, one possible avenue for resolving emotional barriers is a two-step creative problem-solving approach: First ask what the problem is, and then ask what we can do about it.

Resource Barriers

Resource barriers may seem a trivial form of barrier to creative thinking. However, they can and do stop creative productivity. As suggested by the name, resource barriers include shortages of people, money, time, supplies, and/or information that are needed for creative thinking, or for the implementation of creative ideas. Conflicts are likely if resources are pirated from one department to develop an innovation in another.

Stimulating Creativity by Removing Mental Barriers

Roger Von Oech's book, *A Whack on the Side of the Head*, addresses the problem of teaching creativity as a matter of removing ten mental blocks – which sometimes requires a "whack on the side of the head." Space permits just a short review.

His first mental block is 'The Right Answer,' referring to the usual assumption that there is just one right answer. Rather, a creative person will look for the second, third, fourth, and so on right answers, which are likely to be more imaginative than the first. The second mental block is 'That's Not Logical,' which stems from our culturally rooted assumption that logical thinking is better than illogical thinking. With creativity, logical thinking is often best suited for an evaluative phase. A third mental block is 'Follow the Rules,' which means

thinking of things only as they presently are, not as they could be. Rule-inspecting and tradition-inspecting may be in order. 'Be Practical' is the fourth mental block, which can interfere with the imaginative asking of that pivotal question, 'What if ...?'

The fifth mental block is 'Avoid Ambiguity.' In fact, ambiguity is a subtle form of motivation that inspires imaginative thinking. Ambiguity is also an essential stage that occurs while we clarify a problem and consider possible solutions. Von Oech's sixth barrier is the assumption that 'To Err Is Wrong.' Innovation necessarily requires making mistakes and even failing, as Thomas Edison did quite regularly. Errors serve as stepping stones. Von Oech noted IBM founder Thomas J. Watson's quote, "The way to succeed is to double your failure rate." A seventh block is the notion that 'Play Is Frivolous.' In creative thinking, the wrongness here is obvious. Countless innovations and discoveries are born via playing with ideas.

Barrier number eight is 'That's Not My Area.' This rich block supplies an excuse for not even trying to solve a problem. Further, such a block prevents a thinker from looking to other fields for ideas and inspiration. 'Don't Be Foolish,' barrier nine, is a cultural barrier rooted in conformity pressures. 'Fooling around' with ideas, like playing with possibilities, is a popular creative thinking occurrence. Finally, the tenth block is the self-squelcher, 'I'm Not Creative.' This one is a self-fulfilling prophecy – if you believe it, you will be right.

Idea Squelchers

There are dozens of attitude-related idea squelchers which we use too often to stifle our own or others' creative thinking. As just a sample:

We've never done that before.
 Are you nuts?
 It's not in the budget.
 It can't be done.
 It's a waste of time.
 It has limited possibilities.
 Too academic.
 This is the last try.
 I'm telling you, it won't work.
 You ask too many questions.
 Don't step on any toes.
 It won't work in our neighborhood.
 We did all right without it.
 Let's discuss it at some other time.
 You've got to be kidding.
 See? It didn't work!
 You don't understand the problem.
 Let's wait and see.
 We can't do it under the regulations.
 It'll mean more work.
 Somebody would have suggested it before if it were any good.
 No adolescent is going to tell me how to run this operation!

A good case could be made for the argument that all of us would be more creative were it not for external and internal barriers, blocks, and squelchers. Because of well-learned habits, an unsupportive or repressive environment, or our fears and insecurities, most people do not use their creative imaginations and abilities.

The challenge to anyone wishing to increase their personal creativeness is to understand, expect, and be ready to cope with barriers to creativity from the environment or from inside oneself.

Creative Attitudes

When we discuss creative attitudes we are also speaking of creative personalities. Decades of research with creative individuals, including persons who have and have not achieved creative eminence, focused on their attitudes and personalities, compared with controls. As noted at the outset, *creativity* is most appropriately viewed as a way of living, thinking, and perceiving one's world. Creativity is rooted in one's attitudes and personality. This section will review recurrent patterns.

Over 200 adjectives and brief descriptions of creative attitudes and personality traits were sorted by the author into 15 intuitively defined categories of positive, socially desirable traits and seven categories of negative, potentially troublesome traits. The 'positive' versus 'negative' judgments were subjective, as were some ambiguous decisions (e.g., whether to place 'adventurous' under 'risk-taking' or 'energetic'). The categories interrelate in the sense that all can be part of the stereotypical 'creative personality.' Of course, not all traits will apply to all creative persons; there are simply too many forms of creativity and creative people. Some traits even are contradictory, for example, 'receptive to new ideas' versus 'sarcastic.' Finally, artistic/poetic creative people may be shy and withdrawn, not high in the energy, confidence, and humor that characterize the stereotyped creative person. The categories of traits reflect the main, recurrent traits of creative people as found in the literature. The 15 categories of positive traits appear in **Table 1**. The traits are mostly self-defining. However, we will comment briefly on each.

- *Aware of creativeness.* Most highly creative people are quite aware of their creativeness. They are in the habit of doing things creatively and they like being creative. Creativity consciousness is a common and important trait among creative people. *In improving our own creativity and in teaching creativity to others, creativity consciousness is the number one trait to develop.*
- *Originality.* The trait of *originality* is so basic that dictionaries often use the term interchangeably with *creativity*. Originality also may be considered a creative ability in the sense of one's capability for uniqueness and nonconformity in thought.
- *Independence, risk-taking.* These two traits interrelate closely, since a person cannot display high independence without the accompanying willingness to take a creative risk. The creative person must dare to differ, make changes, challenge traditions, make waves, and bend rules. Such independence and risk-taking expose the creative person to possible criticism and embarrassment, and the possibilities of failure or looking foolish.
- *High energy.* A defining trait of creatively productive people is their extraordinarily high level of energy, which appears as enthusiasm, driving absorption, passionate interest, and an unwillingness to give up. Paul Torrance called it the *blazing drive*. Psychologist Calvin Taylor once quoted a

Table 1 Sample of recurrent attitudes and traits of creative people

1. <i>Aware of Creativeness</i> Creativity conscious	Values originality and creativity
2. <i>Original</i> Flexible in ideas and thought Challenges norms and assumptions Resourceful Full of ideas	Avoids perceptual sets Sees things in new ways Is a 'what if?' person Imaginative
3. <i>Independent</i> Self-confident Individualistic Does not fear being different	Sets own rules Dissatisfied with the status quo Internally controlled, inner directed
4. <i>Risk-taking</i> Courageous Not afraid to try something new Willing to cope with failure	Does not mind consequences of being different Rejects limits imposed by others
5. <i>Energetic</i> Adventurous High intrinsic motivation Overactive, hyperactive Enthusiastic	Driving absorption Drive for accomplishment and recognition Persistent, persevering Sensation seeking
6. <i>Curious</i> Experiments Wide interests Likes to hear others' ideas	Asks many questions Open to the irrational Seeks interesting situations
7. <i>Sense of humor</i> Childlike freshness in thinking Plays with ideas	Playful Sharp-witted
8. <i>Attracted to complexity</i> Attracted to the mysterious Attracted to the asymmetrical Attracted to ambiguity, incongruity	Attracted to novelty Is a complex person Tolerant of disorder
9. <i>Capacity for fantasy</i> Animistic and magical thinking Had imaginary playmates as a child Mixes truth and fantasy/fiction	Believes in psychic phenomena and flying saucers Theatrical interests
10. <i>Artistic</i> Aesthetic interests Sensitive to beauty	Enjoys art, music, creative dramatics Good designer
11. <i>Open-minded</i> Liberal Receptive to new ideas	Open to new experiences and growth Receptive to other viewpoints
12. <i>Needs alone time</i> Internally preoccupied Prefers to work alone	Introspective Reflective
13. <i>Intuitive</i> Perceptive Sees relationships, implications Good at problem finding	Observant Uses all senses in observing Heightened sensitivity to details, patterns

(Continued)

Table 1 (Continued)

14. <i>Emotional</i> Can express feelings, emotions Sensitive Moody	Has emotional highs and lows Withdrawn Needs attention, praise, support
15. <i>Ethical</i> Altruistic	Empathic Democratic minded

scientist as claiming, with tongue in cheek, that the only way to stop a fellow scientist from working on a problem would be to shoot him. Frank Farley, past president of the American Psychological Association, frequently emphasized the *thrill-seeking* trait of creative people.

- *Thorough.* Of course, high risk-taking and energy are not enough. The committed creative person must finish the projects, preferably in an organized fashion.
- *Curiosity.* Along with originality and high energy, another classic trait is curiosity – a sometimes childlike sense of wonder and intrigue, a desire to understand one's world. He or she may have a history of taking things apart to see how they work and of exploring attics, libraries, and museums.
- *Humor.* Another frequent trait is a keen sense of humor. It relates to one's ability to have a childlike and playful approach to problems. Many discoveries, inventions, problem solutions, and artistic creations are the result of 'fooling around' with ideas, playing with strange possibilities, or turning things upside down, backward, or inside out. A relevant quote is that "the creative adult is essentially a perpetual child – the tragedy is that most of us grow up" (Fabun, 1968, p. 5). Both Freud and Carl Rogers agreed that regression to a childlike state is an important feature of fantasy and creative thinking.
- *Attraction to fantasy, complexity, and novelty.* The creative person's attraction to fantasy, complexity, and novelty may reflect the person's own complexity. A classic demonstration by Frank Barron and George Welsh showed that creative persons preferred smudgy, complex, asymmetrical drawings over simple and balanced ones. While novel ideas and innovations may excite creative people, others habitually may analyze defects and find fault. Tolerance for ambiguity, which relates intimately to complexity and novelty, is essential in the sense that – as we saw in Von Oech's fifth mental block – creative problem solving involves an ambiguous period in which the problem is clarified and solutions considered. One unique twist to the attraction to fantasy, complexity, and novelty is that creative people tend to be stronger believers in psychic phenomena and flying saucers, despite their generally higher intelligence level.
- *Artistic.* Artistic and esthetic interests usually are keen. One explanation is simply that creative people are more likely to have been involved in, for example, music, dance, theater, art, or handicrafts. However, the trait extends to persons creative in science, business, and other traditionally non-art areas.

- *Open-minded*. A creative person, virtually by definition, must be receptive to new ideas and willing to look at problems from various points of view. Open-mindedness includes not fearing the new, different, or unknown and not making up one's mind in advance. The trait relates to Von Oech's creativity barriers of looking for just one right answer, being practical and logical, and avoiding ambiguity, frivolity, mistakes, and foolishness.
- *Needs for alone time*. The need to create demands time for thinking, reflection, solving problems, and creating. Creative children and adults often prefer to work alone, reflecting their creative independence.
- *Perceptive*. Perceptiveness and intuitiveness, whether in art or science areas, are common traits of creative people. There is greater sensitivity to details, patterns, implications, relationships, and 'what should follow.' Intuitive "mental leaps" are quicker.
- *Emotional*. The Dabrowski and Piechowski phenomenon of 'emotional giftedness' or 'overexcitability' usually happens in very high IQ gifted persons. The syndrome includes free play of imagination, vivid imagery, fantasy, paranormal thinking, metaphorical thought, inventions, and poetic and dramatic perceptions, as well as fast talking and extra high energy levels. The syndrome includes having emotional highs and lows, moodiness, and emotional sensitivity.
- *Ethical*. Another trait related to high mental ability and creativity, and one found in Terman's early studies of highly gifted children, is a tendency for ethical thinking and behavior – empathy, idealism, altruism, and simple helpfulness.

Negative Traits of Creativity

A discussion of creative attitudes and personality would be incomplete without acknowledging traits and dispositions that disturb supervisors, parents, teachers, and peers. **Table 2** lists negative, sometimes upsetting characteristics of creative individuals that surfaced in the search for creative traits mentioned earlier. The traits may stem from a creative student's independence, unconventionality, persistence, and perhaps curiosity and humor. The items were placed into the seven categories of *egotistical*, *impulsive*, *argumentative*, *immature*, *absentminded*, *neurotic*, and *hyperactive*. Many are likely to cause personal or social adjustment problems.

Creativity, Psychoses, Neuroses, and Sociopathy

Another aspect of the creative personality that cannot be ignored is the tendency for a small proportion of creatively productive persons to be slightly mentally disturbed, and even to have mentally ill relatives. For example, in their 1950s study of the creative personality at the University of California at Berkeley, Frank Barron and Donald MacKinnon found a tendency for high-level creative people, such as creative women mathematicians, to be rebellious, undependable, irresponsible, and inconsiderate, and to have fluctuating moods. Barron and MacKinnon's creative writers scored in the top 15 percentile on *Minnesota Multiphasic Personality Inventory* measures of psychopathology: *hypochondriasis*, *depression*, *hysteria*

Table 2 Recurrent 'Negative' traits

1. <i>Egotistical</i>	
Intolerant	Snobbish
Self-centered	Claims the rest of the parade is out of step
2. <i>Impulsive</i>	
Acts without planning	Capricious
Careless	Disorganized with unimportant matters
	Tactless
Impatient	
Irresponsible	
3. <i>Argumentative</i>	
Cynical	Defiant
Rebellious	Sarcastic
Uncooperative	Stubborn
Little regard for rules, conventions, mores, law, authority	Autocratic
4. <i>Immature</i>	
Childish	Silly
Sloppy	
5. <i>Absentminded</i>	
Forgetful	Careless
Mind wanders	Watches windows
6. <i>Neurotic</i>	
Aloof	Mildly sociopathic
Temperamental	Unable to control emotions
Low frustration tolerance	Uncommunicative
7. <i>Hyperactive</i>	
Overactive, physically and mentally	

(anxiety, uncontrolled behavior), *psychopathic deviation*, *paranoia*, *psychasthenia* (fears, phobias), *schizophrenia*, and *hypomania*. However, strong *ego strength* scores indicated they could better deal with their troubles. Psychologically, said Barron, they were both sicker and healthier than the average person.

In a 1988 study of historically eminent persons, Herbert Walberg concluded that about a fourth to a third showed definite introversion or neuroses. Also in 1988 Solomon and Winslow reported that a sample of business entrepreneurs showed mild sociopathy and/or were social deviates. A 1995 study of male and female eminent persons by Walker, Koestner, and Hum indicated that the creative achievers were rated significantly higher than average on impulsivity, depression, and general neuroticism. Richards turned the usual procedure around, finding that a sample of manic-depressives were rated higher in creativity than were controls. Concluded Barron, 'mad as a hatter' is high praise when applied to creative people. The relationship continues to be an intriguing one.

Conclusions: Attitudes that Overcome Barriers

We have seen that blocks and barriers – learning and habit, rules and traditions, and perceptual, cultural, and emotional barriers – will interfere with creative thinking and innovation. Again, a common argument is that we all are born creative, but early years of socialization and education create habit- and tradition-based barriers to imaginative thinking and innovation.

We have also seen that all creative people show a relatively recurrent syndrome of creative attitudes and personality traits – awareness of creativity, originality, independence, energy and

motivation, risk-taking, curiosity, humor, attraction to complexity and fantasy, artistic interests, open-mindedness, and perceptiveness.

Of course, creative attitudes and personalities plus overcoming personal and environmental barriers do not present a total picture of the creative person. For example, other important factors discussed in this encyclopedia are intelligence and thinking styles, innate creative abilities related to the specific medium (e.g., art and mathematics), training, an existing body of knowledge, plus such matters as opportunity and chance. Nonetheless, an awareness of necessary creative attitudes and personality traits and a readiness to deal with environmental and personal barriers are central to creative development and productivity.

As to the puzzle in Section II, try removing S-I-X L-E-T-T-E-R-S.

Early Years

In the mid 1950s, British youth was exposed to rock 'n' roll arriving from the United States. The musical excitement inspired a number of British teens to learn an instrument associated with the new musical form. In Liverpool, Paul McCartney, John Lennon, Ringo Starr (Richard Starkey), and George Harrison sought to emulate their American idols Elvis Presley, Little Richard, Jerry Lee Lewis, and Chuck Berry. They were also influenced by American country and western artists.

Building the capabilities for success began in their teenage years with support and encouragement from their families. At the age of 16, John Lennon's mother, who played the banjo, taught Lennon banjo chords and encouraged him to learn the guitar. George Harrison, who was three years younger acquired his first guitar in his early teens, and Ringo was about 16 when he bought his first bass drum. Paul McCartney also benefitted from parental support and instruction. Paul's father was an amateur jazz musician and provided Paul with the best musical education of the four. John Lennon notes that when they first met, Paul could play guitar, trumpet, and piano. By contrast, John could only play the mouth organ and two chords on a guitar. Another important capability Paul learned from his father was the ability to sing in harmony. Defining vocal harmonies would become a key role for Paul in the Beatles.

Although Paul was the better musician, John was developing other capabilities that would contribute to the creative process. He had been composing verses and stories, with a strong influence by Lewis Carroll. Although both Paul and John could write capable music and lyrics, these early differences were to characterize their creative output throughout their careers.

With little in the way of instruction or sheet music, John and Paul studied new records as they came out, noting the words, and analyzing the chord changes. They spent a lot of time trying to figure out the chords, and in so doing, gained an understanding of chord structure and progressions that they would later use in their own songs. The motive for Lennon and McCartney was not just to become rock and roll performers. They dreamed of becoming the next great song writing team and often bunked school to write songs in their living room. Paul McCartney describes their early song writing:

We started off I think with a song called "Too bad about sorrows". They all had simple chord structures but we learned our craft that way ... we'd do some good rhythm on the guitars, and we probably harmonised a little together. ... We just developed the art, gradually, gaining in confidence. So we did this every so often through a number of months. (Miles, 1997: 36)

By analysing the songs of the imported music they expanded their performance repertoire and by 1960 the Quarrymen, as they were then known, could perform over a hundred songs. They gave a number of live performances in the

United Kingdom before gaining employment in Hamburg's Reeperbahn district. For two years, they divided their time between Liverpool and Hamburg, further developing their performance capabilities and methods of working with each other. Their ability to harmonize tightly was one of the skills developed further during this time.

Live performance also increased their motivation to write their own songs. Competition between bands was acute, and the Beatles needed to distinguish themselves from the other acts. Their first response was to play the B side songs from records as these were little known. However, the Beatles only needed to play them once before the other groups became aware and copied them. So they decided they had to find their own identity and write their own material which they began to introduce into their performances.

While playing in Liverpool, the group came to the attention of Brian Epstein who managed a local record store. After hearing them play in the Cavern night-club, Epstein offered to be their manager. He tidied up their presentation, and approached a number of record companies in pursuit of a recording contract. All the companies rejected them, an indication that there was nothing special about the Beatles or their music at this stage. As a last resort, Epstein approached the EMI comedy label Parlophone. The label was managed by George Martin who although, specializing in comedy, was on the lookout for a musical act. Like the other record companies, Martin was unimpressed by their demo-tape, but he felt they had potential and was particularly struck by their charisma. He was not impressed by their song-writing ability as their early compositions showed no indication of what would come. Their best song *Love Me Do* was very simple, and they did not have enough marketable material to fill an album. Their first two albums both needed six covers of American songs in order to have sufficient material.

John and Paul had a strong ambition to develop their song-writing. They often wrote songs together, partly because they enjoyed it and partly because it was more productive. The level of collaboration could vary and some songs could be called 'solo' efforts, even in the early days; however, a common practice was for either John or Paul to have an idea and this would lead to the composition of the first verse, from which the other would help build the rest of the song.

An idea for a song could come at any time, sparked by any item of interest including newspaper articles, circus posters, or fantasy romances. Lennon often wrote about personal issues, the songs being outlets for his emotions. A common pattern was to write a song in imitation of their American idols, for example, John's song *All I've Got To Do* was written as an attempt to emulate Smokey Robinson and the Miracles. Another technique was to pluck lines or phrases from other songs, then take them in different musical directions. For example, the song *Run for Your Life* had its roots in the Elvis song *Baby Let's Play House*. The original idea provided the

foundations on which they would build introductory phrases or theme for the lyrics; the foundations for the first verse.

The first verse would give the tune, tempo, key and subject matter. Once the idea had been converted into a first verse, it was common for the writer to get stuck over what to do next. This is where they would use their cowriter to overcome the block. John Lennon describes how:

... the way we wrote a lot of the time was you'd write the good bit that was easy, like "I read the news today, oh boy" ... And then when you got stuck, ... you'd just drop in and meet each other and I'd sing half and he'd be inspired to write the next bit and vice versa. (Wenner 1971: 115)

Lennon also suggests that writing in this way increased the level of experimentation, because "you tend to be a bit lax with somebody else's stuff – you experiment a bit" (Ibid.). The section where the second composer helped was frequently called the middle eight, even if it had 32 bars. A typical Beatles song had four verses, a chorus that was repeated and a middle eight. So if John had a first verse, Paul would come in "at the second verse, be there for the middle eight and be there for the third and fourth verses, the resolution" (Miles, 1997: 177).

On tour, many songs were written backstage, in tour buses or in hotel rooms. The need to fulfil recording contracts provided a disciplinary pressure that led to highly productive song-writing bouts. They would normally be given two week's notice that the recording studio was booked and this created a deadline to provide new material by. Paul McCartney would go to John's house every day for the week and each day they would write and work on each other's songs. Even when alone, they would run over the other's song to see if they could improve it.

A song once written would be taken to the studio and performed for George Martin to hear. John and Paul sang their song while playing the acoustic guitar. At this stage, Ringo and George would not be involved unless George joined in the harmony. George Martin would make suggestions for improvement and they would try it again, creating what is known as the 'head arrangement.' George Martin notes:

We established the working format that whoever wrote the song generally sang it, and the others would join in. If it were John's song, he would sing it, and when we came to the middle eight – the section in the middle of a song where the tune changes – Paul would sing thirds above or below, or whatever; if a third part were needed George would join in. It was a very simple formula. (Martin and Homsby, 1979: 132)

This simple pattern of production characterized the first phase of creativity, which included the songs *Love Me Do*, *Please, Please Me*, *From Me to You*, *She Loves You*, and *I Want to Hold Your Hand*. Each song had a very distinctive sound underlined by their strong harmonies while their singles were characterized by fast energetic tempo. John Lennon says their distinctiveness was simply due to the fact that they did not sound like the early artists. Songs written in imitation of black American artists would have a different sound when sung by white English men. This could be seen on the song *The Long and Winding Road*, written much later. Paul wrote it with Ray

Charles in mind but noted "It doesn't sound like him at all, because it's me singing and I don't sound anything like Ray, but sometimes you get a person in your mind, just for an attitude, just for a place to be." (Miles, 1997: 539)

By 1963, they had perfected the basic tenets of composition and produced dozens of classic pop songs. They made a conscious effort to develop their writing and their songs and harmonies were becoming more sophisticated. They would look at what others were doing and were keen to integrate improvements. For example, on hearing *Besamo Mucho* by the Coasters (1960), Paul noticed it changed from a minor key to a major key and this created a big moment musically, so on the song *From Me to You*, he changed from a major to a minor key for the first time. Their lyrics also became more sophisticated moving from simple love songs to cover a broader range of issues.

This process of continuous improvement was driven by artistic curiosity, a desire to improve, and a competitive rivalry between John and Paul. They constantly competed to have their songs on the A side of the singles and this put pressure on them to improve. However, it was a co-operative rivalry. They had earlier made a decision that both their names would go on their songs no matter who wrote it. Hence they shared the royalties, as well as performance income. So although they competed, they had a strong incentive to cooperate.

They were also writing songs for other groups. Billy J. Kramer and the Dakotas received four originals including *Do You Want to Know a Secret* which knocked the Beatles off the top of the UK charts. The McCartney song *World Without Love* was performed by Peter and Gordon and it too pushed the Beatles song *Can't Buy Me Love* off the no. 1 chart position. To ensure that the success was not a result of the McCartney name, Paul gave them another song *Woman* under the name Bernard Webb. It went to no. 1 in the United Kingdom and no. 2 in the United States. But not every song was successful. Paul would try to bury his poorer songs but came under pressure from artists wanting material.

Transition

The Beatles fifth album *Help!* contained a song with a dramatic change of form. This was *Yesterday*, a song written solely by Paul McCartney which came to him in a dream. George Martin convinced a reluctant Paul to use a string quartet for instrumentation. George Martin wrote the arrangement with suggestions from Paul. This use of a string quartet on *Yesterday*, and a flute on the song *You've Got to Hide Your Love Away* were the first occasions where, under George Martin's guidance, the Beatles expanded beyond their own rock n roll instrumentation. No longer would they be limited to a bass, two guitars, and drums.

These changes were embodied in the next two albums, *Revolver* (1965) and *Rubber Soul* (1966) which reflected the Beatles transition from a singles band to a studio band. On *Rubber Soul*, greater use was made of the keyboards, while George Harrison introduced an Indian instrument, the sitar on the song *Norwegian Wood*. Much of this broadening in instrumentation can be attributed to expanded capability acquisition. At the same time as George Harrison was learning the sitar, Paul McCartney was gaining greater exposure to classical music, not just from George Martin but also from his

girlfriends, Jane Asher's family who increased Paul's exposure to classical instrumentation. On the *Revolver* album, strings were effectively used on *Eleanor Rigby*, a song written by Paul who was talked into using strings by George Martin who did the arrangement. Not wanting a Mantovani sound, Paul instructed Martin he wanted the strings to sound really biting. George Martin's musical skills were also drawn upon devising complex harmonies for the boys to sing on the album.

Aware that they were EMI's cash cow, at the same time as gaining greater technical expertise, the Beatles started to take control of the studio. In earlier days, they would take what George Martin gave them. Now they were more precise about the sound they wanted on the final product. They often told George Martin what they wanted and this in turn, forced the producer and engineers to be more innovative. Sound engineer Geoff Emerick notes that it "was during the *Revolver* sessions that I realized I simply couldn't rely on textbook recording techniques in terms of mic positioning and placement. The Beatles were demanding more, so much more of both me and of the technology." (Emerick 2006: 128)

Much of the Beatles work could be described as research and development in sound. All four Beatles had bought themselves open-reel tape recorders and this allowed them to experiment at home. Paul discovered that the erase head could be removed, allowing new sounds to be added to existing ones. Although, the tape quickly became saturated with sound, the distorted sounds gave birth to a rush of R&D activity, and the four would often bring in bits of tape in a de facto "weird sound contest" (Ibid.: 111). For John's song *Tomorrow Never Knows*, Paul created a series of short loop tapes which he played to the others in the studio the next day. The four would listen to each and choose the ones they preferred. On another occasion, John Lennon thread the tape backward on his machine by mistake. The resulting sound appealed to the four who then wanted backwards sounds on almost every over-dub on *Revolver*.

George Martin's previous experience producing comedy records was drawn upon for the song *Yellow Submarine*. Experienced at making sound pictures, he and his engineer overdubbed nautical sounds from EMI's sound effects library. Martin gained the distinctive brass band effect by cutting up a recording of Sousa's marches, mixing up the pieces and splicing the mixed pieces together. Initially done to overcome copyright controls, it was a technique he would use again on *Mr Kite* on the *Sgt Pepper* album.

In the earlier albums, George Martin would simply record the songs that the Beatles had performed live, but for the *Revolver* album there had been no prior performance. All the tracks were created in the studio. The complexity of the albums was such that a much longer time was needed to create them. Compared to the early albums that could be recorded in a day, *Revolver* was recorded in just over ten weeks. The song *Here, There and Everywhere* took three days by itself.

The two transition albums were also characterized by a significant contribution to the creative process by George Martin and a change in his role as producer. Although the Beatles gained control of the studio at this time, ironically this meant that George Martin would have greater influence on the music as he sought to bring their images to life. In the early days, Martin's work was not different to any other good producer. He basically reproduced the songs as they were

performed in the Cavern. There wasn't much arranging to do however; new songs would require more work. For example, the song *Please, Please Me* was much slower and in a very different form. George Martin suggested adding harmonies and a harmonica, and lifting the tempo creating the fast Beatles energy we recognize with the early period. The song was also too short so he suggested some structural changes such as singing the chorus twice, along with suggestions on how it should be done. However there was little in the way of arranging. On the other hand, the song *I Want to Hold Your Hand* recorded a year later, needed little improvement on the original apart from some minor changes in tempo and vocal harmony (Ibid.: 71). This changed in 1965 with the song *Yesterday* when he began to score orchestral arrangements, a unique attribute for a producer given his study at Guildhall school of music. Martin differentiates between orchestration and composition saying:

Orchestration is a matter of giving colour to lines that are already there . . . The basic design doesn't change. What orchestration does is to give it life . . . I tend to think of orchestration in terms of painting a picture. An artist can do a brilliant outline sketch in sharp charcoal, Picasso for example. . . . But when it comes to orchestration, what you do is to fill in all the subtle colourings, making the picture into a three-dimensional form. (Martin and Hornsby, 1979: 34–36)

Martin praises Lennon and McCartney for their ability to craft a tune. "A tune is one fingered, something that you can whistle. . . . The ability to create them is simply a gift" (Ibid.: 139–140). However, Martin's emphasis on melody understates his own contribution as harmony, orchestration, and other aspects he provided can be considered aspects of composition.

Technical advances aided the creative process. Multitrack recording meant that instruments could be recorded at different times. The producer could change his mind half way about aspects of composition without starting again. But it was the advent of stereo recording which enabled the producer to become a creative person in his own right. No longer was the producer restricted to replicating a live performance. Now he could introduce artificial sounds and a sense of movement. On the *Sergeant Pepper* album, stereo was used for a number of effects, with instruments floating from side to side, "giving the listener the impression that it was almost flying over head." (Ibid.: 116)

Other technical tools included multispeed techniques like doubling or slowing the music's speed, playing sounds backwards, and other unusual sounds effects. All contributed to the ability to build a sound picture. George Martin's contribution appears to be greatest on songs written by John. Although John was full of ideas about the sounds he wanted it was Martin and his engineers who had to create that vision. Lennon had little knowledge of technology and had trouble giving direction in musical terms. George Martin contrasts his ability to Paul McCartney:

Paul would sit down and ask what I planned to do with his songs, every note virtually. "What do you think the cellos should be doing here George?", and I'd have to describe to him on the piano what it would be. He'd say: "Yeah. OK, but what about changing that note?" Lots of the arrangements to his songs were very much his ideas which I would have to implement.

John would be more vague in what he wanted. He would talk in metaphors about his ideas . . . he'd say for example on "Being for the Benefit for Mr Kite!" – this songs about a fairground. A little bit mystified. I want to get the feeling out of the sawdust and the feel of the ring. Can you do something about it?

Competition with other artists provided another incentive to raise quality. In the mid-sixties, the Beatles had a "curious Transatlantic slugging match" (Martin, 1994: 49) with The Beach Boys, an American pop group who severely felt the impact when the Beatles stormed the US charts. Until that time, The Beach Boys song *Surfin USA* held the sales record, but when the Beatles single *I Want To Hold Your Hand* was released in the United States, it took the record, selling 500 000 copies in less than a week. The Beach Boys next single *Fun, Fun, Fun* could not get above five in the charts because the Beatles held the top four spots. This inspired the Beach Boy's composer, Brian Wilson, to improve and write a string of number one hits, including *Help Me Rhonda*, *I Get Around*, and *Good Vibrations*. By 1966, the *New Musical Express* reader's poll ranked the Beach Boys as the most popular group in England, ahead of the Beatles.

While the groups competed with each other, there was also a strong degree of admiration. Both analyzed each other's output. The Beatles were particularly impressed by the Beach Boy's album *Pet Sounds* with its unusual use of instruments and intricate harmonies. This inspired the Beatles to raise their standards yet again on their next album, *Sgt Pepper's Lonely Hearts Club Band*.

Creative Climax

If *Rubber Soul* and *Revolver* could be described as the transformation stage, *Sgt Pepper* and the songs on the *Magical Mystery Tour* album were the climax resulting from that transformation. By November 1966, the group had an unprecedented string of hits that included 12 singles all going to no. 1 in the charts and seven no. 1 albums. They had the confidence to know they could try anything they wanted and this fostered experimentation and creativity. Success had also given them more resources than any other pop group had available to them, in particular, time in the recording studio.

Paul devised a concept for the *Sgt Pepper* album in which the group would develop an alter ego, the *Lonely Hearts Club Band*. Although the concept was only carried through on two of the songs, the fact that they did not have to project an image from the old group image freed the Beatles from their traditional musical landscape.

The sense of innovation could be seen on the first song of the recording session, *Strawberry Fields* written by John about a place he knew in Liverpool. Lennon brought a new instrument to the studio with him. A mellotron, a keyboard instrument with a number of sound settings. Paul dialled up the flute sound and experimented with the chords to the song. Soon he had a stunning opening arrangement to complement Lennon's vocal line. Another novel instrument was the sword-mandel, an Indian instrument introduced by George Harrison. Towels were placed over the drums to create a muffled tone while the cymbals were recorded and played backwards.

George Harrison experimented with sweeps on a slide guitar he had just bought, and a piano was plucked instead of using the keys. After two versions of the songs were mixed, John then decided he would like to see them joined together even though they were in different keys. This problem was solved by speeding one version up and slowing the other down.

Not all the experiments worked and some did not make their way onto the final recording, but the song embodied an R&D attitude to sound not seen before in popular music. Behind this was a drive for perfection, "it wasn't a question of being 99% happy with something; we all had to be 100% happy with it." (Emerick, 2006: 254)

George Harrison gave the album an exotic flavor with his Indian inspired *Within You Without You*. This song stretched Martin's ability as a producer as he had to combine an orchestra with Indian instrumentation. This aside, George Harrison and Ringo Starr played a small role on these sessions. The album took a long time to produce but required little of these two who were predominantly musicians not composers. Ringo got bored and learned to play chess, while George Harrison's heart was in India. Sound Engineer Geoff Emerick describes *Pepper* as being more like a John and Paul album, than a Beatles album.

By 1967, the Beatles had emerged as a powerful composition team, building musical images that no one else had done before. They were intrinsically inspired by the love of their work and extrinsically inspired by the success they gained. Aspects that contributed to the team's success included the group's cohesiveness which enabled each member to introduce new ideas free from censure by other members. This was underpinned by a high level of mutual trust and respect which facilitated co-operation and collaboration. Each was aware that sharing ideas was important to see them developed. They also valued each other's criticism, a key factor in the analysis and enhancement of their work.

Another key element of their success was the blend of different expertise and creative thinking styles in the team. McCartney's compositions were characterized by lightness, optimism, strong melodies, and an emphasis on the music. Lennon's music was often sad and discordant, often with bluesy notes. While McCartney's melodies danced around, Lennon's were often based on only one or two notes. McCartney's songs were driven by the music. The only song he wrote the words first was *All My Loving*. By contrast, Lennon focused on the words and was more inclined to write about his own feelings and experiences. During *Sgt Pepper*, he was consciously trying to write poetry. Lennon drew on surreal images similar to those that Lewis Carroll inspired in him as a teenager. In contrast, McCartney's lyrics had a reality to them describing characters like novelists, meter maids, and barbers.

The team also benefitted from a breadth of expertise. George Martin had significant expertise in music arrangement and technology while the four musicians possessed the necessary knowledge of rock'n roll. Lennon and McCartney always had an underlying ambition to go in an artistic direction, something that set them apart from other Liverpool musicians. It was George Martin that opened this door to them. Lennon and McCartney possessed what Amabile describes as creative thinking; a propensity to take new perspectives and take risks with little concern for social approval. They were constantly

looking for new sounds and willing to break established norms. This was fuelled by their success which gave them confidence to try new things. Their management and the record company were prepared to accommodate their wanderings because of their success. There were however, times when this creative freedom could go too far. At times, on *Magical Mystery Tour* George Martin felt the group went too far and lacked mental discipline.

Management appears to have a minor, but at times important impact on the Beatles. First it helped determine the initial success, which in turn determined the resources available to them. In 1963, the stable of artists managed by Brian Epstein, recorded by George Martin with music publication, and promotion by Dick James dominated the British charts. Of the 52 weeks of 1963, the Epstein-managed artists topped the charts 37 times. However, Epstein could have a negative effect. He committed the group to the movie *Yellow Submarine*, a project they had no interest in, which they used as a depository for poor quality songs. The record company was not the group's manager but contributed to the organizational framework. EMI may have done a good job at promotion and distribution of the music, but on a day-to-day basis seemed oblivious to the Beatles needs and the Beatles felt no loyalty towards the company.

It is significant that John Lennon makes a direct link to the group's eventual break up to the death of Epstein, stating that the Beatles broke up after Brian died. Management had protected the Beatles from many nonmusical distractions. After Brian's death the Beatles established 'Apple' a company that managed a number of artistic activities, but with extremely limited business skills. The company suffered and the musicians would often arrive in the recording studio carrying disagreements about the company. It was such a dispute that eventually led to the band's break up.

With Epstein's death Paul, took over leadership and is recognized as having saved the band. However, their subsequent projects often lacked the structure of the Epstein years. This could be seen in the Beatles next movie, *The Magical Mystery Tour*. Without directors or script writers, the movie was the group's first flop. Epstein's death also affected their song writing. Previously, Epstein organized recording dates and ensured that Lennon and McCartney's calendar was free of interference leading up to that time, thereby giving them time to write songs together. This no longer happened. Paul now organized the recording times. John Lennon notes that "Paul had a tendency to just come along and say 'Well (I've) written ten songs, lets record now.' And I said give us a few days and I'll knock a few off."

The problem was John was caught without any songs, and it is possible the *Magical Mystery Tour* sessions were begun too soon. But another process was at play; John's productivity was falling at a time when Paul was reaching a peak, a problem made worse by the reduction in cowritten songs. In the early days, John had arguably been the stronger writer. On a *Hard Day's Night*, he had been the predominant writer on seven of the songs, and cowrote three more with Paul, while Paul was dominant writer on only three. After this, Paul and John's contributions were roughly in balance, but with *Magical Mystery Tour* Paul emerged as creative leader. John was well aware of the situation:

You'd come up with a *Magical Mystery Tour*. I didn't write any of that except *Walrus*; I'd accept it and you'd already have five or six songs, so I'd think "Fuck it", I can't keep up with that so why bother. (Miles, 1997: 139)

In his defense, John claimed he had succumbed to marriage and eating, but there are other explanations. First, Paul was now benefitting from his greater investment in capability building. Paul was the workaholic who strived to expand his musical and technological knowledge while Lennon was relatively lazy. The result was Paul had more musical tools and components to work with. He was also more motivated, striving for perfection, an attitude John didn't share. There was one other explanation for John Lennon's decline in output – drugs.

The Beatles had been taking drugs since their days in Hamburg, when the waiters provided pills to keep their energy up during performances. At the time of the *Help* album they dropped the pills and drink and moved on to marijuana, and by *Sgt Pepper*, LSD was commonly used. The Beatles realized that drugs undermined the quality of their performance. A recording session affected by drugs needed to be redone at a later date, so they made a point of staying clean while recording. In terms of composition, drugs provided subject matter for songs such as *Day Tripper* and *Got to Get You into My Life*, but in the long term this probably had a detrimental effect. John Lennon, who took the greatest quantities of LSD and at times used heroin, experienced a significant drop off in output. By contrast, Paul McCartney, who largely restricted himself to marijuana continued to excel. Drugs may have also affected Lennon's ability to function in the group. About this time John's personality was changing and in subsequent years, his behavior would become erratic with frequent severe mood swings.

To the public, John's decline was masked by the heights of composition that Paul was achieving and the rise of George Harrison as a composer. Harrison had songs on Beatles albums as early as 1963 but the quality was marginal. Until this time, his greatest contribution to composition was arguably the Indian sonic textures he introduced. However, by 1968, Harrison was delivering strong songs, and on the Beatles last album *Abbey Road*, his song *Something* became the coveted single.

In February 1968, the Beatles went to India to the retreat of the Mahareshi Mahesh Yogi. This was a period of great creativity, with inspiration coming from the Mahareshi's words, the new experiences and new people, and the interplay with other artists like Donovan who were also on the trip. Paul wrote 15 songs on the trip while John, whose brain was free from drugs for the first time in years, also enjoyed a productive period. Many of the songs written in India made their way on to the *White Album* and *Abbey Road*. However, there was variation in their quality.

Slow Disintegration

The team dynamics that had driven the creative wealth on *Sgt Pepper* were sorely missing on the Beatles last three albums. For the first time, the Beatles were bringing their problems into the studio including business issues related to Apple Corporation. Also coming to the studio was John Lennon's new girlfriend, Yoko Ono. This was a huge intrusion on a group known for its

tightness, but if any of the others expressed their opinion, Lennon would lash at them with his tongue.

The divergent thinking styles that had previously contributed to enhanced creativity had grown bigger, creating a divide epitomized in John Lennon's abstract piece *Revolution no. 9*. The others were not opposed to abstract art. Paul had explored *avant garde* music well before John, however they didn't consider it Beatles music. George Martin and the other Beatles tried to persuade John to leave it off the album, but John was adamant. Under the influence of Yoko Ono, the song was his vision of where the Beatles should be heading. He wanted it released as a single.

The nature of the *White Album* also affected creative exploration. There appears to be a deliberate attempt to make a raw-sounding album, in contrast to the highly produced *Sgt Pepper*. Even the album cover, was simplified, being bland white with the exception of the Beatles name. This meant that George Martin and his engineers played a smaller creative role. The Beatles no longer asked the engineers to do the impossible. They were content with simple acoustic sounds, perhaps a reflection of context in India where many of the songs were written on acoustic guitar.

Co-operation on the *White Album* was at a low ebb with few suggestions passing between the two composers. They didn't seem interested in each other's opinions, and if a suggestion was made, it was normally rejected. They seemed to be saying "I don't like what you're suggesting because I don't like you" (Emerick, 2006: 254). It got to the point where they would not even record together. They split into small groups with their own engineer and worked in separate studios.

The creative team was disintegrating and the recording sessions became a nightmare for those involved. The sound engineers walked out and none of the other engineers at EMI wanted to replace them, an unthinkable position a year earlier. The atmosphere on the next album *Let It Be* was even worse. The sessions were so dysfunctional that George Martin eventually disassociated himself with the recordings which sat on the shelf until Phil Spector finished off production. Given the disaster of *Let It Be*, the Beatles made a conscious effort to be on their best behavior for what would become their last album, *Abbey Road*. Arguments still occurred but not on the scale of the previous sessions. One feature that made arguments less likely was they were rarely in the room at the same time. On previous albums, if one of them was recording, the others would hang around to give input and support, but on *Abbey Road* no one stayed behind. They were no longer working as a team.

The experimental days pressuring Martin and the engineers for novel sounds had long passed. In fact, the Beatles had built up so much experience that George Martin had to take a back seat on production. At times on *Abbey Road*, he contributed intricate harmonies, vocal arrangements, and orchestral scoring including nine part harmonies on John's song *Because*. Despite the situation, the album was driven by three accomplished composers and the industries top producer. It remains a landmark in pop music.

In the latter years, there were still moments when they worked together, for example, John took his *Ballad of John and Yoko* to Paul's house to help finish, and they still had a desire to see each other's songs improved, but the team work of old had long since passed. John wanted to explore conceptual art with

Yoko Ono and had already produced independent recordings. He was also battling drugs. George Harrison was no longer happy to operate in Paul and John's shadow. Ringo seemed exhausted, while Paul, who had offered leadership, was aggravating the others with his bossiness. A business problem at Apple Corp. provided the final spark for the bands demise.

Each of the Beatles went on to develop successful solo careers, and all four were regularly in the charts in the first half of the 1970s. Ringo had five top 40 albums and seven top 10 singles including two no. 1s. John had six top 10 albums including two no. 1s. His sales sky-rocketed after his death, including three chart-topping singles. George Harrison released the biggest selling album of all the ex-Beatles; his *All Things Must Pass* album. He had five top 10 albums in the first half of the 1970s before fading. However, he maintained an intermittent presence in the charts, including time in the group 'The Travelling Wilburys.' He also became a very successful financier and executive producer of films with his company *Hand Made Films*.

The most successful of the ex-Beatles was Paul McCartney. On leaving the Beatles he formed a new band 'Wings' with his wife Linda and Denny Laine. It had a string of platinum albums. In the 1980s, Paul collaborated with a number of artists including Stevie Wonder, Michael Jackson, and Elvis Costello. In the 1990s, he ventured into orchestral music, collaborating with Carl Davis to write *Liverpool Oratorio* performed by the Royal Liverpool Philharmonic Orchestra and the choir of Liverpool Cathedral. In 1997, he was knighted for his services to music. He is listed in the *Guinness Book of Records* as the most successful musician and composer in popular music history.

Glossary

Counterpoint The relation between two or more musical melodies that are independent in contour and rhythm, but which are harmonically interdependent. The adjectival form of counterpoint is contrapuntal.

Fugue A type of contrapuntal composition with a fixed number of parts or voices. Beethoven's late style includes a large proportion of fugues.

Opus numbers A numbering system used to categorize Beethoven's most important works. Opus (Op.; plural: Opp.) numbers represent 'official' compositions published during or shortly after Beethoven's lifetime. These run from Op. 1 to Op. 138 and sometimes include several works per Opus number (such as the three piano trios of Op. 1). Other works are usually given WoO (Werke ohne Opus) numbers.

Sonata form A musical structure consisting of three main parts: (1) an exposition in which melodic and harmonic material is introduced; (2) a development section in which the material is elaborated and contrasted; and (3) a recapitulation in which the material is resolved harmonically and thematically. Sometimes these three parts are preceded by a slow introduction. Sonata form is typical of works in genres in which Beethoven excelled, such as symphonies, piano sonatas, and string quartets – though usually the term strictly applies only to the first movement of such compositions.

Symphony A major musical genre, usually in four movements, scored for full orchestra and cast in sonata form. Beethoven's nine symphonies represent probably the highest peak in the development of this genre.

Introduction

Ludwig van Beethoven (16 December 1770 – 26 March 1827) was an enormously productive and influential German composer and one of the supreme creative personalities of all time. He is widely regarded as one among the greatest composers in the Western classical tradition. Informally, Beethoven has been ranked the 45th most influential person in *all* of human history, the only composer and one of only three artistic figures among the top 100. Besides being the subject of numerous biographies and critical studies, he has served as the subject of a case study for psychological inquiry, including historiometric studies in which archival data are used to test hypotheses about the nature of creativity and eminence.

This article is divided into two major sections. The first outlines Beethoven's life, career, and works. The second addresses several outstanding contemporary issues in the psychological study of creativity, where the life of Beethoven is particularly illuminating.

Life, Career, and Works

Beethoven's Life in Bonn and His Earliest Works

Ludwig van Beethoven was born in Bonn, Germany, probably on 16 December 1770, and was the oldest surviving child of Johann and Maria Magdalena van Beethoven. Beethoven adored his mother. His father, a tenor at the Electoral Court in Bonn who also taught piano, was a harsh disciplinarian and an alcoholic, which eventually led to his dismissal from the Court post. However, he began to impart his musical knowledge to his son as early as 1774, and Ludwig progressed rapidly enough to give a public performance on the piano in Cologne on 26 March 1778. The following year, he began lessons with Christian Gottlob Neefe, who became his role model and

taught Beethoven the rudiments of composition, even introducing him to Bach's then largely unknown Well-Tempered Clavier. Neefe, who instructed Beethoven throughout the 1780s, recognized his enormous talent, prophesying as early as 1783 that he could become a second Mozart (who was then only 27 years old!).

While not as precocious as Mozart (who was?), Beethoven excelled as a performer and began composing while still a child. His earliest surviving works, published in 1782 and 1783, were short piano compositions. Beethoven was not a prolific teenage composer, but he explored vocal and chamber forms; perhaps his most ambitious early work is a Piano concerto in E flat, WoO 4, written at the age of 13. A high point of Beethoven's early life was his journey to Vienna and meeting with Mozart in the spring of 1787. There are conflicting reports about whether Mozart actually heard Beethoven play. In any case, Beethoven was soon called back to Bonn because of his ailing mother, who died that July. He was unable to return to Vienna until after Mozart's untimely death in 1791.

In his late teens, Beethoven continued to develop as a pianist and gained experience as an orchestral violist, but wrote very little music – a hiatus that remains unexplained. By 1790, however, Beethoven got the opportunity to compose two cantatas scored for chorus, vocal soloists, and orchestra; one, the Funeral Cantata for Emperor Joseph II, WoO 87, was, at three-quarters of an hour, his longest work to date. These compositions, particularly the *Joseph* cantata, mark a considerable advance and foreshadow many aspects of his later works, especially those of his 'middle' period, 15 years later. Apparently unperformed in Beethoven's lifetime, the cantatas disappeared but were rediscovered in 1884; the great composer Johannes Brahms, one of the first to examine the *Joseph* cantata, exclaimed that it could only have been written by Beethoven. Once he had started, Beethoven was able to sustain, diversify, and develop his compositional output unabated for at least

two decades. Indeed, not too long after resuming regular composition, in 1792, he composed a set of variations for piano trio, later published as Op. 44, now recognized as his earliest contribution to the standard repertoire.

The Works of Beethoven's Early Period and the Onset of Deafness

By November 1792, shortly before his father's death, Beethoven was ready to move to Vienna, Europe's musical capital. There he pursued a career as a pianist and studied composition with Franz Joseph Haydn, then 60 years old and the most eminent musician in Europe, whose greatest successes were yet to come. Interestingly, Beethoven appears to have been deficient in certain aspects of musical technique when he arrived in Vienna. His study with Haydn involved hundreds of elementary counterpoint exercises, wherein Beethoven made quite a number of 'mistakes,' corrected by Haydn – but which in some cases became characteristic features of Beethoven's own style. The relationship between the two was complex and ambivalent. For instance, they disagreed over the merits of Beethoven's Piano Trio in C minor, Op. 1, no. 3. Beethoven once claimed that he never learned anything from Haydn, and did not seem to regard Haydn as a composer quite of the caliber of Mozart, Bach, or Handel. However, Beethoven dedicated his Op. 2 piano sonatas to Haydn and later spoke of him with respect. Haydn clearly recognized the enormous, if somewhat untamed, talent evident in the young Beethoven.

Haydn left Vienna for a long sojourn in London in 1794. Throughout the rest of the 1790s, Beethoven sought out new teachers to complete his musical training. With Albrechtsberger, he reviewed the fundamentals of counterpoint before tackling more advanced topics; with Foerster, string quartet composition; and with Salieri, multi-part vocal composition and Italian word-setting. Beethoven also made a name for himself as a performer, becoming one of the most renowned pianists in Vienna, known especially for his ability to improvise.

Beethoven also absorbed the influence of other composers during his twenties. While Haydn's formal instruction did not leave a strong mark on Beethoven, Haydn's own music did, in virtually every aspect of his composition. Equally important was the influence of Mozart, on whose music Beethoven directly modeled a number of early works, including three early Piano Quartets, WoO 36, the Piano Quintet with Winds, Op. 16, and the Third Piano Concerto, Op. 37, of 1800. For his piano sonatas, Beethoven found models in Clementi, Dussek, Cramer, and others of the 'London Pianoforte School.'

Beethoven's early Viennese compositions included many modest works: piano variations designed to showcase his own virtuosity, dances, songs for voice and piano, and chamber music, particularly for winds. Alongside such ephemera, Beethoven worked hard to master the large-scale genres of which he would eventually become the supreme exponent. By his mid-twenties, he had completed his Op. 1 Piano Trios, Op. 2 Piano Sonatas, Op. 5 Cello Sonatas, as well as his first two numbered Piano Concertos, Opp. 15 and 19 – the latter of which was revised multiple times, probably from an earlier work. Around this time, he also sketched a symphony but then abandoned it. Virtually all of these compositions are on a very ambitious scale – the Op. 1 trios average almost 1100 measures

each – and expanded the scope of the musical argument to the limit of Beethoven's models.

While Beethoven hit his compositional stride later than Mozart, he was by no means a late bloomer. By the age of 27, he was already a major success, and his reputation as a preeminent pianist and rising composer of great note was secure. In addition to the major works listed earlier, by 1798 he had written the Op. 9 String Trios (which he considered his best work until then), the three Op. 12 Violin Sonatas, eight or so more piano sonatas (including the famed 'Pathétique,' Op. 13), and had started on one string quartet of his Op. 18 series. His musical abilities allowed him to move rather freely in aristocratic circles, and he acquired a number of supporters from the nobility. Unlike earlier composers, for whom official patronage was necessary simply to earn a living, Beethoven was able to operate more or less autonomously as a creator and performer – which gave him greater freedom to compose the kind of music he liked.

In the midst of this success, Beethoven showed the first signs of hearing loss. His first mention of deafness dates back to June 1801, when he noted that 'for the last three years my hearing has become weaker and weaker.' The cause has never been conclusively determined. In any case, it took years for his hearing to deteriorate fully, and it was not until his early to mid-forties that he was virtually completely deaf. In that span, encroaching deafness played a major role in shaping the direction of Beethoven's life and career. Obviously, it made socializing with friends more difficult and romantic relationships even more so. His capacity as a pianist would gradually decline to the point where he could no longer give a public performance. In the famous Heiligenstadt Testament, a letter written on 6 October 1802, Beethoven revealed depths of despair verging on suicidal.

Fortunately, given the circumstances, one aspect of his life that did not deteriorate with his hearing was his ability to compose. In the interval between the onset of his hearing loss and the Heiligenstadt Testament, Beethoven's productivity had not diminished. He had completed a number of works on par with the finest compositions by Mozart and Haydn, including his first two symphonies, Opp. 21 and 36, the Third Piano Concerto, Op. 37, the six String Quartets, Op. 18, the ballet *Die Geschöpfe des Prometheus*, Op. 43, five more Violin Sonatas (up to those of Op. 30), more Piano Sonatas, up to Op. 31, plus a host of other major and minor works. Especially in his piano sonatas, by then numbering some 20 works, Beethoven had shown unprecedented audacity of formal experimentation. With Haydn's retirement around 1802, Beethoven was poised to become the preeminent composer of the new century.

Beethoven's Heroic Middle Period and the Transition to His Late Style

Shortly after the catharsis of Heiligenstadt Testament, works on an unprecedented scale began to appear – especially the Third Symphony, Op. 55, subtitled the 'Eroica' (Heroic) and originally dedicated to Napoleon, the 'Waldstein' Piano Sonata, Op. 53, and the 'Kreutzer' Violin Sonata, Op. 47. The time from about 1803 until about 1813 comprises Beethoven's

so-called 'middle period,' during which he was as great as any composer has ever been. Without exaggeration, this decade marks one of the most astonishing periods of sustained creative productivity in all of Western culture. In this span, despite steadily worsening hearing, bouts of ill health, and a rather tempestuous love life, Beethoven produced his Third through Eighth Symphonies, his last two Piano Concertos, Opp. 58 and 73, the Violin Concerto, Op. 61, five String Quartets, Opp. 59, 74, and 95, the first version of his opera 'Leonore' – later revised as 'Fidelio,' Op. 72 – plus a dozen or more masterly piano and chamber works, overtures, incidental music, and some of his finest songs.

While the middle period works opened up new vistas of extended thematic development and intense emotional expression, they built upon the forms and structures of the Classical style Beethoven inherited, rather than rejecting them. This is the case even when the novelty of Beethoven's style is most apparent – as in the enormous scale of the 'Eroica,' which is half again as long as any previous symphony; the famous four-note opening of the Fifth Symphony, Op. 67, whose development gives the work an unprecedented degree of thematic cohesion; and the programmatic depiction of nature in the Sixth ('Pastoral') Symphony, Op. 68, which is nonetheless expressed using standard musical syntax and forms.

Compared to the preceding decade, the years 1813 to 1817 were far less productive, both in quality and quantity. Beethoven wrote only one or two works a year that have since entered the regular repertoire, all on a smaller scale than their predecessors. Alongside these works are a host of ephemera, including Wellingtons Sieg, Op. 91, probably the most vacuous thing Beethoven ever wrote (though he was clear about its meretricious origins) and the bombastic cantata, *Der glorreiche Augenblick*, Op. 136. Throughout much of this time, Beethoven was caught up in legal proceedings to gain custody of his nephew Karl, which surely took away from his time and energy for composition. Meanwhile, his almost total deafness continued to isolate him from most of society.

However, like Beethoven's earlier compositional hiatus, the fallow season of his mid-forties presaged a major creative outburst. At a time when Vienna abounded with gossip that Beethoven was 'written out' and when Rossini's showy operatic music had replaced Beethoven in popular acclaim, he bided his time, studying the music of Renaissance and Baroque composers and groping toward a new style.

Beethoven's Late Period

The first works presaging Beethoven's new style were the two Cello Sonatas, Op. 102 (from 1815), and the Piano Sonata #28, Op. 101 (from 1816), which show an increased involvement with the contrapuntal and fugal treatment of musical material. Beethoven's late style arrived with a vengeance with the massive Piano Sonata #29, Op. 106, known as the 'Hammerklavier.' Written mostly in 1818, it takes 50 min to perform, twice that of even his greatest earlier piano sonatas. The Hammerklavier also has a textural roughness, structural complexity, and contrapuntal concentration far beyond any of his previous works. Beethoven justly considered this sonata to be his finest. Interestingly, months after sending it to the publisher, Beethoven

added a single introductory measure to the long slow movement, an indication of the care he took with the compositions he valued.

Though the Hammerklavier already embodied Beethoven's late style, it took some time for his absolute level of productivity to return to earlier levels. Preoccupied by plans for several major works, including what would become the *Missa Solemnis* and the Ninth Symphony, as of mid-1821 he had managed to complete only one additional significant composition, the Piano Sonata #30, Op. 109. By then, Beethoven's creative process had changed from sketching a main melodic line and only later filling in the other parts to one in which he wrote out numerous voices simultaneously in 'short score' – consistent with his renewed preoccupation with counterpoint and fugues.

By the start of 1822, Beethoven had again got into his stride, finishing what would be his transcendent final two Piano Sonatas, Opp. 110 and 111, the piano Bagatelles, Op. 119, and the Handelian Consecration of the House Overture, Op. 124. The year 1823 saw the completion of two of Beethoven's grandest achievements. One was the *Missa Solemnis* in D, Op. 123, a grand choral mass begun in 1818 or 1819. This was the most direct fruit of his study of earlier composers, and Beethoven himself regarded it as the greatest of all of his works. The second, for piano, was the 33 Variations on the Theme of Diabelli, Op. 120, which he started in 1819 as a relatively modest work. Four years later, it had evolved into an hour-long microcosm of Beethoven's art. Each bears comparison with only one other work in the entire history of music – respectively, Bach's B Minor Mass and Goldberg Variations. The other composition on which Beethoven labored intensively in 1823 and finished early in 1824 had no precedent in all of music history – the Ninth Symphony, Op. 125. In this work, substantially longer even than the *Eroica*, Beethoven introduced for the first time vocalists and a chorus into a symphony. Regarded by Beethoven as his greatest symphonic achievement, his setting of Schiller's 'Ode to Joy' in the finale remains one of his most popular melodies.

After the premiere of the *Ninth* on 7 May 1824, Beethoven focused his energies almost exclusively on the medium of the string quartet. The last quartets (Opp. 127, 130, 131, 132, 133, and 135) are often regarded as the greatest music ever written. In 1826, the last full year of his life, Beethoven's creativity remained at its height, despite the devastating suicide attempt of his ward and nephew Karl on 6 August. He completed the astonishing *Grosse Fuge*, Op. 133 – the most stylistically ahead-of-its-time work of his entire career. He also composed the String Quartet in C-sharp minor, Op. 131 – a work whose seven linked movements represent an unprecedented degree of formal experimentation, which Beethoven probably considered his greatest string quartet. In addition, he completed his enigmatic final quartet, Op. 135, and uncharacteristically wrote a new, more conventional finale for the String Quartet in B-flat major, Op. 130, replacing the *Grosse Fuge*.

The substitute finale was sent to the publisher on 22 November 1826. Around this time, Beethoven began to sketch a String Quintet, WoO 62. On December 4 or 5 he wrote the short canon *Wir irren allesamt*, WoO 198, his last composition. Shortly thereafter, he fell ill with dropsy and jaundice, was confined to bed for the last four months of his life, and endured several painful operations to reduce abdominal

swelling. Still eager to compose, he studied the works of Handel and promised the Philharmonic Society of London an apparently already-sketched symphony (the fabled Tenth) just eight days before his death. During a thunderstorm on the late afternoon of 26 March 1827, Beethoven raised a clenched fist, stared defiantly, and died. Three days later, more than ten thousand Viennese attended his funeral.

Beethoven's Position in Music History

Beethoven's position in music history is absolutely central, both in terms of eminence and the standard chronology. Among composers his reputation is unparalleled. Chronologically, Beethoven is almost exactly in the middle of the historical span comprising the standard classical repertoire. He assimilated much of the earlier music in the tradition he inherited, bringing unsurpassed technical mastery and experimentation to the intense expression of personal emotions, and in the process reaching one of the highest summits of that tradition. His impact on later composers, for over a century, was almost immeasurable. Today, beyond his eminence in music, Beethoven is a universal popular icon: his name, melodies, struggle with deafness, and even his unkempt hair are known to virtually every person in the world with access to print or other media.

Beethoven and the Study of Creativity

How Can Beethoven's Creativity Be Understood?

Ludwig van Beethoven is one of the most amazing creative personalities of all time. How can one explain his almost superhuman creative achievement? As he was the harbinger of Romanticism in Western music, it is tempting to view him as a Romantic or genius, denying that Beethoven's creativity can ever be meaningfully explained or understood. Indeed, the case of Beethoven provides as rich and difficult a challenge to creativity researchers as can be imagined. Without dismissing the question of Beethoven's creativity as unanswerable – or pretending to give a complete answer – I will use Beethoven to illustrate some themes of contemporary creativity research, as he is a particularly illuminating figure.

While Beethoven's creative achievement is unsurpassed, most of the particular factors that contributed to his achievement are not unique. Contemporary research has established the principle that creativity emerges from many factors interacting in complex, multiplicative ways. As some have noted, this yields the typical strongly positively skewed distribution of world-class creative achievement, with the vast majority of people huddled at the bottom, and a few outliers like Beethoven soaring far above them. So while there is no unitary explanation undergirding Beethoven's creativity, its constituents can be identified and understood.

A number of factors contribute to eminence in creative domains. Some of the most relevant presently are the existence of a rich symbolic tradition and socio-cultural milieu which a creator can enter, basic intelligence, the motivation to work hard and overcome adversity, the acquisition of a large body of domain-specific knowledge, the ability to approach a complex problem like musical composition in new and powerful ways,

the productive fluency to generate a large number of ideas, and the ability to judge and evaluate ideas as they are elaborated into finished works. Each is now discussed in turn.

External, Socio-Cultural Factors

Some of the factors influencing Beethoven's creativity lie outside Beethoven himself. Simply put, he was born in a time and place with an extremely well-established and valued musical tradition. The already-rich symbol system of Western music had developed throughout the eighteenth century, particularly among German-speaking composers. The socio-cultural infrastructure for patronage, performance, and publishing was also firmly in place. Beethoven's father was part of that milieu, and Beethoven himself was able to enter it at an early age.

Beethoven's progress through his socio-cultural system echoes that of many eminent creators. Prototypically born away from the main center of activity, they show early talent, are given initial tutelage, progress through a series of increasingly qualified teachers, and come to master their domain, though bristling somewhat at its restrictions. Ambitiously setting out to make a name for themselves, they then move to the geographical center of excellence in their domain, get to know the right people, after at least a decade of intensive work make a revolutionary breakthrough, and thereafter require another decade or so to make additional significant breakthroughs. Beethoven fits this profile quite well, in terms of his birth in Bonn, his early training, his move to Vienna, his networking among musicians and nobility, and the timing of his creative breakthroughs, namely, his first masterworks and the transitions to his middle and late periods.

A key point is the importance of luck and social contacts in facilitating creativity. For instance, his teacher Neefe likely introduced Beethoven to Haydn as the latter passed through Bonn, setting the stage for their Viennese association which helped launch Beethoven's compositional career. Beethoven was also lucky in receiving patronage and support from the nobility, even early on. This basic trajectory reinforces the importance of external, socio-cultural factors for a full accounting of creativity, particularly in getting to know other members of the field and taking advantage of opportunities when they arise.

Intelligence, Expertise Acquisition, and Motivation

Besides such external factors, Beethoven was clearly endowed with a number of personal characteristics that contributed to his creativity. I will focus on three inter-related factors: basic intellectual power, the acquisition of a vast domain-specific knowledge base, and the motivation to work extremely hard and overcome adversity.

Intelligence

Beethoven's basic intelligence was quite high. Estimates of his IQ give a figure around 150, putting him in about the upper one-thousandth of the population (though it should be noted that there is no reliable way of precisely estimating the IQ of deceased historical figures). While IQ and creative achievement appear to be correlated only up to around an IQ of around 120, many eminent historical personalities do appear to have had

very high IQs. Thus, while having a high IQ is no guarantee of being creative, it has been argued that a creative person with a high IQ should be able to accomplish more than a creative person with a lower IQ.

However, IQ is arguably a coarse measure of information processing. Other researchers have proposed other models of multiple intelligences. Of these, musical intelligence is clearly the most relevant to Beethoven. It has also been argued that it is not only one's primary intelligence that shapes a creator, but also the strengths and weaknesses among the other intelligences. Beethoven likely had strengths also in kinesthetic intelligence (e.g., in performing on the piano), intrapersonal intelligence (being adept at self-reflection), and to some extent, verbal intelligence (writing many high-quality letters). In contrast, his often rude manner and difficulty in maintaining social relations suggest a deficit in interpersonal intelligence; quantitative and visual-spatial intelligences are not salient either way.

Expertise acquisition and motivation

However Beethoven's basic intellectual capacity is conceptualized, it would have resulted in nothing without the willingness to channel his energy into the domain of music and work extremely hard at it, even in the face of major adversity, such as increasing deafness (In line with some conceptualizations of high ability, I include motivation as an intrinsic component of expertise acquisition). One vital basis of Beethoven's achievement was his early and continued acquisition in the domain of music. Numerous studies support the view that immense amounts of domain-specific knowledge are critically important for high-level performance and creativity. For instance, individual differences in conservatory-level music performance ability are largely attributable to the total amount of 'deliberate practice' engaged in. Similarly, even the greatest classical composers follow the so-called 'ten-year rule,' whereby even great creators require an apprenticeship of at least ten years of intensive immersion in a domain before producing original works of lasting value. Only three exceptions to the ten-year rule have been found, and each produced their first hit shortly before their tenth year of study.

In Beethoven's case, ten years is a conservative estimate. Rudimentary instruction started at the age of three or four; more rigorous training commenced around the age of eight, after he had already given a public performance; Beethoven began composing at the age of 11 or 12. However, his earliest works that are still regularly played were written only in his early twenties, and only by his mid-twenties did Beethoven begin producing masterworks on a fairly regular basis. Thus, almost 20 years elapsed between Beethoven's initial exposure to the domain of music and the production of the music that would establish his reputation. (Note, however, that this timeline is complicated by his teenage hiatus in composition.) These career landmarks are more or less on par with that of a sample of ten elite composers, including Beethoven.

Importantly, throughout his career, Beethoven continued to learn. Even though he was already composing masterworks in his twenties, he sought out teachers to develop areas that he felt needed work – such as vocal writing and the difficult medium of the string quartet. Later, especially to prepare for the *Missa Solemnis*, he combed libraries for old music and

treatises on liturgical procedures and immersed himself in the religious music of earlier composers – Palestrina, J. S. and C. P. E. Bach, and Handel.

Thus, throughout his entire career, Beethoven worked to develop an almost unparalleled depth of musical knowledge, probably among the highest in the world. This point is worth noting since a contentious issue in the study of creativity concerns the question of whether 'too much' knowledge can entrench a creator in an outmoded way of working and thus interfere with the production of original ideas. In principle, one can imagine an unknown pedantic contemporary having amassed more musical knowledge than Beethoven. Realistically, however, it is hard to think of another composer in Beethoven's time who had studied as much music – even beyond his own contributions expanding the domain itself. Also notable is Beethoven's idiosyncratic knowledge of Renaissance and Baroque styles of composition, which may represent a 'fruitful asynchrony' with his domain at that time.

Beethoven's Creative Process

Despite its importance, domain expertise is a necessary but not sufficient condition for creative achievement, and there are important differences between expertise, viewed as superior reproducible performance on well-defined problems, and the production of original works. Also important in Beethoven's case was his ability to improvise on the piano, indicating not just a mastery of familiar patterns, but also an ability to flexibly and readily deploy them in new combinations. This suggests some of the cognitive processes needed for meaningful creation. These include the ability to approach or represent a complex problem like musical composition in new and powerful ways, the productive fluency to generate a large number of ideas, and the ability to develop and evaluate ideas as they are elaborated into finished works. The first set of processes, on how to approach the problem of musical composition in general, guides ideation and elaboration in important ways. The latter two roughly map onto the two basic regimes of creative thought postulated by contemporary researchers: generating ideas and exploring their implications.

Beethoven's conceptualization of writing music

How did Beethoven conceptualize the problem of writing a piece of music? Interestingly, his approach differed from those of his predecessors and contemporaries in several key ways, beyond his deep, idiosyncratic knowledge base and acquired technical skill. Beethoven regarded art as an elevating force and the artist as attempting to raise mankind upward; thus, works could always be improved, and new works could surpass old ones to create a sense of progress. In line with this attitude, more than any previous composer, Beethoven was willing to rework musical material. He would routinely sketch many variations of a particular theme before selecting one to develop. Interestingly, while many of Beethoven's melodies are very famous, they are also among the least original in the standard repertoire. Thus, while Beethoven's emphasis was partly on generating musical ideas, he seemed more concerned about the potential for elaborating them – an emphasis consistent with the kinds of large-scale 'sonata form' works (like symphonies, piano sonatas, and string quartets) in which

he excelled. Finally, Beethoven also brought to his work extra-musical associations – literary, political, and nature-related – as well as a very strong moral element, in keeping with his ultra-serious sense of the purpose of art. This latter characteristic is most apparent in the exemplary moral message of his opera ‘Fidelio’ and his disparaging comments about the licentiousness of the texts (though not the music) of some of Mozart’s operas.

Idea generation and overall productivity

Beyond this, the origins of Beethoven’s ideas remain mysterious – a more general unresolved issue in the study of creativity. However, his fluency in combining patterns and generating ideas resonates with contemporary theories of chance conceptual combination. The basic capacity to generate ideas has traditionally been seen as a central aspect of creative thought. Indeed, from a historiometric perspective, the construct of creative potential is best approximated by simply examining total output, since great creators are almost always extraordinarily productive of ideas and works.

Consistent with this view, Beethoven’s productivity was quite high in absolute terms. In a recent tabulation of composer productivity, Beethoven was found to have written about 4902 minutes of original music (not counting arrangements or exercises). Over a career span of 45 years, this amounts to an average of 108.8 minutes of music per year – or a minute of music every few days, for almost half a century (though this is something of an underestimate, as it excludes drafts, does not account for orchestration, and includes unproductive years). When Beethoven’s annual productivity is tabulated (as can best be determined, given uncertainty in dating some of his works), his most productive period was between 1795 and 1806, during which he averaged about 216 minutes of music per year. His peak output occurred in 1795 and 1802, with 348 and 306 minutes of music, respectively. Thus, contrary to the stereotype of Beethoven painstakingly reworking his music over protracted durations, he was not invariably a slow worker and could write quickly when necessary: the 15-minute Sonata for Horn and Piano, Op. 17, was written allegedly in one day. Also, the overall career trajectory of Beethoven’s raw output resembles the inverted, backwards J-shaped age curve characteristic of many creators, with an added final upswing at the very end, reflecting the so-called ‘swan song’ phenomenon.

Creating masterworks: Elaboration and evaluation

An important part of Beethoven’s musical legacy was to raise the stakes for each major work; after him, the mass-production of historically earlier composers was simply not tenable. Perhaps partly because he traded quantity for quality, or because he was not hampered by official patronage, he also managed to produce a very high proportion of ‘great’ music. When masterworks are defined by a listing of works comprising the standard repertoire, some 67% of Beethoven’s music (measured by performance time) qualifies; a measure based on citations in a number of music history books yields a figure of 57%. This is far above any earlier composer, and only a few later composers have higher lifetime averages. Moreover, very importantly, Beethoven’s hit ratio (proportion of great music to total music, written in a given age interval) reliably increased over the course of his career, even when the analysis was restricted to the time after he had shown himself able to produce masterworks.

Such results suggest that Beethoven’s ability to judge the quality of his musical ideas and works was strong and likely improved with experience. Recent research has directly examined the question of the accuracy of Beethoven’s self-evaluations. Explicit self-criticisms of 70 compositions were found in Beethoven’s letters or conversations, spanning his whole career and most musical forms. Results showed that his positive or negative assessments were reliably associated with three posthumous citation measures of aesthetic success, and the likelihood of correct decisions strongly increased with age. Beethoven’s comments comparing several similar masterpieces were likewise largely consistent with expert ratings and recording counts. Finally, the ranking of works by listener-hours (number of complete recordings multiplied by performance duration) corresponded closely with his intra-genre preferences. The results suggest considerable self-critical acumen on Beethoven’s part, and they support a view of creativity in which knowledge and experience enable progressively greater creative accomplishments and sounder self-criticism.

Beethoven’s creative wisdom, coupled with the complexity and frustrations of his creative process evident from his sketchbooks, suggests a creative style that might seem self-contradictory. However, such characteristics have been consolidated into a particular type of creator, namely, experimental innovators, who are distinguished from conceptual innovators. Conceptual innovators show great certainty throughout the creative process, revise little, rebel against tradition, and typically produce their best work early in their careers. In contrast, experimental innovators struggle to create through trial and error, revise a lot, build on earlier traditions, and typically produce their best work late in their careers. While Beethoven made major musical innovations by his early to mid-thirties, as expected of a conceptual innovator, he also showed more characteristics prototypical of experimentalists, including creative processes marked by uncertainty and revision and a reliable increase in hit ratio and self-evaluation ability as he got older. Even at his most revolutionary, as in the transition to his middle period, Beethoven built on his and others’ earlier achievements, and a considerable continuity of style and musical concerns runs through his output.

Conclusion

Beethoven is as rich a case study for the investigation of creativity as one can imagine. Awe-inspiring as his creative achievement is, the psychological and social factors that made his creativity possible are not unique or exotic. Rather, it is their simultaneous combination in one person that is unusual. Moreover, available evidence supports the importance of considerable rationality in his creative process – witness his astute self-evaluation and capacity to improve his hit ratio with age. Beethoven’s ability to consolidate and develop the rich musical tradition he inherited, through the relatively novel means of a ruthlessly self-critical and revision-laden creative process, constitutes one of the most interesting studies in the history of human creativity. His success in harnessing the chaos of nascent ideas into an unprecedentedly coherent and expressive musical architecture, despite the burden of deafness, also gives strong cause for optimism in the creative potential of

humanity. No doubt Beethoven will be a touchstone for investigating the nature of creativity for as long as that enterprise persists.

Behavioral Approaches to Creativity

P D Stokes, Barnard College, Columbia University, New York, NY, USA

Glossary

Behavior What an individual does. What is done, and how often, depends on the consequences of the behavior.

Constraints Tools for (re)structuring problem spaces. Paired contingencies, one precluding (punishing) and the other promoting (reinforcing) search in separate, specific parts of the space.

Creative behavior Doing something that is new and useful, generative, or (at the highest levels) influential.

Problem spaces How problems are conceptualized by solvers. A problem space has three parts: an initial state, a goal state, and a search space in which to construct a

solution path. If all the parts are specified, the problem is well-structured. If not, it is ill-structured. Creativity is only possible in ill-structured problems.

Punisher A consequence that decreases the frequency of the behavior that produces it.

Reinforcer A consequence that increases the frequency of the behavior that produces it.

Solution by substitution Step-by-step restructuring of a problem space.

Variability How differently something is done. Creative behavior is associated with high variability.

Behavioral is a term associated with classic operant concepts. This article combines operant and problem-solving paradigms that share variation/selection processes and problems. Given creative behavior as a goal, a common problem is getting 'stuck' in successful (because they have been selected) behaviors. Solutions (variability and constraint selection) to this and other creativity problems are proposed.

Behavioral and Problem-Solving Paradigms

The basic behavioral model involves responding that is conditioned or learned. The content of the learning is a three way association between context, response, and consequence. The standard problem-solving model is an analogue with a more accessible vocabulary. This section focuses on parallels between the two paradigms.

Structural Similarities

Operants and operators

As shown in [Table 1](#), the shared structure has three parts: context, behavior, and consequence. In behavioral terms, this is an operant; in problem-solving terms, an operator.

With operants, the context is called a discriminative stimulus (S^d). In the presence of an S^d a particular response (R) leads to a predictable consequence. If the consequence increases the frequency of the response, it is called a reinforcer; if it decreases the frequency, it is called a punisher. Operators take the form of condition-action or 'If . . . then' rules. The context or condition is specified by the 'if,' the action by the 'then,' and the consequence, by the goal or sub-goal. Given a concrete example, the similarities should become clearer. Imagine then a driver approaching an intersection where the traffic light has just turned red. The discriminative stimulus/condition is the red light; the appropriate response/action is stopping the car; the consequence/goal

is not causing an accident. (This kind of consequence is known as a negative reinforcer: something bad (the accident) has been avoided.)

Response classes and default hierarchies

Both operants and operators are organized hierarchically: the most successful response or rule is found at the top. Low probability responses, including creative ones, appear after more likely, higher-in-the-hierarchy, responses. A response class is a set of operants, all of which lead to the same consequence. The response which has been reinforced most often occurs most often. A default hierarchy is a set of operators, all of which lead to the same goal or sub-goal. The default is the rule with the most general condition (which makes it the most successful); exception rules, which are lower in the hierarchy, have more specific conditions. Signaling the direction in which a driver is going to turn at an intersection provides an example here. Assuming that the car's directional signal is functional, the driver turns it on to blink left or right. This is the response that has been most successful most often in the past. It is the default rule. However, if the condition has changed (the blinker is malfunctioning), the driver can open the window and signal with his/her arm. This is the exception rule.

Functional Similarities

Variation and selection

Creativity in both paradigms depends on selection from a variable substrate. In Donald Campbell's operant model, 'blind' variants (arising via trial and error, chance, or accident) 'stumble' into the selection criterion. In Herbert Simon's problem-solving model, creativity involves specifying a novel goal criterion for an initially ill-structured problem. (An ill-structured problem is one in which all the information required for solution is not specified.) In Walter Reitman's and Patricia Stokes' versions, selection focuses on paired constraints that limit and direct search for a solution path.

Table 1 Comparison of behavioral and problem-solving structures and terminology

Models	Context	→ Behavior	→ Consequence
Behavioral	Discriminative stimulus	→ Response	→ Reinforcer or punisher
Problem-solving	If this condition	→ Then this action	→ Goal or sub-goal

In Mihaly Csikszentmihalyi’s model, the selectors (gatekeepers) rather than the selection criteria are specified.

Recombination and restructuring

Creativity occurs when responses/rules are reorganized in novel ways to meet and/or define selection criteria. In behavioral terms, responses are recombined; in problem-solving terms, problem spaces are restructured. This section considers recombination: restructuring is covered later.

Two things important to recombination are context and expertise. Context plays a pivotal part because responses activated at the same time are readily available for recombination. Expertise, in turn, enhances a domain-relevant repertoire: the larger the repertoire, the greater the number of combinatorial possibilities. Expert repertoires include skills (what the individual can do), and styles (what others have done). What-others-have-done become sources that the expert works with (adopts/adapts) or against (rejects/replaces).

Selection and recombination: still-life

To reiterate, available for selection and recombination are skilled and stylistic elements in the expert’s repertoire. The expert here is an unknown artist (Anonimo) who paints realistic still-lives. The context (which cues the artist’s responses) includes, at minimum, set-up (objects), medium (paints), and surface (canvas): the painter’s skill limits the ways in which the three can be manipulated. **Table 2** includes some of these: choosing and combining alternatives from each category (rather like a Chinese menu), the painter stretches a large, coarsely textured, rectangular canvas on which he draws a cartoon of three objects lined up, close-up, and at eye level. **Table 2** also includes two well-known painters whose styles strongly influence his. A cartoon-version of his painting, rigid in composition, but riotous in color, is presented in **Figure 1**.

Selection as Problem

While the above analysis can identify combinations specific to an artist’s style, it cannot tell us how or why they were selected: this is the criteria problem. It is one of three associated with selection. The other two are related to variability.

- **Problem one.** The criteria problem: identifying how and why elements are selected and combined.
- **Problem two.** The variability per se problem: while creativity requires variability, selection reduces it.
- **Problem three.** The successful solution problem: since selected (rewarded) responses increase in frequency, experts get stuck in successful solutions.

Table 2 Combinations in still-life painting

Context	Giorgio Morandi	Wayne Thiebaud	Anonimo
Objects			
Arrangement	In a row	In rows	In a row
Distance	Mid-distance	Mid-distance	Close-up
Viewpoint	Above	Above	Eye-level
Canvas			
Surface	Smooth	Smooth	Rough
Shape	Rectangular	Rectangular	Rectangular
Size	Small	Mid-size	Large
Paint			
Hue	Monochromatic, local	Multiple, expressive	Multiple, decorative
Intensity	Muted, mixed	Bright, mixed	Bright, primary
Value	Low-contrast	High-contrast	High-contrast
Outlines	Blurred	Multipled	Sharp-edged

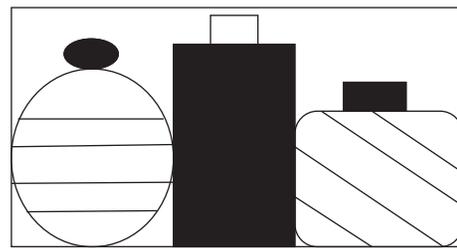

Figure 1 Cartoon version of still-life. (The hues are blue, green, black (shown) and yellow. Imagine that the stripes on the outside bottles are cadmium green; the bodies, ultramarine blue. The middle bottle is black; its cap is ultramarine. The negative space (background) is cadmium yellow.) The drawing was created by the author.

Solutions to the problems are suggested by the variability and problem solving literatures.

Selection as Solution

Selecting Variability Levels

Habitual variability levels

Variability, like other aspects of behavior, is the product of reinforcement history. Levels (high or low) associated with early success (in specific domains) are selectively maintained aspects of skilled responding. Put another way, learning how to do something includes learning how differently to do it. The *how* is the skill; the *how differently* is the habitual variability level, an individual’s preferred performance range in which responses differ from each other. Note that these are the two things (expertise and variability) on which creativity depends.

Importantly, while skills remain malleable (repertoires can be expanded and performance perfected over time), habitual levels do not. Pressure to regain a habitual level arises from the discomfort of either anxiety or boredom: the former when variability requirements are too high; the latter, when they are too low. If boredom or anxiety motivates an individual to regain a habitual level, then variability shifts due to changed contingencies should be – and are – transitory. For example,

variability increases temporarily when new strategies are acquired by children, when novel contingencies are encountered late in training by college students, when novice-to-expert transitions occur in adults. After the new contingency is mastered, variability returns to its 'normal' level.

Training

Protocols known to establish high habitual levels include variability practice, difficult discriminations, and incomplete instructions. In these protocols, early tasks are difficult enough to require trying many things, but not so difficult that high variability is punished rather than rewarded. Compared to their opposites (consistent practice, easy discriminations and complete instructions), acquisition appears less effective (more errors are made, more time is taken), but retention and transfer are superior (high variability facilitates further learning as well as transfer by directing attention to contingency changes). Lag and frequency-dependent schedules function in similar manner. Lags specify the number of prior responses from which a current response must differ. For example, in a computer maze game, college students and fifth, but not first, graders easily master lags of ten. This means that points only accrue for paths through the maze that differ from ten prior paths (the most efficient strategy in this case is to adapt a visual algorithm in which every path shifts in a systematic fashion). Frequency-dependent schedules target less probable/frequent responses for reinforcement. In both cases, whether the effects are short-lived or lasting depends on how early in training each schedule is encountered.

Selecting Constraints

Constraints are search tools; their objects are solution paths in problem spaces. Both are discussed, problem spaces first.

Problem spaces

A problem space is how a problem is conceived by its solver. It has three parts: an initial state, a goal state, and a search space for constructing a solution path between the two. If the problem is well-structured, all parts of the space, including a goal criterion, are specified: the result is a predictable, correct solution. Creativity is only possible with ill-structured problems, which are specified sequentially and strategically. Sequentially means constraint pair by constraint pair; strategically, that the pairs are selected to clarify and satisfy the novel goal criterion.

Constraints

In problem-solving parlance, constraints come in twos: one precludes or limits search in some parts of the problem space, while the other promotes or directs search in other parts. In general, creativity rests on precluding (in operant terms, punishing) reliable, predictable responses, and promoting (reinforcing) novel, unexpected ones. This is, of course, too general to be useful. 'New' is not enough. The to-be-precluded must be particularized, so too its substitute. Thus the focus should be on selecting specific things to preclude (work against) and others to promote (work with) in their places.

Creativity involves four constraint pairings that identify what the individual works with and against. What you work with substitutes for, replaces, what you work against. The four

pairs are source constraints (elements for recombination), goal constraints (overall stylistic criteria), subject constraints (motif or content), and task constraints (materials and their application). An accepted, well-defined style (alternatives to style (applicable to the arts) are model or paradigm (for the sciences)) is typically the initial state of a creativity problem; a novel style with a not-yet-defined criterion is the goal state. **Table 3** simplifies the parts of a creativity problem: subject and task constraint pairs are located in the search space. The initial (the to be precluded style) and the goal (the to be promoted style) states are the pairs that constitute the goal constraint.

Solution by substitution I: drama

Thornton Wilder acknowledged the role of constraints in creativity. 'Form is accepted limitation' is how the playwright put it. **Table 4** presents a small set of Wilder's 'limitations.' The well-defined problem to be restructured was realist drama: its defining characteristics are delineated in the preclude column. Two of its well-known dramatists are Ibsen and Chekhov.

Wilder's initial substitution (abstraction/allegory in place of realism) precipitated, indeed necessitated, the source, subject, and task constraints that followed. Precluding contemporary, realist sources promoted abstract, classical ones: Greek tragedy (the narrator replaces the commenting chorus), Commedia (bare stage, stock characters, pantomime), and Noh (telescoping of time). In *Our Town*, subject and task constraints cascade from a specific abstract/allegorical goal: revealing "the cosmic in the commonplace." The commonplace is the human condition, its unchanging (timeless) cyclical events (the typical) unnoticed (in their particulars) and undervalued (by the

Table 3 Parts of a creativity problem

<i>Initial state</i>	<i>Existing style</i>
Search space	Subject and task constraint pairs Preclude specific elements of the initial state → Promote substitutions
Goal state	Novel style

Table 4 Constraints for Wilder

<i>Category</i>	<i>Constraint pairings</i>
Goal	Preclude realism → Promote abstraction/allegory
Subject	Preclude the particular/limited → Promote the typical/timeless
Task	Preclude climatic form ^a → Promote episodic, didactic form
	Preclude linearity → Promote rearrangement of time
	Preclude illusion, representation → Promote theatricality, presentation

^aClimatic form is linear, multiple pasts to converge at one critical point (the climax) in the present.

living). There is a lesson to be learned, thus the omniscient narrator (informing us of future events, commenting on past and present ones), and the episodic form (focusing, forcing, our attention). (Notice how the pairs produce operators: If the task involves form, then (preclude the climatic and) promote the episodic. Typically, only the promote parts are specified, thus the parentheses.)

Solution by substitution II: art

Max Beckmann’s painting is also mythic and didactic. Its goal was secular: redemption through art. “Autonomy in the face of eternity” is how the artist put it. Redemption precluded realism, identifying features of which appear in the preclude column of Table 5. Substitutions restructured the problem space for realistic painting.

The new mythology was signaled by, cloaked in, symbols of the old. Its sources are sacred (triptych altarpieces; graphic distortions (a good example is Gruenwald’s Isenheim altarpiece); color-saturated, black-outlined, stained glass). Up close, its images (distorted, compressed) are disquieting; from a distance, their saturated colors seduce, their enigmatic figures mystify. Myth requires repetition: a story is told and retold, its variations are recognizable because its elements are limited. Beckmann’s protagonists (king, bellhop, young man, woman), settings (stage, studio, bar) and props (fish, sword, phonograph) appear and re-appear, iconic, ritualistic remnants of the religious.

There are three parallels with Thornton Wilder: first, Beckmann’s pairings (like Wilder’s) are easily interpreted as operators: *if* selecting form, *then* (preclude single panel and) promote/use triptychs; second, Beckmann’s initial substitution (art for religion) directed, dictated, the selection of each subsequent pairing; finally, the scope of Beckmann’s sources, his expertise, like Wilder’s, was encyclopedic.

Summary Conclusion

I conclude by summarizing my proposed solutions to the three problems inherent in selectionist models of creativity. Notice that both are behavioral in the most basic sense, that is, success depends on consequence.

Selecting Variability

If high habitual variability levels are acquired early in skill acquisition, then individual creators will be motivated to

Table 5 Constraints for Beckmann

Category	Constraint pairings
Goal	Preclude redemption through religion → Promote redemption through art
Subject	Preclude the realistic → Promote the mythic
Task	Preclude single panel → Promote triptych
	Preclude naturalism in space, shape, and color → Promote compression, distortion, and saturated, expressive color
	Preclude the individual → Promote the type
	Preclude the obvious → Promote the enigmatic

maintain them. This addresses both problem two (selection reduces variability, unless variability *per se* is selected) and problem three (most experts get stuck in successful solutions, those with high variability levels do not).

Selecting Constraints

Solution by substitution addresses problem one (how and why are elements selected and combined). *How* involves constraint pairs: precluding (punishing) and promoting (reinforcing) specific elements (subject and task constraints) in a to-be-restructured problem space. *Why* involves goal criteria: to be precluded is a currently accepted/successful goal criterion (the initial state) (this is often an artist’s own style: in masters like Monet and Matisse at least three major stylistic shifts occur in a creative career); to be promoted is its not yet specified substitute (the goal state). Subject and task constraints are then strategically selected to specify and realize the new goal. Source constraints provide candidates for the substitution process, which proceeds incrementally, constraint pair by constraint pair.

Returning to our earlier still-life example, the initial state might have been Morandi’s (traditional) or Thiebaud’s (painterly-Pop) style (images of both artists’ painting are easily accessible on Google Images). To replace either, and remain recognizable as still-life, Anonimo’s goal criterion could be characterized as exaggeration. (An alternative would be pattern-making. This would be more convincing if the background were also stripped, vertically). This would be *why* he enlarged the objects, expanded the canvas, painted in primaries. *How* is simple to surmise: select specific elements of existing still-lives (mid-distance, small surface, mixed colors) and their substitutes (close-up, large surface, primary colors).

Concluding Caveat

The preceding ‘solutions’ may seem, to some readers, simple (they are, like all behavioral models, consequential), to others, prosaic (they are, like all problem-solving models, incremental). The caveat is that creativity at the highest levels (at the lowest level, a creative response is appropriate or useful; at the highest, it is influential, altering its domain; in the mid-range, it is generative) depends critically on encyclopedic, domain-based, expertise (look back at Wilder and Beckmann) and high habitual variability levels in the domain of expertise. In this, the gifted are advantaged beyond and by their gifts, which – by accelerating skill acquisition – produce both high variability and expansive repertoires.

Alexander Graham Bell 1847–1922

Inventor of the telephone

M E Gorman, University of Virginia, Charlottesville, VA, USA

This article is reproduced from the previous edition, volume 1, pp. 185–189, © 1999, Elsevier Inc.

ALEXANDER GRAHAM BELL was an inventor best known for the telephone. He was also an accomplished teacher of the deaf who married one of his pupils, Mabel Hubbard. Bell started on his invention career at the age of 11, with a device to remove the husks from wheat. But his major accomplishments were as a telegraph inventor. Initially, he focused on a new form of multiple telegraph, but by 1875 he was working on a device that would produce both speech and musical signals, which he patented in 1876. He spent most of the next decade defending this patent in court; it became the basis for the Bell Telephone Corporation, whose stock made Bell a millionaire. He worked on a variety of other inventions after the telephone, including airplanes, speedboats, phonograph records, and kites, but never again made a breakthrough to equal the telephone. Bell continued to play an active role in teaching the deaf, and also became president of the National Geographic Society and a regent of the Smithsonian.

A portrait of Alexander Graham Bell taken in later life (American Telephone & Telegraph Co.).

Background

Bell was born in Edinburgh, Scotland, in 1847. His grandfather was a teacher of elocution and his father had continued in this business, developing a form of visible speech. Bell and his brothers were trained in this visible speech and gave demonstrations in which their father would write down a sound made by a member of the audience, and the Bell brothers would enter the room and reproduce it. Bell's father also encouraged the brothers to build a model of the human vocal chords. From his family, Bell acquired expertise in speech and audition. In 1866, he became interested in Helmholtz's apparatus for reproducing vowel sounds electromechanically. Bell came to

believe that this device could transmit vowel sounds electronically, a creative error that spurred him to think about using tuning forks to send multiple, distinct tones over the same wire, creating a harmonic multiple telegraph. Unfortunately, Bell's brother, Alexander Melville, died of tuberculosis in 1870. In order to preserve the health of their remaining son, the Bell family moved to Canada that same year. Bell eventually became Professor of Elocution at Boston University in 1873. He continued to experiment with multiple telegraphy, and in 1874 became aware that at least one other inventor was doing very similar work: Elisha Gray. These two inventors each thought the other was stealing his ideas, because their telegraph devices were based on the idea of sending multiple tones over the same wire.

The Telephone

In 1875, Gardiner Hubbard and Thomas Sanders provided funding for an assistant, Tom Watson. On June 2, 1875, while Bell and Watson were trying to transmit multiple distinct tones over a single wire, one of the steel reeds got stuck and when Watson plucked it to free it, Bell heard clearly in the other room a composite tone. He instantly saw that this single reed could be used to transmit speech. This act of serendipity was made possible by Bell's unique background and experience; he alone saw the potential in what for most inventors would have been an annoying error. Bell had Watson construct the first telephone that night. Unfortunately, it did not work very well, but Bell was convinced he had the principle on which speech and telegraphic transmission would be based, and he began to write a patent. The application was filed by Gardiner Hubbard on February 14, 1876.

On the same day, a few hours later, Elisha Gray showed up at the patent office with a caveat for a speaking telegraph. (An inventor could file a caveat to signal his intention to complete an invention and file a formal patent at a future date.) Bell's patent focused on the form of current one would have to use to transmit speech; Gray's caveat focused on a transmitter that used liquid as a medium of variable resistance. Bell's mental model for his device was the human ear; Gray's was a string telephone. The patent and the caveat were thrown into interference, but based on the fact that his patent came in earlier, Bell was awarded a patent on March 7th, 1876.

He did not succeed in transmitting speech until a few days later, and to do it, he used a device that bore a superficial resemblance to Gray's liquid transmitter. This has led to speculation that Bell somehow stole the telephone idea from Gray. Bell did learn from an examiner that his interference with Gray concerned the use of liquid as a resistance medium, and that

may have encouraged Bell to do more experimenting with liquids. In the end, he returned to devices that used a heavy metal diaphragm to induce or alter a fluctuating current in an electromagnet without any intervening resistance medium. It was left for other inventors like Thomas Edison to perfect a superior form of transmitter based on the use of carbon as a resistance medium. Bell spent much of the succeeding decade in court, defending his patent for the fledgling Bell Corporation. He married the daughter of his principal backer, Gardiner Hubbard, on July 11, 1876. She had been one of his deaf pupils. The stock the couple held in the growing Bell Corporation made them both wealthy, even after Bell retired from the company in 1879.

Other Inventions

Bell continued to invent for the rest of his life, although he never scored another success on a level with the telephone. He sought to repeat his earlier success with a device called the photophone, in which light was translated into electricity. He hired another assistant and replicated the kind of intense experimenting that led to the telephone, even experiencing a moment of joy similar to the first transmission of speech. In the former case, Bell uttered the famous words, "Watson, come here, I want you"; in the latter, Bell's new assistant Tainter sent Bell a message to come to a window and wave his hat, and Bell reported doing so with vigor. Bell hoped the photophone would surpass Edison's carbon transmitter: it required no wires, and could be said to anticipate fiber optics. However, the ease with which a beam of light could be interrupted consigned this device to obscurity, even though Bell thought of it as his greatest invention.

When he was awarded the prestigious Volta Prize in 1880 for his invention of the telephone, Bell invested the money in a laboratory to continue the photophone work. But he wanted a project that would pay, and he saw an opportunity to leapfrog his rival Edison, whose phonograph was still a prototype poorly suited to commercial use much like Bell's early telephones. It was Bell's assistants who developed and patented an improved method for engraving phonograph recordings in 1886; Bell had become increasingly distant from the actual research. Bell put his share of profits from the successful invention into a trust fund for research on the deaf. When James A. Garfield was shot, Bell tried to develop a device that would detect the bullet, but it failed because the bullet was too deep. However, his telephonic bullet probe was used by others in the days before x-rays and even after, when x-rays were inconclusive. Bell also invented a crude form of iron lung.

In the 1890s he experimented with flying machines, trying an analogy to his earlier telephone work. If a heavy metal diaphragm was, paradoxically, the most sensitive membrane for a telephone, why not experiment with heavy flying machines? Bell initially teamed up with Samuel Langley, secretary of the Smithsonian. Langley flew a model, but failed with a full-sized airplane. Bell's own interest in flight turned to kites, and his wife Mabel helped him find another Watson: Casey Baldwin. Out of this collaboration came an idea ahead of its time: using tetrahedral supports in construction, Bell founded an Aerial Experiment Association that included himself, Baldwin, and Glenn Curtiss. Bell was one of the independent discoverers of the idea of using ailerons and his group built and flew several successful planes before breaking up.

By now, Bell had settled at Beinn Breagh, an estate he purchased in Canada. Bell and Baldwin also worked on hydrofoils, translating Bell's principle of heavy diaphragm for the telephone and heavier-than-air flying machine into heavier-than-water speedboats. The work was briefly suspended during World War I, because Bell did not want to pursue research with naval implications in a neutral country, but was renewed when the United States entered the war. Bell's final hydrofoil design set a world record in 1919, but by then, the Navy no longer had any interest. Bell also conducted experiments in an effort to breed multinippled sheep.

Teacher and Mentor

Bell was not only an inventor. He continued his important work in teaching the deaf, and he also encouraged creative intellectual work by others. He took over as president of the National Geographic Society during a time when the Society was flagging and hired Gilbert Grosvenor, an energetic young editor who realized Bell's vision for a more popular, accessible magazine and a membership in the thousands. Bell also served as regent of the Smithsonian and used his own money to provide resources for geniuses like Charles Peirce. Bell was a collaborator in his own work and encouraged others in theirs—even competitors like the Wright brothers, whose success he greeted with enthusiasm. Bell died at his beloved Beinn Breagh on August 2nd, 1922, with Mabel holding his hand.

Glossary

Bipolar mood disorders A group of related mood disorders described in the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*, 4th edition, Text Revision (DSM-IV-TR). These can be serious, but they are also often effectively treated. Bipolar disorders are characterized by the presence of an episode of unusually elevated mood, but they typically also involve episodes of depression; these episodes of high and low mood frequently alternate with periods of normal mood. Several types of bipolar mood disorders can be distinguished. Bipolar disorder (sometimes termed bipolar I disorder), formerly termed manic-depressive disorder, is defined by a history of one or more episodes of mania – a severe mood elevation that can be euphoric or irritable but causes serious adverse consequences for an individual, such as becoming psychotic, having to be hospitalized, or experiencing severe occupational or social impairments. Hypomania involves an unusually expansive or irritable mood but is milder than mania. Bipolar II disorder involves episodes of severe depressions, along with one or more episodes of hypomania. Cyclothymia is a chronic disorder in which the person experiences many episodes with hypomanic symptoms, as well other episodes with depressive symptoms that are less severe than in bipolar I or II disorders. Bipolar disorders run in families. A familial liability to bipolar disorder is manifested in a wide range of psychiatric syndromes, from mild to severe. Liability is manifested more frequently as depression than mania. A person who carries liability may not even experience symptoms (although subclinical manifestations, including mood elevations, have been postulated).

Compensatory advantage A biological model of inherited disorders for which a psychological parallel has been suggested. In biology, there are inherited liabilities that run in families and not only increase vulnerability to illness, but are also tied to positive characteristics that run in the same families. An example is sickle cell anemia, a recessive genetic disorder in which individuals who inherit a copy of a mutant gene from both parents experience serious, often fatal, medical complications. However, individuals who inherit only one copy of the mutant gene usually have relatively mild symptoms, and these carriers of the gene gain an important compensatory advantage: resistance to malaria. A compensatory advantage involving enhanced everyday creativity has been suggested in connection with genetic liability for bipolar disorder.

Eminent creativity This term applies to outstanding creators or creative accomplishments where recognition has been given by society or by relevant professional organizations in forms such as prizes, awards, honors, or publication. The quality of originality or novelty is generally part of what is recognized. Eminently creative individuals and their accomplishments are thought to have exceptional qualities or importance in their cultural context.

Everyday creativity This term applies to creators or creative accomplishments that involve day-to-day activities at work or leisure and are characterized by both originality (involving new and unusual aspects) and meaningfulness to others (rather than being completely random or idiosyncratic). Many types of activities qualify, and they can be concrete products, behaviors, or ideas. The creativity has more to do with how a task is done than what it is called. Thus while the painting of a scene would typically involve significant creativity, it may not if it simply involves following 'paint-by-number' instructions. Everyday creativity can be expressed in a variety of activities, including, for example, making home repairs, designing children's activities, reorganizing an office, counselling a friend, doing gourmet cooking, or charitable work – so long as the activities involve significant originality and are meaningful or adaptive.

Inverted-U effect This phenomenon refers to a curvilinear relationship between two variables, in which both high and low levels of a predictor variable are associated with lower levels of the outcome variable, whereas an intermediate level of the predictor variable is associated with the highest, or optimal, level of the outcome variable. Some research suggests that certain psychological characteristics related to bipolar liability, when they are neither too strong nor too weak, may be associated with higher creativity, showing an inverted-U relation between bipolar liability and creativity.

Unipolar mood disorders Unipolar disorders are characterized primarily by periods of unusually low mood, usually alternating with periods of relatively normal mood. Adverse effects of depressed mood on other psychological functions are also typically present, such as disturbances in sleep, appetite, and energy. These mood disorders can range from major or severe depressions to milder ones, and these milder forms can sometimes take the form of more pervasive or long-lasting dysthymias that involve dysphoric mood. These disorders can be extremely serious, but effective treatments for them are often available.

Introduction

Throughout history, one finds the notion of a link between creativity and psychopathology, going back to pre-Grecian myth and Plato's divine madness. As will be discussed, there is scientific support from recent research for this long-standing belief in an association between increased creativity and psychological disturbance. Particularly among eminent creators in the arts, there are very high rates of major mood disorders, both bipolar and unipolar. This evidence from recent research fits with the findings of older studies. Among eminent creators in nonartistic fields, however, the patterns of relationships involving mood disorders are more complex.

In studying everyday creators, researchers have tended to start with samples of subjects chosen for clinical reasons rather than their creativity. This is a key difference from the research design used in studies of eminent creators, as will be discussed. Research evidence to date also supports the presence of a significant advantage for everyday creativity – for originality in everyday life – in individuals with a personal or family history of bipolar disorders. The most creative individuals may not themselves be the most severely disordered, in accordance with an inverted-U hypothesis of the relation between creativity and liability for bipolar disorder. The most creative person in a family with bipolar disorder may often be one who is psychiatrically normal. In the latter case, what may be important is not the presence of psychiatric symptoms in a particularly creative person, but rather some positive and subclinical psychological traits that run in the families of people with bipolar disorder.

Research findings suggest the optimistic view that a creative advantage associated with liability for bipolar disorder is not directly linked to the pain and suffering that can accompany mood disorders, but rather to a more positive psychological factor. Moreover, some research raises the question of whether there are creative advantages that, in themselves, may heal or even protect against development of full-blown mood disorders. Further work on this issue is needed. These issues are important because of the sheer numbers of people affected by mood disorders. By some estimates, as much as 4–5% of people in the general population may end up developing a 'bipolar spectrum disorder,' ranging from rather mild to quite severe in degree. If each affected person has even one nonmood-disordered relative carrying a familial risk, as much as 10% of the population could have a heightened potential for everyday creativity and its benefits.

Finally, a note of caution is in order. We are discussing some serious and painful mood disorders, including major depressions and bipolar disorder. It is important not to romanticize these disorders just because creativity might at times be involved. The problems associated with these disorders are severe and often life-threatening. Without treatment, roughly one out of five people with a bipolar disorder will end up taking his or her life. This outcome is particularly tragic, given that treatment can often be highly effective. Furthermore, it appears that treatment may often increase creative potential and achievement. Treatment options should be carefully investigated by anyone who has, or is at risk for, a mood disorder.

Spectra of Mood Disorders

Mood swings appear to fall along a broad continuum of severity. At some level, they may even affect many people in the population at large, as found in one clinical study in which 40% of the control group showed cyclical mood swings that were milder but similar in periodicity to those of a clinical sample. Another major study found that during colder months of the year a great many people suffer at least a few minor symptoms of winter blues or seasonal affective disorder.

Traditionally, there are two broad classes of mood disorders: major depression and bipolar disorder, estimated by some studies to affect roughly 5–10 and 1% of the population, respectively. Even here, though, there are further spectra, which range into milder variants. The underlying risk for mood disorders displays a strong genetic influence, as shown by the results of adoption and twin studies. However, there is also a large (but poorly understood) environmental component. Bipolar risk or liability involves a more marked genetic component than does risk for unipolar depression. The strong tendency for bipolar mood disorders to run in families is illustrated by one study of over 500 relatives of bipolar disordered (manic-depressive) individuals, in which over 23% of the relatives had a major mood disorder. Even though these relatives were chosen because they had a family member with bipolar disorder, over half of all the mood disorders in these relatives were unipolar depression rather than bipolar disorders. Do these depressed relatives also carry some advantage?

In fact, research suggests implications for enhanced creativity in the relatives of persons with bipolar disorders, even including the psychiatrically normal as well as the unipolar depressed relatives of people with bipolar disorders. Hence, it is important to consider both personal and family psychiatric history.

In defining mood disorders, one should note that there are many more features required for diagnosis than the few given here; these features are listed in the *Diagnostic and Statistical Manual*, 4th edition, *Text Revision (DSM-IV-TR)*, of the American Psychiatric Association. In a family at risk for bipolar disorder, depressive manifestations can range from dysthymias and milder depressions to severe major unipolar depressions (all of these can occur without a history of clinically significant periods of mood elevation). As noted in the glossary, there are bipolar disorders of varying severity. These include bipolar I disorder, bipolar II disorder (which involves milder mood elevations alternating with episodes of severe depression), and cyclothymia (which involves milder mood swings that may be rapidly alternating). Especially in bipolar I and II disorders, there may be long periods of normal mood between such mood swings. A smaller number of individuals in families with a history of bipolar disorder may show 'schizoaffective' disorders, which are characterized by the presence of psychotic features, such as hallucinations and delusions, that occur when the person is experiencing episodes of mania or depression. Thus a bipolar liability can be manifested in a variety of ways.

The course of mood disorders can also vary dramatically, in both quality and quantity. For example, some people may have only one episode of depression in their whole life, whereas

others may experience dozens of depressive episodes. In addition, some people with mood swings may also spend a great deal of their time in a state of relative euthymia, or normal mood. Thus, most individuals with mood disorders do not have an ongoing chronic and unchanging depressed or manic state – a factor that may be important to creativity. Both temporary psychological state factors and ongoing trait factors may be significant.

Bipolar–Unipolar Disorder Distinctions

At this time, research is more plentiful on creativity in families with bipolar compared to unipolar disorders. It is worth repeating that pure unipolar depression is an even more common outcome in individuals with a bipolar family history than are bipolar mood swings, and that such depression may also predict for creativity. One preliminary study suggests, for example, that creativity may be higher in depressed patients with bipolar disorder in their family than in depressed patients without this family history. Perhaps there are subtle and subclinical factors operating – even ones that are adaptive and positive – beyond the more debilitating symptoms. This issue needs careful study. Clinicians can be so intent on sniffing out psychiatric illness and dysfunction that they fail to notice when something is going right, such as unusual creativity.

The several sections that follow concern issues of (a) eminent creativity and mood disorders; (b) everyday creativity and mood disorders; (c) mood disorders, creativity and evolution; (d) biological models in which illness and health may be intertwined; and (e) conclusions and recommendations.

Eminent Creativity and Mood Disorders: Considerations

There is evidence for an association between creativity and bipolar disorders, but the answer depends upon the way the question is asked.

Defining Creativity, Defining the Question

People often identify creative outcomes using a minimum of two criteria involving (a) originality and (b) meaningfulness to others (as opposed to randomness or idiosyncrasy). With eminent creativity, there is the additional criterion of social recognition of the creative activity – the achievements and their creator have been recognized and won acclaim, either from society at large or from people in particular fields or subpopulations. Many think of creativity largely in terms of people with eminent accomplishments – for example, the novels of the best-selling authors, the discoveries of Nobel prize-winning scientists, or paintings that went for millions at an auction. Such creators, or creativity, should have some different ingredients from those associated with everyday creativity.

A critical caution: the question one asks helps determine the answer. The results of research depend on whether one is studying (a) eminent versus everyday creators; (b) people chosen for mood disorders rather than their creativity (the second can be an overall better-functioning group); (c) patterns across families versus within individuals (in families one can find examples of both unusual creativity and mood disorders,

though not necessarily in the same person); or (d) a particular field of endeavour (e.g., the arts versus the sciences).

Are the Rumors About Artists True?

Several modern studies of artistic creativity and mood disorders are notable because they provided more solid support to a range of older and less rigorous studies that pointed in the same direction. For example, in Nancy Andreasen's study of 30 well-known creative writers who were teaching at the renowned Iowa Writers Workshop, a remarkable 80% had a history of a major mood disorder (compared to 30% of controls). In addition, over half of those affected had a form of bipolar disorder, and a little over half of that number had a history of a bipolar II disorder, showing milder mood elevations.

Supportive evidence was obtained by Kay Jamison, who asked 47 highly distinguished British artists and writers if they had been treated for a psychiatric disorder. A full 38% said that they had been so treated, with mood disorders again highly prominent. These percentages are almost certainly underestimates of the rates of mood disorders in these eminent creators, because only about one out of three mood-disordered persons currently tends to seek help at all (a particularly sad fact, given the efficacy of treatment). Furthermore, a full 89% of these eminent persons had had intense creative episodes (of a modal length of two weeks), which showed many of the symptoms of clinical hypomania. Finally, these rates may be compared to the lifetime prevalences of bipolar and unipolar disorders in the population at large, which are substantially lower, in the range of 1 and 5–10%, respectively.

Further support comes from Arnold Ludwig's psychobiographical study of more than 1000 deceased figures whose biographies were reviewed in the *New York Times Book Review* and covered 18 different professional fields. Almost two-thirds of the poets had had bouts of depression, with rates of depression for expository and fiction writers, visual artists, and musical composers in the 40–50% range. Mania occurred in as much as 13% of poets before age 40, and 5–10% of several other artistic groups. Moreover, these eminent creators may have had an even higher rate of more subtle bipolar spectrum disorders, including clinical hypomania and bipolar II disorder, which could not be differentiated by this study's particular biographical and diagnostic methods.

These results support findings from a range of older studies' findings from the nineteenth century to the early twentieth century, which also indicated a creativity–psychopathology connection, particularly in the arts, where most of the work had been done. Despite varied research design flaws, these older studies tended to point in the same direction, supporting a connection between artistic creativity and psychopathology, particularly mood disorders.

A Different Story for Scientists?

An older study that included scientists showed them to be a healthier group than artists on average, with nonpsychotic disorders only about half as common as in artists. More modern research supports this conclusion, including Ludwig's finding that across 18 occupational groups, there was a much

healthier picture for nonartists than for artists – or else, the mental illness in scientists was less obvious or less likely to be reported. Social scientists showed rates of depression in the mid-20% range, and physical scientists showed rates in the low teens. Other groups showing lower rates of psychopathology included businesspersons, explorers, athletes, military figures, and social activists.

More subtle bipolar disorders and family history were not assessed. Still, where overt mood disorders are concerned, the best predictor is not being an eminent creative person but, rather, an eminent creative artist. Note, however, that there are many mood-disordered people who do not become eminent, or even highly creative. What other factors might combine to make the achievement of eminence in Western culture more likely? An experiment by DePetrillo and Winner found that doing creative artwork elevated self-reported mood in college students in whom low mood had been induced by exposure to videos showing distressing scenes. By contrast, simply copying abstract designs or solving challenging verbal puzzles did not elevate mood significantly. The mood-elevating effects of creative artmaking may make artistic endeavors especially attractive to individuals with mood disorders; this may help explain the over-representation of individuals with mood disorders among creative artists.

Eminence Revisited: A Complex Equation

Robert Albert identified a finite number of early personal and family factors that may together yield a ‘multiplier effect’ on eminent achievement. These include parental and sibling characteristics, and family birth order. Many positive forces combine to provide personal strength, support, opportunity, and expertise. Albert also found that long-standing family interests or capacities were frequently made available to the individual, allowing a channeling of interests and a long-term immersion in a subject, with support of family and culture.

Strong motivation is important for creativity, especially for the creator with a bipolar disorder. Ruth Richards and Dennis Kinney have shown a definite preference for work-related over leisure-related creativity among bipolar subjects in a sample of everyday creators. (By contrast, other research by Kinney, Richards, and colleagues found that individuals with schizotypal personality traits, which are elevated in relatives of schizophrenia patients, showed greater preference for leisure-related creativity.) A number of personality factors linked with bipolar mood disorders have been proposed that may raise the chance of eminent recognition when creative talent is already present. These factors include a driven work orientation, an ability to think in broad and ambitious terms, altruistic and socially concerned motives that may accompany mood elevation, a sense of ‘standing apart’ from the mainstream, and a need for external validation.

Here, results have been similar for individuals in both artistic and nonartistic fields. Important personal characteristics associated with creativity have included contrariness, capacity for solitude, physical illness or disability, drive for supremacy, production of work with a personal seal or signature, and a psychological ‘unease’ or drive. Mental disturbance is included in the ‘unease.’ Research on eminent individuals has found that psychopathology was four times as common

in the most eminent as in the less eminent individuals. The same research found that 78% of the most eminent individuals (vs. 55% of the less eminent) developed a psychiatric problem.

Contexts of Eminence: Creative Insight, Systems, and Chaos Theory

Eminence is a pattern in time and space that emerges around a creative person in a context. The eminent creator may be viewed as an open system, in tune with a culture, that can express where it wants (or needs) to go. The creative person may conceivably sit on a real or metaphorical edge of chaos – revealing or facilitating new creative insights about to erupt. This may reorganize the mental field in a dramatic new way (a mental ‘butterfly effect,’ or an irreversible avalanche of new awarenesses and mental reframing). This self-organizing process shows the nonlinear, irreversible, and dramatic sensitivity to initial conditions that is characteristic of chaotic systems. People with mood swings and mild mood elevation might find such an ‘edge-of-chaos’ effect, or mental shift, particularly available, as Richards proposes, for example, in association with tendencies toward overinclusion (or looser associations). Physical illness may also provide an opportunity for creative (and chaotic) reorganization and transformation, as Zausner has proposed.

Here is one societal role for the creator: seeding of culture with new ideas, some to be kept and some to be rejected. Eminence can be conferred on an innovation if a large enough audience has their own productive creative response. The idea can bring on similar mental shifts – avalanches of new ideas, or mental reframings – in an appreciative public. However, a reframing may not always be welcome in a particular era, in which case the creator may be ostracized, and even pathologized. Among those most apt to take risks such as being ostracized may be people who already ‘stand apart’ and are seen as deviant.

Everyday Creativity and Mood Disorders: Considerations

Subjects Chosen Using Clinical Versus Creative Criteria

Let us now turn things around and start with subjects who are chosen because of their psychopathology, rather than their creativity. If all creative writers had mood disorders, one would not expect everyone with a mood disorder to be a creative writer. One still does hear, however, people making these associations of mood disorders with creativity as if the association were (a) always true and (b) reversible. It is not so. We are talking, rather, about associations that are predictive, probabilistic, and directional. Creative writers, or indeed people in any field who have achieved a measure of success, bring together a constellation of intellectual and personal qualities and strengths. This constellation might not be the case for the average person on the street, or for someone with a severe mood disorder. When we focus on eminent creators, we are not at the less-productive extremes of bipolar liability in the inverted-U relationship between symptomatology and creativity, but rather are somewhere into the more functional middle (raised) segment of the inverted-U curve.

Special Abilities or a Way of Being?

One also needs to consider the area of endeavor. Special ability factors may be one ingredient in creativity, and cognitive style another. Researchers at the Institute of Personality Assessment and Research (IPAR) at the University of California, Berkeley, found broad evidence of a preference for originality in well-known creators in many fields. In fact, if a link with mood disorders involves adaptive factors showing genetic influence, one would expect such adaptation to be general, and not to be constrained, for example, to a limited area such as verbal ability.

Studies of families also contribute evidence. Relatives of creative persons in a given field, such as the arts, were not necessarily in that same field themselves, even though they showed higher than average creativity. These findings are consistent with IPAR's finding of a general 'disposition toward originality' that tends to run in families. Whether or not one holds a unitary view of intelligence, or instead leans toward a belief in multiple intelligences, the secret ingredient for creativity may involve a superimposed style of living and working that brings originality to one's efforts. Artistic or other special skills may be necessary for some types of creative work, but they are not sufficient. It is one thing to copy a Rembrandt, but another thing to be Rembrandt.

Compensatory Advantage? A Key Study and Method

The phenomenon of compensatory advantage may be relevant to creative ability. In sickle cell anemia, inheritance of the same recessive mutant gene from both parents leads to serious and often fatal medical disease. By contrast, inheritance of only one copy of the mutant gene (i.e., carrier state) may often result in only a mild anemia, while providing a compensatory advantage of resistance to malaria. In the case of some psychiatric illnesses such as bipolar disorder, while the genetic model may be more complex, it seems plausible that certain genes that increase risk for the disorder may also carry a compensatory advantage involving increased creative potential. The numbers of people affected is important; millions of people are affected by mood disorders, so that the benefit of increased creativity would affect not just the achievements of a handful of highly eminent people, but the everyday lives of millions of individuals. This phenomenon may also involve a more complex variant of genetically based selection, favoring people who may contribute to our memetic (or informational) evolution, as well as genetic evolution. Creative individuals facilitate growth in the units of information (or memes) that reflect creativity in our world, and these may subsequently affect genetic survival, as in the discovery of fire or of penicillin.

Accordingly, an inverted-U association has been hypothesized between creativity and degree of bipolar symptomatology. Richards, Kinney, and colleagues compared the creativity of individuals with bipolar disorder, patients with cyclothymia, and their psychiatrically normal relatives to each other, as well as to psychiatrically normal control subjects, and to individuals with another type of psychiatric diagnosis. The creativity variable involved a measure of the highest or peak level of real-life broad-based everyday creativity manifested in vocational and avocational activities, rated using the Lifetime

Creativity Scales, consistent with evidence of a disposition toward originality. The mean rating for everyday peak creativity was higher among the clinical sample (comprised of bipolar and cyclothymic patients and the normal relatives) than controls, with the cyclothymic group showing higher creativity than the bipolar group. However, another group was also highly creative: the psychiatrically normal relatives of bipolar patients.

This is an important finding, indicating that the severe pain and suffering associated with full-blown mood disorders were not necessary for the hypothesized creative advantage. Nor did psychiatric normalcy explain the high level of creativity in the healthy relatives of bipolar patients, since the normal control subjects were not so distinguished. Interestingly, other researchers have also found advantages on achievement in general in relatives of bipolar individuals. These findings may support the inverted-U effect, if a subclinical hypomania or other mild affect is what produced the elevated creativity in the healthy relatives of bipolar patients. These results are also consistent with other research findings: (a) that increased creativity is linked to intermediate, rather than high or low, levels of Eysenck's psychoticism variable; (b) of subtle findings of thought eccentricity found in the normal relatives of bipolar patients; and (c) of higher mean scores on a clinical hypomania scale in creative college students, in the work of Schuldberg and others.

Notably, studies of overinclusive thinking compared bipolar patients and eminent creators in their styles of thinking. Beginning with Andreasen's work in the 1970s, similarities have been found between writers and bipolar patients in particular, though with some key differences. Patients were less likely than the writers to make *adaptive* use of overinclusive thoughts. Related research found that eminent creators, despite having high mean scores on many Minnesota Multiphasic Personality Inventory psychopathology scales, also showed high scores for ego strength.

Conceivably, with treatment, certain mood-disordered people may show not just decreased symptomatology but increased creative productivity. This research underscores the potential value of eccentricity, and the importance of not prematurely judging creative people as ill. Unconventional thinking styles do not necessarily mean pathology – indeed, sometimes may be exceptionally valuable.

State Effects: Is a Good Mood a Good Thing?

When asked directly, noneminent bipolar patients reported greater creativity during mild mood elevations than during episodes of mania or depression. Their creative periods were associated with characteristics of spontaneous exuberance and cognitive facility, including rapid thinking and fluent associations. Eminent artists and scientists gave similar reports, as the great majority had also experienced intense creative periods associated with many characteristics of mild hypomania.

The prominence in a sample of eminent writers of bipolar II disorder, rather than bipolar I disorder, with its more extreme mood elevations, is also notable. Mechanisms for these cognitive, affective, and motivational advantages of hypomania have been proposed. Other studies have found that even in the general, rather than the psychiatric, population, mild mood

elevation – say, from watching a comedy film – can directly enhance creative problem solving. Mood elevation may also enhance cognitive style factors that can be relevant to creativity, such as unusual associations and the creative style factor of overinclusion. For example, in classifying things as flat, the overinclusive person might mentally stretch a little further, and pull in more imaginative possibilities (or some might say loose, or inappropriate ones). Flat things, then, might include items such as a piece of paper, a dinner plate, a postage stamp, a body of water, the crown of the head of a person with a crew cut, and the nose of a professional boxer. Certainly, thought as well as affect is relevant to this cognitive style factor. Notably, evidence has been found of overinclusive thinking in creative samples, linked with a psychoticism dimension, as Richards has noted in discussing Eysenck's work.

State Effects: What About Negative Mood?

Unipolar patients have reported a heightened sensitivity when depressed. They do not, however, necessarily report advantages ascribed by bipolar subjects to elevated mood states. Despite preliminary evidence that people with a history of depression may show higher everyday creativity if they have a family history of bipolar disorders, one cannot necessarily conclude that it is the episodes of the depression themselves that are conducive to creativity. Rather, it may be associated with sub-clinical hypomanic highs related to a family history of bipolar disorder.

Some research suggests that negative affect does not make a particular contribution to creativity. An inverse relationship has been shown between negative affect and creative personality patterns. However, others have linked negative mood with greater creative problem solving.

Research on children's play has shown that negative affect, experienced as part of a mixed affective state – in which one is overcoming a troubling difficulty and is triumphing – can also carry a positive affective charge. Indeed, much creative work in the arts deals with gaining perspective on, expressing, and transforming hardship and adversity. It has been suggested that the alternation of mood states in bipolar individuals may enhance both (a) creativity ability (enriching the interconnection of positive and negative mood-linked schemas in memory storage – schemas that might otherwise be stored separately in a mood-congruent structure), and (b) creative motivation (where an inevitable succession of negative and positive mood states enhances the conviction that mood will change, and activity may help, as with a hypomanic response to depression). Hence, faced with adversity, one is able to learn a style of approach and creatively solving a problem, rather than a style of avoidance.

State and Trait Effects: What About the Normal Relatives of Bipolars?

Of great importance, for manic, schizoaffective, and schizophrenic patients, related (though very much muted) forms of thought disorder were found to be more common in their respective first-degree relatives, even those relatives who were not themselves clinically ill. This is consistent with the finding of elevated creativity in, for instance, the normal relatives of

bipolars, and in depressed individuals with a bipolar family history, and it suggests operation of some subtle cognitive factors associated with the liability for bipolar disorder. In fact, there are particular qualitative patterns of unusual thinking that differentiate mania from schizophrenia, patterns that might yield higher creative potential in the former. For bipolar disorders, this involves combinatory thinking, with incongruous combinations of ideas and playful confabulation, as described in Philip Holzman and Mary Hollis Johnston's Thought Disorder Index. These patterns involve loosely tied together ideas and often have a playful quality to their production. These styles produce novel combinations of ideas and unconventional perspectives that may be valuable in generating innovative solutions to problems that would not occur to other people.

Evolutionary Significance

In October 1996, an invitational conference in New York, on Manic-Depressive Illness: Evolutionary and Ethical Issues, was convened by Kay Jamison of Johns Hopkins and Robert Cook-Deegan of the National Academy of Sciences. Participants came from around the world to discuss the genetic and environmental factors, social costs, and adaptive value of bipolar disorder. The participants, who included distinguished scientists and clinicians, urged caution, in this burgeoning era of genetic engineering, against any precipitous efforts to remove from the population gene(s) that increase liability for bipolar disorder, given that this liability is complex, not fully understood, and may have creative advantages for individuals and society.

Everyday Creativity and Survival

Multiple authors have noted that a link of bipolar risk with creativity (and perhaps also with leadership) could help explain why genes that contribute to bipolar disorders have not been selected against, given the increased rates of mortality and morbidity in these disorders. A compensatory reproductive advantage would presumably help keep bipolar disorders (and genes that help cause them) around. According to Robert Albert, (a) any form of human development and behavior with a substantial degree of heredity may well involve an evolutionary process, and (b) both genetics and environment are apt to be involved, providing flexibility toward changing environmental conditions.

One must ask whether such an advantage of genes for bipolar disorder liability would operate at the level of eminent or everyday creativity. This is a critical point. A handful of eminent people, however dramatic their reproductive power, could not maintain bipolar spectrum disorders at a rate as high as 4–5% of the population. Everyday creativity could be key in this regard. The liability for bipolar disorders must play out in everyday life in order to maintain an adaptive value and reproductive advantage great enough to compensate for the higher mortality associated with bipolar disorder. The prevalence of eminent creativity may be related to this, however, since the receptive ground for everyday creativity may provide (a) greater openness to the innovations of our eminent and

exceptional leaders, and (b) the ability to produce more such leaders than would a conservative culture – individuals who symbolize for all of us new trends and innovative ideas.

Candidates for a reproductive advantage include traits related directly to mood elevation, or even a sometimes associated hypersexuality, as well as the creative behaviours themselves and associated traits. This explanation demands that one ask not only about genes, or biological units of heredity, but also about memes, or units of information in culture. Examples of memes are an equation, an idea, or a song. Indeed, we know that the producers of ideas help the survival of society, both at the everyday and at the eminent level, and that society may help such contributors to survive. Here is a critical interaction between biological and cultural evolution.

When Illness Yields Creativity: Two Models

There is more than one way in which illness and health may be intertwined, so as to have immediate, as well as ongoing, evolutionary effects. We first present a five-part general typology of direct and indirect relations between creativity and psychopathology, which is summarized (see [Table 1](#)) using examples from mood disorders. Next, this typology is used as a framework for two biological models, showing how creativity and illness can be intertwined.

Creativity and Psychopathology: A Five-Part Typology

Factors connecting creativity and psychopathology can involve biological, psychological, and social factors – and not

surprisingly, the patterns can be complex. A classification scheme can help. Factors affecting both ability and motivation for creativity occur, as do direct and indirect effects. (Factors affecting motivation can be classified as indirect – as background enhancers of the application of creative abilities.) There are also directional issues – for example, times when creativity can lead to psychiatric problems, and ways that illness can impact creativity. These relationships can be multiple and overlapping. The letters P and C are used for psychopathology and creativity, respectively (or some aspect of these). T refers to a third factor (or factors) that may independently influence aspects of both creativity and psychopathology. Examples relating to mood disorders are given below (see [Table 1](#)) for each pattern.

Biological Models and Psychological Applications

Two biological models follow that may be linked to mood disorders and may also be viewed in terms of a combination of categories in this typology.

Compensatory advantage

The existence of a genes for a medical problem – If present at an attenuated level – can carry an advantage and a low-enough cost – benefit ratio that there may be adaptive, and even evolutionary, advantages overall in a population. The example of this in sickle cell anemia, both in the disease state (with two copies of a mutant gene) and the carrier state (one copy), was mentioned earlier. The more numerous carriers suffer relatively little but obtain a compensatory advantage: resistance to malaria.

Table 1 Typology of creativity and psychopathology with applications to mood disorders

1. *Direct relationship of pathology to creativity ($P \rightarrow C$)*. Aspects of psychopathology (P) can contribute directly to creative outcomes or processes (C). Consider Kay Jamison's *An Unquiet Mind*, a remarkable first-person account of bipolar disorder by an internationally known expert on mood disorders. Personal experience is relevant both to the content of the book and to aspects of creative process in writing it.
2. *Indirect relationship of pathology to creativity ($P \rightarrow T \rightarrow C$)*. Here, a third factor (T) intervenes between pathological and creative factors. Consider a person who does journal writing about mood states or conflicts, for personal reasons of catharsis, but comes to discover a greater creative potential and rewards. Novelist John Cheever, who suffered from depression, did youthful writings about family and school situations that are thought to have helped him personally. Such expression can free one up psychically and enhance one's perspective, empowerment, and general health. At best, it can put one in touch with more universal themes and altruistic motives. Individuals like Cheever may end up writing or creating for the benefit of others.
3. *Direct relationship of creativity to pathology ($C \rightarrow P$)*. Humanistic psychologist Rollo May, among others, wrote about the anxiety that may at times attend creative expression. Especially in the arts, one must be open to whatever comes up. The heightened sensitivity reported by people with unipolar or bipolar mood disorders could raise the odds at times of distress. In the best circumstances, such psychological discomfort and anxiety during the creative process can be an important step along the way to a more healthy and open personality. Hence, if creativity sometimes leads to such pathology in the short term, it can still ultimately lead to greater creativity and health.
4. *Indirect relationship of creativity to psychopathology ($C \rightarrow T \rightarrow P$)*. Here, the third or intervening factor is the emergent conflict that comes to consciousness during the act of creation. Consider, for example, problems with substance abuse as a less healthy response to conflict than the working through just described in paragraph 3 above. Substance abuse occurs more often with individuals with mood disorders than in the general population. Another example is the creative and outspoken schoolchild who is ostracized by peers, and misunderstood by teachers. Sometimes a seeming hyperactivity is an early indicator of later bipolar disorder. Reticece, withdrawal, or clowning around and behavior problems may occur in creative children, and should the child have familial tendencies toward depression, this too might become activated under stress. With more supportive environmental conditions, however, a better outcome can be possible.
5. *A third factor can affect both creativity and psychopathology ($C \leftarrow T \rightarrow P$)*. An important potential third factor is a familial liability for bipolar or manic-depressive illness. Having this liability may increase the odds of (a) problems related to mood swings, but also of (b) positive qualities related to creativity or leadership. These outcomes may occur separately or together in individuals, or across different family members, as found for instance by Andreasen, and by Richards and Kinney. This third factor could involve cognitive, affective, and/or motivational factors – thus bringing along with mood elevation, for example, a more overinclusive cognitive style (original thinking versus thought disorder), heightened emotional sensitivity (depth of appreciation versus emotional instability), and inspired motivation (energetic confidence versus grandiosity).

In the psychological model, creativity is the compensatory advantage. In the typology, familial liability (which includes genetic risk) is the third factor, which stands between the pathological and creative effects ($P \rightarrow T \rightarrow C$). This may be manifested in terms of cognitive, affective, and/or motivational effects.

Acquired immunity

This biological model is exemplified by infectious illnesses such as whooping cough. Childhood infection is relatively mild compared to the adult form of the illness. Early exposure (and immunization) is therefore useful as protection against adult illness. A resilient capacity can be developed, in this case through one's immune system. In the typology, this situation connects first to the mediated relationship ($P \rightarrow T \rightarrow C$), in which pathology leads to personal strength which enhances healthy function.

The psychological parallel is the large number of people, particularly eminent creators in the arts, who have suffered early adversity and high rates of mental illness. As one factor, when a child has a mood disorder, a parent is more likely to have one as well, and this can lead to many sequelae, including emotional distance, inconsistency, and early stress. When there is creative coping, this can be very important. Yet a great many people with early difficulty do not thrive. The important question is to find 'what makes the difference' – what intervening or 'third factors' (with $P \rightarrow T \rightarrow C$) may further a resilient outcome or a creative coping and survivor strategy.

Conclusions and Recommendations

Links with Mood Disorders: Yes, but They Are Complex

There is support for links between creativity and bipolar and unipolar mood disorders, and perhaps more importantly, with psychiatric family history and the underlying risk one carries, which might manifest in different ways. The manifestations of this risk differ in nature and intensity between eminent and everyday creators. For eminent creators, there is a high prevalence of mood disorders in the arts in particular, especially of bipolar disorders. Mild mood elevation seems particularly conducive to creative insight, potentially offering cognitive, affective, and motivational advantages. Outside of the arts, major mood disorders are less common, although more information is needed about mild or subtle mood swings or possible family psychiatric history. Perhaps aspects of a familial liability to bipolar disorder also help influence a drive toward eminence.

For everyday creators, it appears that relatively well-functioning individuals are most apt to display higher creativity at work or leisure, showing more *intermediate* levels of bipolar pathology, and sometimes even *normalcy*, against the background of a bipolar family history. Do note that eminent mood-disordered artists may also represent relatively well-functioning persons within the group of people with a particular diagnosis – although, of course, there are always exceptions. One must again differentiate psychological states from traits, noting, for instance, advantages of the *state* of mild mood elevation. Then there are potential benefits for creative ability and motivation. These benefits may involve, for ability, a more mindful awareness of one's own personal states and one's world, including the ability to link and access diverse affects

in memory storage. In the case of motivation, benefits may involve a growing sense – at least for some people who are properly 'immunized' – that one can face adversity and transform it creatively, rather than defend against it.

Resilience and Creative Confrontation – Some Special Roles?

There are interesting people – and interesting families – for whom psychological problems are more apt to occur, but perhaps with some freshness of vision as well. There is support for an evolutionary basis for this, and the suggestion of some adaptive value for society (if not always for individuals) potentially linked to a compensatory advantage.

Regarding personal or family history of bipolar disorders, the following points are partly supported and worthy of further study. Some individuals may be more apt to (a) stand apart from the mainstream, due to differences that include identified illness and its effect; (b) come up with new ideas as a behavioral norm, as well as to challenge old ones, and to do so often in the world of work and social contributions; (c) be more aware at times of what is going on in their immediate environment or in the world; (d) be more sensitively attuned to input in general; (e) for a subset of people, be more willing and able to face certain adversities head on, as per the model of acquired immunity; and (f) at times be more altruistically inclined in their creative intentions.

Evolutionary Shift – and Broadening the Acceptable Limits of Normality

The evolutionary hypothesis – that the spectrum of bipolar disorders (including unipolar disorder where there is a family history of bipolar disorders) have been favored through evolution – could draw on multiple advantages, as related to a reproductive advantage. With compensatory advantage, a genetically influenced advantage may relate to, and in evolutionary terms compensate for, the morbidity of mood disorders. With acquired immunity, the creative twig may be bent in a positive way for later personal resilience and creative coping.

A memetic shift may be necessary for successful survival in a changing world. We may need a different form of valuing human behavior that will embrace deviant seers and creators, and tolerate ambiguity in a rapidly evolving culture that must welcome new ideas. One should not assume that unconventional ideas and behaviors are pathological, simply because they are different – when they may actually lead to creative and healthful outcomes.

Birth Order

F J Sulloway, University of California, Berkeley, CA, USA

Glossary

Birth order The sequence by which children are born into a family. The most important birth-order positions are eldest, middle, and youngest. As a rule, birth-order differences in personality arise as a result of how children are raised (functional birth order, or rearing order) rather than the sequence in which they are born.

Five Factor Model of Personality A model based on the analysis of psychological questionnaires and natural language. Derived from factor analysis, this model posits the existence of five basic personality dimensions

(conscientiousness, agreeableness, openness to experience, extraversion, and neuroticism – also known as “the Big Five”).

Parental investment The nurturing that parents give to offspring, which can be emotional as well as physical. In Darwinian theory, parents are expected to invest differentially in offspring based on criteria such as age, sex, birth order, and cues of phenotypic quality. Parents make these discriminations in an effort to maximize their reproductive fitness – that is, the number and quality of offspring they successfully rear.

Birth Order and Evolutionary Psychology

In order to understand the association between birth order and creativity, it is first useful to review the relationship between birth order and personality, which owes itself to biological as well as environmental influences. Because there are no genes for being a firstborn or a laterborn, birth-order effects represent one of the best demonstrations of the power of the environment. Nevertheless, birth order interacts with other influences on human behavior, including genetic predispositions, that are known to be under biological control. Biological influences on personality may be separated into ultimate and proximate causes. Ultimate causes are those that are attributable to evolution by natural selection. By contrast, proximate causes encompass those physiological influences operating during the lifetime of the organism. Proximate causes also include environmental influences, which typically interact with genetic and physiological processes.

Viewed in these terms, sibling rivalry provides an ultimate cause of some aspects of personality development. Darwin's theory of natural selection offers an explanation for this part of the story, because it tells us that siblings are biologically driven to compete for parental favor. On average, siblings share half of their genes. In the early 1960s, William Hamilton recognized that natural selection acts to maximize what he termed ‘inclusive fitness.’ This form of Darwinian fitness is defined as an individual's own reproductive success, together with his contribution to the reproductive success of close relatives, discounted according to their coefficient of relatedness. Based on Hamilton's theory, siblings are expected to compete for scarce resources whenever the benefits of doing so are greater than twice the costs. In general, an offspring's idea of fairness is to keep two-thirds of any scarce resource for him- or herself and give only one-third to a sibling. Competition for parental investment is the main cause of sibling rivalry.

By itself, competition among siblings does not lead to birth-order differences in personality. But birth order provides a

powerful proximate (and environmental) source of sibling strategies. These tactical differences arise because birth order is correlated with differences in age, size, power, and status within the family. These physical and social disparities cause siblings to experience family relationships in dissimilar ways and to pursue differing ways of optimizing their parents' investment in their welfare.

Competition for parental love and favor has been an important driving force in human evolution, just as have parental decisions about how to invest in their offspring. Before 1800, half of all children did not survive childhood, and even minor differences in parental favor would have increased a child's chances of reaching adulthood. Children who lived long enough to become the eldest in a family were often a better Darwinian bet for their parents, because they had survived the perilous years of life and were more likely than their younger brothers and sisters to reach the age of reproduction and to pass on their parents' genes. In every society surveyed by anthropologists, eldest children are accorded higher status. For example, many traditional societies condone infanticide, especially when a child is deformed or when a slightly older infant is still breast-feeding, but no society condones the killing of the older of two siblings.

Parental investment strategies tend to be variable because birth order is only one of many relevant factors in these decisions. Besides taking into account the relative quality of their offspring, parents may invest differently in children based on such factors as the parents' age and the resources available to them. Primogeniture has generally been practiced by affluent parents in agrarian societies, where wealth is tied to land; but this inheritance system is much less common in mercantile societies where wealth can be acquired rapidly through entrepreneurship. Under these conditions, parents tend to hedge their bets by investing equally in all of their offspring.

Even if parents do not favor one child over another, sibling rivalry influences the dynamics of family life because competition serves to limit favoritism. Such competition typically

involves the cultivation of family niches that correspond to differences in birth order. That families provide offspring with a series of niches is a conclusion supported by research in behavioral genetics. One of the most remarkable findings in psychology during the last two decades is the discovery that brothers and sisters raised together are almost as different in their personalities as people who grow up in separate families. Based on studies of twins raised together and apart, behavioral geneticists have concluded that only about 5% of the variance in individual personality traits is attributable to the shared environment – that is, growing up in the same family – whereas 35% can be assigned to the nonshared environment. About 40% of the overall variance is believed to be genetic, and the remaining 20% is attributable to errors of measurement. These findings have begun to reshape the understanding of personality development by suggesting that the family is not a single environment, but rather a collection of microenvironments or ‘niches.’ The main reason why the shared family environment does not have a greater impact on personality is that very little of the family experience is actually shared. For example, brothers and sisters are at different ages when they experience the same events, and siblings often interpret shared experiences differently. Two particularly important and systematic sources of non-shared experiences are gender and birth order.

Birth Order and Personality

Psychologists have investigated the consequences of birth order ever since Charles Darwin’s cousin Francis Galton reported, in 1874, that eldest sons were overrepresented as members of the Royal Society. After breaking away from Sigmund Freud in 1910 to found a variant school of psychoanalysis, Alfred Adler highlighted social influences on personality, including birth order. A secondborn, Adler regarded firstborns as ‘power-hungry conservatives.’ He characterized middleborns as competitive, and youngest children as spoiled and lazy.

During the half-century since Adler’s speculations, psychologists have conducted more than 2000 studies on the subject. This literature has often been faulted, and critics have rightly argued that the findings conflict and that most studies are inadequately controlled for social class, sibship size, and other background influences that correlate with birth order and can lead to false conclusions. The reality of these reported differences is nevertheless supported by meta-analysis – a technique for aggregating findings from different studies in order to increase statistical power and reliability. Considering those well-designed studies that adjust for social class or sibship size, meta-analysis reveals consistent birth-order differences for many personality traits. These findings may be summarized in terms of the Five Factor Model of personality.

Controlled studies generally report that firstborns are more *conscientious* than laterborns, a difference that is exemplified by their being more responsible, ambitious, organized, and academically successful. Laterborns appear to be more *agreeable* than firstborns, in the sense of being more tender-minded, accommodating, and altruistic. Laterborns are also more *open to experience*, as expressed by their being more adventurous and unconventional. Differences by birth order

are more restricted for the two remaining dimensions of the Five Factor Model. Firstborns appear to be more *neurotic* than laterborns, in the sense of being temperamental and anxious about their status. In addition, firstborns are more *extraverted* than laterborns, in the sense of being assertive and dominant, whereas laterborns are more extraverted in the sense of being sociable and fun-loving. Dominance and sociability are substantially different personality traits, even though they are classified together within the Five Factor Model. Firstborns tend to have higher IQs than laterborns, but this difference is small, especially after being controlled for differences in family size. On average, IQ falls one point with each increase in birth rank within the family. (Proponents of the Five Factor Model consider IQ to be a sixth factor, largely independent of personality.)

The personality differences that I have just reviewed are generally consistent with a Darwinian framework, albeit with an emphasis on adaptation through learning. Unlike the propensity to compete with one’s siblings, which is an ultimate cause of sibling conflicts, personality is a product of innumerable proximate causes that spur individuals to adapt themselves to the surrounding world. Firstborns often seek the favor of their parents by acting as a surrogate parent toward their younger siblings. As a result, firstborns tend to be parent-identified, conscientious, and respectful of authority. Laterborns cannot baby-sit themselves, so they look for an unoccupied family niche, in part by cultivating latent talents that can be discovered only through experimentation. For this reason, they are often more exploratory and open to experience. Another reason for the divergent personalities of siblings is the different strategies they employ in their relations with one another. These strategies involve behaviors that are typical of mammalian dominance hierarchies. Because firstborns are bigger, they are more likely to employ physical aggression and intimidation, and in general they are more likely to boss and dominate their younger brothers and sisters. Laterborns tend to use low-power strategies, such as whining, pleading, cajoling, humor, social intelligence, and, whenever expedient, appealing to parents for help. Two or more laterborns may also join in coalitions against the firstborn.

A Darwinian approach also leads to specific predictions about middle children, who lack the advantages of being either first or last. When resources are scarce, parents are expected to invest preferentially in firstborns because they are the first to reproduce. Older parents are expected to invest preferentially in lastborns because these offspring are the most vulnerable to disease and, after parents have ceased reproducing, are the last children they will ever have. As Catherine Salmon and Martin Daly have shown, middle children often respond to their Darwinian handicap by becoming peer-oriented and independent of the family. Compared with firstborns and lastborns, middle children are less closely identified with the family, less likely to turn to their parents for help in an emergency, and less likely to report having been loved during childhood. Compared with their siblings, middle children typically live farther away from their parents. In addition, they are the least likely sibling group to visit, and to encourage their own children to visit, close kin. Consistent with their greater allegiance to the peer group, middle children also are the most inclined to diplomacy and cooperation, strategies that may reflect

their proclivity for mediating disputes between their siblings. Martin Luther King, Jr., the middle of three children, got his start as a champion of nonviolent reform by trying to prevent his younger brother from teasing their older sister.

Only children represent a controlled experiment in birth-order research. Because they experience no sibling rivalry, they are not driven to occupy a specific family niche. Like other firstborns, they are generally ambitious and conform to parental authority, because these attributes are valued by parents. Contrary to psychological folklore, only children do not appear to be more neurotic or less sociable than other children. There is often a greater difference between a firstborn and a secondborn child, or between a secondborn and a thirdborn, than there is between the firstborn and the thirdborn. The reason is that sibling competition promotes mutual differentiation in order to minimize direct conflicts, and children who are farther apart in age have less need to compete. This process of sibling differentiation, which is sometimes called deidentification, extends to relationships with parents. When a firstborn identifies more strongly with one parent, the secondborn is likely to identify more strongly with the other parent.

Some of these contrasts are striking. Voltaire, the third of three children, had an acrimonious relationship with his elder brother Armand, who became a follower of the Jansenists, a fanatical Catholic sect. Voltaire was particularly repelled by Armand's belief in the need to forgo life's pleasures in order to win God's grace. As a leader of the French Enlightenment, Voltaire was especially noted for his relentless attacks on the Catholic Church. He chose literature as a profession partly to spite his brother, whom he had repeatedly bested in impromptu poetry contests devised by his family.

A different example of sibling contrasts involves the consumer rights advocate Ralph Nader and his three older siblings. In early adolescence, the Nader children took a globe of the world, divided it into four equal portions, and assigned one part to each child. Thereafter, each specialized in the history, culture, and languages of his or her own quarter of the globe. By minimizing direct competition, the Naders were also cooperatively pooling their resources as a family unit, collectively enabling them to learn more about the world. As Darwin recognized in the *Origin of Species* (1859), diversification is an effective way to reduce competition while also realizing the benefits stemming from the division of labor.

Direct Sibling Comparisons

Birth-order differences in personality vary in magnitude and sometimes even in direction, depending on how they are measured. When assessed by self-report questionnaires, birth-order effects are typically modest and nonsignificant. Yet systematic differences by birth order are generally found when parents rate their own offspring or when siblings compare themselves with one another. In a recent study by Frank Sulloway, 660 business leaders were surveyed. In self-reported ratings, firstborn CEOs did not differ significantly from laterborns on ten of the 11 personality traits included in the survey. After providing these self-assessments, respondents were asked to compare themselves with their siblings, using the same 11 personality scales. A comparative method of assessment possesses several advantages over more customary methods of

self-report. In particular, direct comparison anchors the scales. Additionally, comparative judgments among siblings eliminate any confounding effects associated with differences between families. Using such comparisons, eight of the 11 traits included in the survey elicited significant differences by birth order. Relative to their older siblings, laterborn business leaders were more tender-minded, cooperative, flexible, submissive, empathetic, liberal, unconventional, and even-tempered. Overall, comparative ratings resulted in birth-order differences that were five times as large as those previously obtained without using direct comparisons.

A follow-up study involving 6053 individuals aged 8 to 95 (mean age = 36.8, $SD = 17.1$) has yielded similar results for a broad array of personality traits. Subjects rated themselves on nine-step bipolar scales using adjective pairs that were chosen to represent the 30 facets of the NEO PI-R, a comprehensive personality inventory based on the Five Factor Model. Firstborns were asked to rate both themselves and their next younger sibling, whereas laterborns were asked to rate themselves and their next older sibling. Based on direct sibling comparisons, 23 of the 30 bipolar adjective pairs yielded significant differences, and 26 of the 30 adjective pairs produced correlations in the expected direction. As anticipated, firstborns were judged to be more conscientious than their younger siblings, whereas laterborns were judged as being more agreeable and open to experience. For neuroticism, a dimension for which birth-order differences were expected to be mixed, firstborns were predicted to be more anxious and quicker to anger – expectations that were both confirmed. Laterborns were predicted to be more depressed, vulnerable, self-conscious, and impulsive, but only the last two predictions were confirmed. As anticipated, results for extraversion were also mixed. Laterborns were more affectionate, fun-loving, and inclined to seek excitement. Firstborns were more energetic and dominant.

Controlling for age, sex, sibship size, and social class, the partial correlation between birth order and a scale score of predicted differences was 0.20, with birth order accounting for 4.1% of the variance. Two other family background variables – sibship size and social class – account for less than 0.1% of the variance in this scale score of predicted differences, as also does age. By comparison, sex explains 2.1% of the variance. (Laterborn personality traits resemble those observed in females.) Controlled for the linear effect of birth order on the scale score, there was also a significant quadratic trend: middle children scored higher than last-borns on some personality scales, particularly those related to agreeableness (Table 1).

Measured in terms of an overall scale score that reflects predictions about birth order, age and sex account for substantially less variance in personality scores than does birth order. It is important to note, however, that age and sex explain considerably more about personality as a whole than they do about birth-order-related traits. Sex differences in my study account for 8.3% of the variance in dimension scores for the Big Five, and age explains another 2.6% of the variance. In accounting for 4.1% of the variance in these same dimension scores, birth order is substantially more influential than age, but less so than sex. Still, on two dimensions of the Five Factor Model (conscientiousness and extraversion), birth order has greater influence than either age or sex.

Table 1 Birth-order effects in scale scores for the big five personality dimensions based on direct sibling comparisons

Personality dimension ^a	Partial correlation with birth order ^b	N	p <
Conscientiousness ● Firstborns are more <i>deliberate, dutiful, effective, energetic,^a hardworking, organized, self-disciplined, and under control^a</i>	-0.18	4507	0.0001
Agreeableness ● Laterborns are more <i>acquiescent, cooperative, easygoing,^a modest, straightforward, unassertive/submissive,^a tender-minded, and trusting</i>	0.10	4510	0.0001
Openness to experience ● Laterborns are more esthetically inclined, <i>prone to fantasy, attentive to inner feelings, untraditional, attracted by novelty, and drawn to ideas^c</i>	0.08	4484	0.0001
Extraversion ● Laterborns are more <i>affectionate, excitement-seeking, fun-loving, and gregarious</i>	0.14	4404	0.0001
Neuroticism ● Firstborns are more <i>anxious</i> , as well as more prone to depression and feelings of vulnerability	-0.04	4278	0.001
● Laterborns are more <i>self-conscious</i>	0.05	3548	0.005
Scale score for personality differences, as predicted ^d	0.20	4177	0.0001

^aEach of the 30 bipolar adjective pairs, representing the 30 facets of the NEO PI-R, is classified under the Big Five dimension on which it has its highest factor loading. Four of the 30 adjective pairs have their highest loading on a personality dimension other than the one for which they were selected. 'Assertive (dominant)/unassertive (submissive)' has its highest loading on Agreeableness (-0.54) rather than Extraversion (0.32). Similarly, 'quick to anger/easygoing' has its highest loading on Agreeableness (-0.55) rather than Neuroticism (0.47). 'Impulsive/under control' has its highest loading on Conscientiousness (-0.59) rather than Neuroticism (0.24). 'Energetic / leisurely' has its highest loading on Conscientiousness (0.47) rather than Extraversion (0.28).

^bA positive partial correlation denotes a higher score for laterborns. For each bipolar trait, a sibling difference score was calculated using z-scores and then used to compute each scale score in terms of predicted differences. Italicized traits exhibit significant birth-order differences. (All statistical tests are two tailed.) All partial correlations are controlled for age, sex, sibship size, and social class. All dimension scale scores except Neuroticism exhibit a significant quadratic effect, controlled for the linear trend, indicating a higher score for middleborns. For one dimension (Agreeableness), the quadratic trend is larger than the linear trend. Excluded from these statistical results are 548 only children, 71 twins, 112 subjects reporting an age gap of more than 9 years between themselves and the sibling they also rated, 86 subjects whose biological and functional birth orders do not coincide, and 726 subjects who did not provide information on one of more of the dependent or independent variables.

^cBeing 'drawn to ideas' was predicted to be a firstborn trait.

^dSome respondents made ratings on fewer than 30 bipolar adjective pairs. In these cases, scale scores have been computed from the observed data.

One should bear in mind that birth order is only a proxy for the real causes that lie behind sibling differences in personality, namely, disparities in age, size, status, and power within the family system. Not all firstborns adopt the role of a surrogate parent toward younger siblings, and some firstborns are less bossy than others. Individual differences in physical size, temperament, and opportunities for surrogate parenting help to explain why some individuals deviate from the patterns of personality that are generally expected by birth order. In the study summarized in **Table 1**, individuals were asked to what extent, during childhood, they acted as a surrogate parent toward their siblings, and also to what extent they bossed their siblings around. High scores for surrogate parenting behavior and bossiness reflect typical firstborn behaviors and are strongly correlated with birth order ($r = -0.56$ for the composite measure). This indicator of family niches also accounts for 10.5% of the variance in personality scores, making it considerably better at predicting personality than any other variable in the study. The predictive success of this variable lies in large part in its ability to account for exceptions to predictions based on birth order. For example, laterborns (often eldest daughters) sometimes report having done substantial surrogate parenting with respect to their younger siblings. These individuals also tend to describe themselves as having firstborn personality traits.

Other studies using the NEO Personality Inventory and comparable instruments have generally yielded null results,

although most of these studies have possessed only moderate statistical power and none have employed the method of direct sibling comparison. Based on similar discrepancies between self-report ratings, which often yield meager results, and significant differences as judged by family members, some researchers have argued that birth-order effects are parent specific and do not hold up outside the family.

When assessed meta-analytically, however, studies involving nonfamily members exhibit significantly more findings of a confirmatory nature than are expected by chance. Confirmatory findings are also especially likely to occur whenever studies involve real-life behavior. In addition, if birth-order effects are specific only to childhood (and the family milieu), one might expect these differences to diminish with age. In the study reviewed in **Table 1**, birth-order effects do decrease modestly with age for conscientiousness, but they increase modestly for agreeableness. Overall, there is not a significant diminution in the scale score for predicted birth-order effects by age.

The method of direct sibling comparison does not prove that birth-order differences in personality exist outside the family milieu. Direct sibling comparisons may also be susceptible to 'contrast effects,' whereby small but real differences between siblings are magnified, exaggerating the variance explained by birth order. However, when the scores in **Table 1** for direct sibling comparisons are transformed into binary outcomes (i.e., being higher or lower than a sibling on each trait), birth-order effects are only slightly reduced.

Another possibility is that these comparative measures reflect shared stereotypes about personality, rather than true differences. In an effort to determine whether birth-order differences are recognized by people other than siblings, study participants were asked to rate their spouses. Significant birth-order differences emerged in the expected direction, although the mean effect size for the Big Five personality dimensions is somewhat smaller than for direct sibling comparisons. Controlling for age, sex, sibship size, and social class, the partial correlation among spouses between birth order and a scale score for predicted personality differences is 0.12, which accounts for 1.4% of the variance ($N = 822$).

An analysis of the scores for individual traits reveals that spouses are detecting the same birth-order differences that they reveal when they compare themselves with a sibling. A convenient way of demonstrating this point is to compare the effect sizes for birth order, on a trait-by-trait basis, with the effect sizes for the same traits as judged by spouses. These two sets of effect sizes are substantially correlated ($r = 0.61$, $N = 30$ traits, $p < .001$). In other words, those traits that are strongly associated with birth order in sibling relationships are the *same* traits that are strongly associated with birth order in married couples. Relative to firstborn spouses, for example, laterborn spouses are perceived to be less conscientious, but more agreeable, extraverted, and open to experience. A similar pattern in birth-order effects is found among college students who rated both a sibling and a roommate ($r = 0.72$, $N = 30$ traits, $p < 0.001$; for roommates, the partial correlation between birth order and a scale score for predicted personality traits is 0.16, $N = 165$, $p < 0.05$). Thus birth-order differences are not restricted to family members or the family milieu, as some psychologists have claimed. Rather, these differences tend to manifest themselves in intimate living situations.

Gender, Age Spacing, and Other Moderating Influences

Birth order is only one influence among many that contribute to the development of personality. Accordingly, there are exceptions to any generalization on this topic. The largest source of exceptions are those arising from genetic differences, which collectively explain about 40% of the variance in individual traits. Additionally, as children grow up and spend more time outside the family, they are increasingly influenced by peer groups and by life experience more generally. Some of these extrafamilial influences may nevertheless reflect differences that already exist between siblings.

There is growing evidence that some birth-order differences in personality are influenced biologically by the prenatal environment. Among males (but not among females), laterborns are more likely to become homosexuals. Unlike other behavioral effects associated with birth order, the operative factor is number of older brothers rather than relative birth rank from eldest to youngest child. In other words, a lastborn male who is the eldest of his sex is no more likely to become a homosexual than is a firstborn. These findings can be explained by assuming that a small proportion of mothers develop antibodies to one of the male-specific minor histocompatibility antigens.

It has been hypothesized that such immunological responses prevent subsequent male fetuses from being fully transformed from female to male.

These findings about male homosexuality suggest that other aspects of personality – specifically, those involving gender-related traits such as tender-mindedness – might also be influenced by the prenatal environment. If such biological effects exist, they appear to be very small in normal populations. For example, meta-analysis of the birth-order literature reveals no significant difference in the frequency of birth-order effects by sex, including for behaviors specifically related to agreeableness and extraversion, which include many gender-related traits. In the study reviewed in [Table 1](#), birth-order effects were just as substantial among women as among men. For males, moreover, number of elder brothers had no relationship with gender-related traits, with birth order being controlled. In short, the link between number of elder brothers and gender-related traits appears to reflect a developmental outcome of nonpsychological origin that is confined to male homosexuals.

Gender also contributes to personality, doing so in ways that parallel the influence of birth order on some personality dimensions – particularly extraversion and agreeableness. These similarities arise because birth order and gender have comparable effects on the strategies siblings use as they jockey for position within the family. Partly for genetic reasons and partly because of socialization, females tend to be less aggressive than males, just as laterborns tend to be less aggressive than firstborns. Gender also modifies the forms taken by aggression. Firstborn males are more physically aggressive than laterborn males, whereas firstborn females are more verbally aggressive. In addition, males and firstborns tend to be more assertive and tough-minded, whereas females and laterborns tend to be more affectionate, tender-minded, and cooperative. Women tend to be conscientious, whereas laterborns do not, so these behavioral parallels do not apply across the board.

Birth-order effects are modified by age gaps as well as by the sex of siblings. The influence of birth order is muted when the age gap is so small that the relationship between siblings is nearly equal, and also when the age gap is so large that they do not compete for the attention of their parents. When middle children have a large age gap between themselves and their next older sibling, but a small gap between themselves and their next younger sibling, they are more similar to firstborns in their personality.

Although laterborns tend to be more socially liberal, as well as more adventurous and unconventional than their older siblings, there are exceptions to these generalizations that are attributable to other aspects of family dynamics. Firstborn children of socially liberal parents tend to become liberals themselves because they generally conform to parental values. A laterborn child of liberal parents may become a conservative just to be different. Furthermore, firstborns sometimes become social or political radicals because they are in conflict with their parents instead of identifying with them. Mao Zedong, the eldest of four children, was radicalized by conflict with his father, a cruel and tyrannical man who mistreated his wife, his children, and the workers on his farm. Mao once said that

there were two political parties in his family, and that he was the leader of the opposition. In general, laterborns are likely to rebel even if they do not have Attila the Hun for a father or the Wicked Witch of the West for a mother. They have elder siblings to induce them to identify with the underdog.

The consequences of birth order are often strongly dependent on the behavioral context, which is one of the most important moderators of human behavior. In different situations, the same person may behave quite differently, and the relevance of birth order likewise varies with the situation. For example, a firstborn may act in a dominant manner toward a younger sibling or a spouse, congenially toward peers, and in a subordinate manner toward authority figures – a behavioral style that constitutes a ‘pecking order personality.’

Social categories such as age, gender, and socioeconomic status entail standards of behavior that can influence personality. In connection with the study summarized in [Table 1](#), respondents assessed the personality of a close friend ($N = 1002$). Significant birth-order differences emerged, but they did so in interaction with other variables. Upper-class respondents, as well as older respondents, saw their best friends as exhibiting the traits generally expected by birth order. In contrast, college students – especially those from lower-class backgrounds – did not perceive these same birth-order differences. For example, college students did not describe their firstborn friends as being particularly conscientious or conventional, whereas older respondents did.

These seemingly contradictory results are best understood in terms of the attributes that are important for success within each socioeconomic class, and during different stages of life. College-age students, especially from lower-class backgrounds, are likely to prefer friends who are sociable and who know how to have a good time. Because firstborns are more socially assertive and inclined toward leadership roles than are laterborns, they respond to these behavioral norms by projecting a gregarious and outgoing ‘persona.’ When people graduate from college, take a job, and marry, they assume new life roles and greater responsibility. Within such older populations, birth-order effects in personality increasingly conform to the expected pattern. Firstborns, who tend to be more conforming than laterborns, are especially affected by such life transitions. Compared with other individuals, firstborns are significantly more variable in terms of how their personalities are perceived across the social categories of age, class, and marital status. The more responsibility and status firstborns have acquired – for example, by getting married – the more they are judged by their friends as manifesting a typical firstborn personality.

These findings make sense from the perspective of evolutionary psychology, which is also a form of social psychology. The personality traits that are typically associated with birth order develop in the service of competition for scarce resources, principally parental investment. Adolescent individuals do not generally command scarce resources, so their behavioral priorities tend to be different from those of adults. A firstborn who aspires to social approval may be dutiful at home (especially during childhood), agreeable and gregarious during adolescence, and competitive and self-disciplined as an adult member of the workforce. The expression of personality traits related to birth order is likely to be sensitive to these transitions

in the life course. In short, birth-order differences are not parent specific, but they are often situation specific. Research on birth order and creativity strongly reinforces this important conclusion.

Birth Order, Openness to Experience, and Creativity

As Robert R. McCrae has demonstrated, the various facets of openness to experience can be divided into two contrasting groups. One group reflects ‘intellect’ and is typified by adjective labels such as *intelligent*, *perceptive*, *curious*, *creative*, and *cultured*. The second group is defined by adjective labels that are closely associated with ‘nonconformist’ thinking, including *daring*, *unconventional*, *original*, *independent*, and *liberal*. Not surprisingly, the ‘intellect’ component of openness is more strongly correlated with IQ and years of education than is the second, or ‘nonconformist,’ component. Because firstborns tend to have higher IQs than laterborns, and because firstborns also tend to excel at academic pursuits, they are expected to express their creativity most strongly via openness in intellect. By contrast, laterborns are expected to express their creativity in ways that exemplify the nonconformist bent of their personalities.

Much of the existing research on birth order and creativity is marred by two shortcomings. First, investigators have generally failed to distinguish sufficiently between differing types of creativity; second, researchers have not usually studied creativity in real-life terms. In their monumental review of the birth-order literature from 1940 to 1980, Cécile Ernst and Jules Angst summarized the results of 28 relevant studies. 11 of these studies, which included such measures as the need for autonomy and the frequency of unusual word associations, showed no differences by birth order. The other 17 studies produced significant findings, but these results were largely contradictory. For example, three studies indicated that firstborns were more likely to prefer complex polygons (interpreted as a sign of greater creativity), whereas another five studies showed that laterborns preferred complex polygons. Even if these eight studies of visual preference had yielded consistent results, it may be questioned whether a partiality for gazing at complex polygons is diagnostic of creative achievement in real life. After all, a preference for parsimony and simplicity, not complexity, lies at the heart of modern science.

Research on divergent thinking is another area where birth-order findings have tended to conflict. Inasmuch as divergent thinking correlates substantially with IQ (a firstborn trait) as well as with unconventional thinking (a laterborn trait), this construct conflates these two different forms of intellectual ability. In fields such as literature, architecture, invention, and science, studies of creative achievement are generally limited by a failure to consider the nature of the creative act. It should come as no surprise that research in these various intellectual domains has generally yielded inconsistent results.

Some of the most compelling evidence for birth-order differences in creativity comes from intellectual and social history, especially in areas where the nature of the creative act is sufficiently public to be classified by experts in terms of differing forms of openness to experience. Considerable

research indicates that laterborns are more inclined than firstborns to change their views during times of radical political, social, or scientific change. This is because radical revolutions tap the nonconformist component of openness. During the Protestant Reformation, laterborns gave their lives to serve rebellion and firstborns to preserve orthodoxy. Laterborns were proportionately nine times more likely than firstborns to suffer martyrdom in support of the Reformed faith. In countries that turned Protestant, such as Henry VIII's England, firstborns were five times more likely than laterborns to become martyrs by refusing to abandon Catholicism. (These statistics are corrected for the greater number of laterborns in the population.)

The responses of scientists to radical conceptual transformations show similar differences. The Copernican revolution challenged church doctrine by asserting that the earth rotates around the sun. During the first half-century of this debate, laterborns were five times more likely than firstborns to endorse this heretical view. Nicholas Copernicus himself was the youngest of four children. George Joachim Rheticus, the young colleague whose zealous efforts finally prodded the 70-year-old Copernicus into publishing his unorthodox theory, was also a lastborn. In Darwin's own era, younger siblings were ten times more likely than elder siblings to become evolutionists. Darwin himself was the fifth of six children, as was Alfred Russel Wallace, codiscoverer of the theory of natural selection (Figure 1).

During other notable revolutions in science, including those led by Bacon, Descartes, Newton, Lavoisier, and Einstein, laterborns have been two to ten times more likely than firstborns to endorse the new point of view. This trend holds true even when the initiators of revolutions, such as Newton and Einstein, happen to be firstborns. Laterborns are more likely to endorse radical revolutions even after their scientific stance has been controlled for social attitudes (which are themselves a good predictor of the acceptance of such events). Accordingly, birth-order effects cannot be reduced to attitudinal

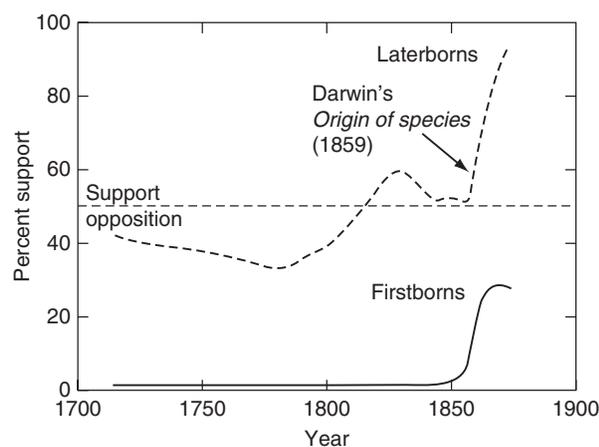

Figure 1 The reception of evolutionary theory from 1700 to 1875 by birth order ($N = 448$). During the long period of debate preceding publication of Darwin's *Origin of Species* (1859), individual laterborns were 9.7 times more likely than individual firstborns to endorse evolution. These group differences are corrected for the greater frequency of laterborns in the population. (From Sulloway, 1996, p. 33.)

differences, although birth order does influence social attitudes, which in turn influence openness to radical innovations.

Social Desirability Effects

Birth order exerts substantially more influence on behavior during radical revolutions than it does on self-reported personality traits, including those directly related to openness to experience. Radical revolutions typically constitute struggles over who controls valuable resources. It should come as no surprise that revolutionary challenges to the status quo provide a better test of personality differences (including those associated with birth order) than do self-report questionnaire data. In the study whose results are summarized in Table 1, firstborns claimed to be significantly more open to experience than their own younger siblings ($d = 0.16$, equivalent to a correlation of 0.08). But laterborns claimed to be even more open to experience than their own older siblings ($d = 0.33$, equivalent to a correlation of 0.16 in the opposite direction). The significant net difference between these two correlations strongly suggests that laterborns are more open to experience than are firstborns, despite firstborns' claims to the contrary. That the judgments of firstborns were generally incorrect about this aspect of their personalities is corroborated by their responses to an open-ended question. Subjects were asked, "What would your friends consider to be the two or three most unconventional or rebellious things, if any, that you have done during your life?" In answering this question, the number of words that respondents wrote down was significantly correlated with their total score for openness to experience. Relative to firstborns, laterborns tended to produce longer responses and to list a higher proportion of truly unconventional behaviors, as assessed by independent judges.

Other findings from this study reinforce the conclusion that social desirability influences self-reported judgments about personality. For example, older respondents believed that they were just as open to experience as younger respondents ($r = 0.00$). Yet these same respondents claimed that their siblings and friends were significantly less open to experience with age (mean-weighted $r = -0.14$). Both answers cannot be correct, and real-life evidence helps to arbitrate this issue. During radical revolutions, age is a reliable predictor of responses to change. As I have documented in a study of 121 major controversies in science and social thought, older individuals generally oppose radical changes (mean-weighted $r = -0.21$, $N = 4505$). In my questionnaire study, people appear to have correctly recognized in others what they failed to acknowledge in themselves, namely, a reduction in open-mindedness with age.

When we consider the fact that social desirability biases can produce correlational discrepancies as large as 0.3, and that most birth-order effects are about one third this magnitude, it becomes more clear why self-report data might tend to underestimate birth-order differences. On every dimension of the Big Five, social desirability effects dwarf those associated with birth order. Unfortunately, we cannot assume that such social desirability biases cancel themselves out with the use of direct sibling comparisons, because research has consistently shown that firstborns are more likely than laterborns to conform to social expectations. Because the degree to which

self-ratings are embellished in a favorable direction is probably different for firstborns and laterborns, it is difficult to know what is the true influence of birth order for any particular personality trait. For these reasons, real-life behavior remains the best test of the magnitude of birth-order differences in personality.

Age and birth order are only two of many significant predictors of individual responses to radical change. Being socially liberal is another substantial predictor. So is parent – offspring conflict, which disrupts birth-order effects among firstborns and makes them into ‘honorary laterborns’ in terms of openness to experience. Multivariate models that include these and other predictors of openness to radical innovation are significantly more powerful than predictions based on single variables. In general, people who are the most likely to endorse radical changes are also more likely than average to *initiate* such changes. Hence a willingness to endorse heterodox viewpoints is a necessary, but by no means a sufficient, condition for intellectual discovery. These findings do not mean that young people, laterborns, and social liberals have a monopoly on scientific creativity or truth. For example, laterborns run the risk of accepting new and radical viewpoints too quickly, just as firstborns run the risk of resisting certain kinds of necessary changes. Laterborns were nine times more likely than firstborns to support Franz Joseph Gall’s false theory of phrenology – the notion that character can be read by tracing bumps on the head. Firstborns correctly rejected this theory as pseudoscientific. (They also disdained phrenology because of its materialistic implications.)

During everyday ‘normal’ science, firstborns have a small but consistent advantage over laterborns. They are more successful academically and are more likely to become scientists in the first place. In addition, firstborns tend to win more Nobel prizes, which are generally awarded for creative puzzle solving (openness in the sense of ‘intellect’) rather than for revolutionary innovations (openness in the sense of ‘nonconformity’). Einstein revolutionized physics with his theories of special and general relativity. The Nobel Prize committee was wary of these theories and honored him instead for his discovery of the photoelectric effect. Owing to publication of the *Origin of Species*, Charles Darwin lost a knighthood that he had previously been slated to receive. A good indicator of a radical scientific revolution is the widespread opprobrium, not the accolades, that initially befall the instigators.

When scientific innovations involve ideologically conservative implications – as occurred, for example, with vitalistic doctrines during the seventeenth and eighteenth centuries – firstborns possess an even greater intellectual advantage over laterborns than they do during ‘normal’ science. Historically, firstborns have repeatedly championed new theories that bolstered God’s role in the Creation. Assessed jointly in terms of birth order and the ideological implications of innovations, four classes of innovation are possible, but only two have ever been documented. For example, laterborns have generally led radical revolutions, such as Copernicanism and Darwinism, that strongly challenged social and religious authority. Firstborns have generally backed innovations, such as eugenics and spiritualism, that also appealed strongly to religious and political conservatives. By contrast, there has never been an instance of a firstborn-backed radical revolution; nor has there ever

been a case of a conservative revolution that was advocated by laterborns and opposed by firstborns. In sum, the relevance of birth order to scientific innovation is strongly dependent on the nature of the innovation (Figure 2).

Birth Order and Achievement

Controlled for social class and sibship size, firstborns are overrepresented as scientists. Among laterborn scientists, middle children are particularly underrepresented, as they are among eminent individuals. These findings accord with the evidence that firstborns are more conscientious than laterborns, and that parents, especially under conditions of limited resources, tend to invest preferentially in firstborns and lastborns. On closer examination, evidence from the history of science indicates that firstborns and laterborns tend to achieve eminence in dissimilar ways. Firstborns have generally excelled in the physical sciences, where intellectual problems tend to be more clearly defined than in the life sciences. By contrast, laterborns have gravitated toward the biological and social sciences, where success often depends on knowing what the most important problems really are. The scientific achievements of laterborns have been facilitated by their tendency to pursue multiple research interests, a strategy that has been particularly fruitful within the life sciences where unsolved problems often transcend disciplinary boundaries. Charles Darwin distinguished himself in geographic exploration, geology, zoology, botany, ethology, and psychology. His knowledge of these diverse disciplines was crucial to his ability to develop his theory of evolution by natural selection.

Laterborns often achieve distinction in those walks of life that allow expression of their tender-minded qualities. For instance, laterborns are overrepresented among winners of the Nobel prize in literature and peace. Among participants in the abolition and Black Rights movements – who were mostly laterborns – middle children were the most likely group to employ nonviolent methods of persuasion. By contrast, firstborns and lastborns advocated militant strategies. During the French Revolution, firstborns such as Maximilien Robespierre rose to power within the National Convention by supporting the Reign of Terror. Younger siblings (particularly middleborns such as Georges Jacques Danton) opposed these extreme political measures and were ultimately responsible for the overthrow of Robespierre’s Montagnard (and largely firstborn) political party.

The relationship between birth order and creative achievement has not yet been studied with sufficient rigor for many intellectual domains, including music, art, literature, and business. When undertaking such future studies, researchers should bear in mind the differing kinds of openness to experience and their potentially distinct relationships with birth order. Studies also need to be controlled for other covariates – especially sibship size, social class, parent – offspring conflict, and social attitudes – that are required either for methodological reasons or because these variables moderate the influence of birth order. Ordinal position is only a proxy for differences in family niches (such as acting as a surrogate parent), and these proximate-causal mechanisms of personality development need to be investigated in greater detail. Finally, the nature of the behavioral situation is often a powerful moderating variable. In radical revolutions, birth-order effects tend to fade over time, as

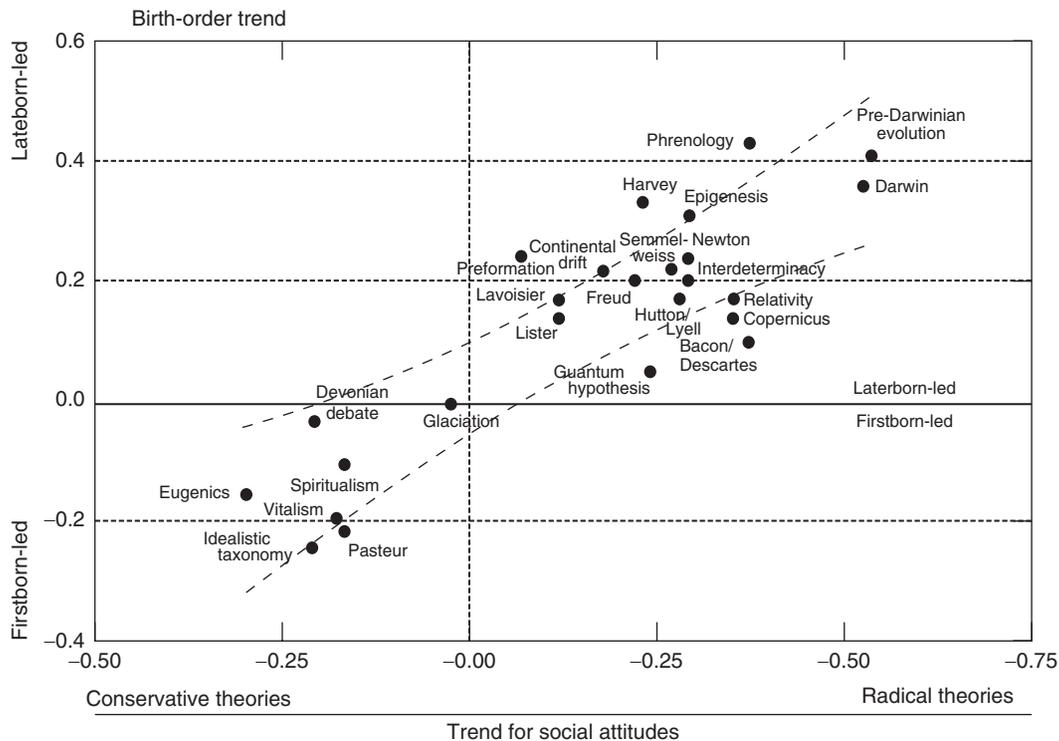

Figure 2 Birth-order effects in science, as they relate to the religious and political implications of 28 different innovations. The vertical axis depicts the correlation of birth order with support for scientific innovation ($N = 2013$). All events above the horizontal line (0.0) were endorsed by laterborns and opposed by firstborns, whereas all events below the line reflect greater support by firstborns. The horizontal axis indicates the correlation of social attitudes with support for each innovation. Events to the left of the vertical line (0.00) were endorsed by social conservatives and rejected by social liberals. Events to the right of the same line reflect support by social liberals and opposition by conservatives. Determinations of social attitudes involve more than 19 000 ratings made by expert historians, who judged the religious and political attitudes of participants in these 28 debates. The dashed lines indicate the 99% confidence limits for the regression line. This analysis establishes a simple generalization: *The more socially radical the innovation, the more it was supported by laterborns and opposed by firstborns*. Missing from the history of science are two classes of potential events. There are no radical revolutions that are backed primarily by firstborns, just as there are no conservative theories that are backed primarily by laterborns. (From Sulloway, 1996, p. 332.)

new and initially controversial ideas become more widely accepted. In addition, some new ideas are more controversial than others and tend to elicit correspondingly larger birth-order effects. National differences sometimes mediate these effects. Given their allegiance to Descartes' rival theory of celestial mechanics, French physicists – especially firstborns – manifested strong opposition to Isaac Newton's theory of universal gravitation. British scientists, including firstborns, welcomed Newton's ideas. Ultimately, the relationship between birth order and creativity needs to be approached in meta-analytic terms that include explicit roles for the nature of the innovation, as well as the social and intellectual contexts in which such innovations arise.

Conclusion

Birth order provides one important source of personality differences, which in turn underlie differences in creative achievement. Disparities in birth order cause siblings to experience the family environment in dissimilar ways. In addition, birth order introduces the need for differing strategies in dealing with sibling rivals as part of the universal quest for parental favor. This is a Darwinian story, albeit with a predominantly environmental twist. Siblings appear to be hardwired to compete

for parental favor, but the particular strategies they adopt within their own family are determined by the specific niche in which they have grown up. As children become older and leave the family, they modify their behavioral strategies – both competitive and cooperative – as they adapt themselves to new life roles. The enduring imprint of childhood learning, and its manifestations in adult personality, is nevertheless discernible in those abilities that come to us most naturally and that owe themselves to prior niche partitioning within the family. Through its context-sensitive relationship with birth order, creative achievement represents a case in point. Evidence from intellectual and social history highlights the conclusion that firstborns and laterborns do not differ in overall levels of creativity. Rather, brothers and sisters are preadapted to solving disparate kinds of problems, which they generally tackle using differing kinds of creative strategies.

Acknowledgments

For advice in connection with some of the research on which this article is based, I thank Paul T. Costa, Jr., Jerome Kagan, and Robert R. McCrae. I also thank two anonymous referees for their comments on an earlier draft of this article. This article was partially prepared while the author was Fritz Redlich

Fellow at the Center for Advanced Study in the Behavioral Sciences. I am grateful for financial assistance furnished by the Center's Foundations Fund for Research in Psychiatry and by the National Science Foundation (Grant SBR-9022192).

David Bohm 1917–1992

F D Peat, Pari Center for New Learning, Pari, Italy

© 2011 Elsevier Inc. All rights reserved.

David Bohm was a physicist and thinker who proposed an alternative approach to the conventional version of quantum theory, as well as proposing that a new *Implicate Order* lay behind what could be thought of as our surface perception of reality. Bohm's ideas extended beyond theoretical physics and included reflections on the nature or creativity and the order of society and the individual. He also proposed a dialog process where a group of 3–40 people would meet together over an extended period. This process has since been continued by a number of groups. While viewed in certain quarters as something of a maverick, his ideas remain influential.

Childhood

David Bohm's creative life involved a weaving together of many different threads and pathways, and so I will leave a discussion of Bohm's own views on creativity until the end of this article, where they will be seen to integrate with his life.

David Joseph Bohm was born on 20 December 1917 in the coal mining town of Wilkes Barre, Pennsylvania. His brother Robert was born four years later. His father Shmul Düm came from an orthodox Chasidic family in the Hungarian town of Munkács. He emigrated to the United States where an immigration official changed his surname to Bohm. Shmul worked at first as a peddler before settling in Wilkes Barre at the home of the Popky family, where he eventually married Frieda Popky and opened a used furniture store.

Bohm's childhood was not particularly happy. His father appeared distant and at times sarcastic to his eldest son while his mother began to show increasing signs of mental disturbance. It was left to David's maternal grandmother to run the household. The young boy was physically uncoordinated and remained on the fringes. While his school companions played together, he would wander away in the woods. While home life was less than ideal he discovered the world of science fiction at the age of ten when he came across the magazine *'Amazing Stories.'* Soon his imagination was fired with visions of aliens and space travel. Always those other worlds and their inhabitants proved far more ideal than the Earth he had left behind. Soon the boy was composing stories of his own and writing to the editors of his favourite science fiction magazines.

He also began to have compelling fantasies of light so intense that it would penetrate matter and probe his own brain. Soon he was carrying out scientific experiments and became enthralled by such things as the gas fluorine that could etch glass and the metals potassium and sodium that would ignite in contact with water.

David did well at school, particularly in mathematics and, after reading a story about a boy who threw a ball into the fourth dimension, began to work out the geometrical consequences of a four-dimensional world. This caused him to wonder if the world around him was less substantial than

people believed and to speculate that maybe we were all living in a higher dimensional reality. Dreams of ideal worlds and higher dimensions may well be the childhood seed out of which his *Implicate Order* was later to develop.

With a home that was chaotic, oppressive, and at times violent, David had a desire to seek security. This extended to his own body – he would carefully plan each physical movement when, for example, climbing a tree, so that he was always in control of his body. One day his friends were crossing a river by means of a series of rocks. As usual Bohm planned out each move, but as he jumped onto the first rock he realized that he could only continue to cross by being in constant movement, rather than moving between a set of fixed positions. This appears to have been an important revelation to him; to learn that security could lie in movement. Later, in the world of his physics, Bohm would focus on the notion of 'holomovement,' or movement of the whole. Thus in Bohm's mature view, the electron itself was no longer a particle but a process that constantly unfolds and enfolds out of the *Implicate Order*.

Towards the end of his time at high school Bohm was reading about Niels Bohr and developed his own approach to quantized orbits by proposing that the electron has tides and that the interval between successive tides is equal to the time the electron takes to orbit around its nucleus. He was also working on a 'general theory of the cosmos' which would also include the existence of mind.

Bohm and Oppenheimer

After high school Bohm studied physics at Penn State University where he felt free to pursue his own studies, and then at Cal Tech, where he became unhappy because of the amount of coursework that was demanded. Bohm already realized that his creativity lay in following his own pathways. A friend suggested he should speak to J. Robert Oppenheimer who had established a school of theoretical physics at Berkeley. The interview went well and Bohm was offered an assistantship that would cover his living expenses. Later in his life Bohm was to become friendly with the psychiatrist, David Shainberg, who noted that Bohm had always been in search of approval and in particular from one who could act as a father figure. Oppenheimer at first appeared an ideal person to fulfil that role; however, in addition to his somewhat arrogant attitude Oppenheimer had what he called his 'beastliness.' This behavior pattern involved drawing a new student very close to him and then suddenly rejecting him leaving the individual hurt and confused. Bohm's rejection was to come later.

Oppenheimer gave Bohm his first research problem, a theoretical description of proton–deuteron scattering. Bohm had already established his characteristic mode of research which involved taking long walks so that he could think. After several months he was invited to give a seminar on his work and for

two days prepared his talk, working up a great 'charge of mental energy.' The talk went so well that he reached the point where he began to feel that he had moved from physics into something almost mystical, so that the individual consciousness of the audience had been transcended and the room was filled with intense light. A psychiatrist would probably diagnose that Bohm had experienced a psychic inflation, and indeed the inevitable letdown was a period of depression that lasted for a year.

Transformation of Society and the Individual

Ironically under the Manhattan project Bohm's work was classified and so, without clearance, he was not even in a position to defend his Ph.D. thesis! External forces were also at work in other ways. Bohm had earlier been concerned about the rise of Nazi Germany and the anti-Semitism he had noted in his own country. Now he learned about the Soviet Union and read Marx and Engels. He had always been concerned about the fragile nature of human society but it now appeared that, through dialectic materialism, society could change in a radical way and that, within such a new society, the individual would also transform. But, Bohm wondered, how could there be individual freedom within the collective, a question that was to resonate with his next research topic, the theory of plasmas in metals. It was a particular characteristic of Bohm's life and creativity that his scientific, social, and personal concerns were always part of a greater whole.

Plasmas in Metals

A plasma is a gas of electrically charged particles and can be found, for example, in the sun. But plasmas also exist in metals since, while most electrons are bound to the atoms in the metal lattice, the outer electrons are free to move through the charged lattice. Bohm established his theory by using two sets of variables; one described the movement of individual electrons, the other the collective motion of the plasma. By expressing a relationship between the two sets of variables Bohm was able to obtain an accurate theory of plasma behavior in a metal. What is more, while the electrical repulsion between two electrons normally falls off quite slowly – meaning they can feel this repulsion at great distances – in the case of the plasma this repulsion falls off rapidly. Bohm's conclusion was that to the extent that the individual contributes to the collective, that individual becomes relatively free.

The United States was now at war and Oppenheimer was essential to the running of the Manhattan Project. However the security services were uneasy with his left-wing sympathies and he was subject to investigation. When questioned, Oppenheimer was willing to name names and discuss his students' political sympathies. One of those whom he termed 'politically suspect' and possibly 'dangerous' was David Bohm. It would be some years before Bohm learned that his father figure had betrayed him. Not having security clearance for the Manhattan Project Bohm moved to Princeton where he developed a strong friendship with Einstein. He continued his work on plasmas but also began to write a text book on quantum theory, one that would present a clear expression of Bohr's Copenhagen interpretation.

Quantum Theory

The original quantum mechanics was created by Heisenberg, and a year later an alternative wave mechanics approach was proposed by Schrödinger. However it was necessary to give a coherent interpretation of these theoretical advances. This was done by Bohr in Copenhagen in discussions with Heisenberg, Schrödinger, Pauli, and others. In particular they discussed the 'meaning' of the theory, which Heisenberg proposed lay in the mathematics itself. But Bohr pointed out that when physicists discuss equations they use ordinary language which contains all manner of assumptions about space, time, and causality. His conclusion was that physicists are 'suspended in language' and that attempts to define the ultimate nature of quantum reality would end up running into paradox and confusion.

Hidden Variables

Bohm began to see that in a certain sense Bohr's approach was almost tinged with mysticism. Bohm believed for dialectical materialism to work, matter must be rational all the way down to the subatomic, yet Bohr seemed to be saying that there is a limit to what can be said about the quantum world. Inevitably Bohm felt the need to create a totally realistic causal account of the subatomic world. His theory is often referred to as 'hidden variables' and suggested that in addition to the ordinary electrical potential experienced by an electron there was a new 'quantum potential' at work. It is this quantum potential that is responsible for all the new features of the quantum world.

While engaged in this research Bohm was summoned before the House Un-American Activities Committee where he refused to name names. On 4 December 1949 he was arrested on a charge of Contempt of Congress and went to stand trial in Washington. While he was acquitted he had already been forbidden to set foot on the campus of Princeton University. Despite being the leading expert on the theory of plasmas, Bohm could find no university position in the United States or Europe, and therefore his only option was to move to the university at São Paulo in Brazil; and so his period of exile began.

Exile

This exile coincided with the publication of his 'hidden variable' paper. Bohm had expected it to create a stir of controversy and initiate debate on the quantum theory but, with the exception of de Broglie and Pauli, the world of physics ignored him. It was only later that Bohm learned that Oppenheimer had organized a seminar on Bohm's paper at Princeton. Oppenheimer's aim had been to discover a flaw in the theory, but when this could not be done he announced that "if we can't disprove Bohm we must all agree to ignore him."

Bohm moved to Israel where, with Yakir Aharonov, he discovered an effect whereby an electron is affected in a region where the electrical and magnetic field is zero. While the Aharonov-Bohm effect was controversial at times, it soon demonstrated that nonlocality was an essential feature of the quantum world. Later, several experimental groups were able to demonstrate that parts of a quantum system that had

initially been entangled together remained correlated even when separated by many meters. Of course ordinary systems can remain correlated by exchanging signals, limited by the speed of light, but nonlocal effects did not involve the exchange of signals. Bohm met his wife in Israel, a British medical volunteer named Sara Woolfson.

A New Order for Physics

In 1957 Bohm moved to England to take a position in the theoretical physics department at Bristol University. At Bristol Bohm focused on the inconvenient fact that, despite several decades of hard work, physicists been unable to reconcile quantum theory with Einstein's relativity. For Bohm this was not simply a matter of requiring a clever addition to a theory, or applying new mathematics, but rather proof that a radically new 'order' was required in physics. In 1957 Bohm wrote *Causality and Chance in Modern Physics* in which he offered an alternative to quantum theory.

The development of Bohm's approach to this new order for physics also gives some clues to the nature of his creativity, which was never narrow, nor focussed in one channel. Bohm had become engaged in a long correspondence with an American artist, Charles Biederman who had written *'The New Cézanne,'* a book that discussed Cézanne's desire to find a new order in art, one that would combine all the discoveries of the Impressionists with the rigor of a Poussin. Through this correspondence Bohm learned of Cézanne's approach and, in particular, how within each part of the canvas is implied the whole, and the whole is implicit in each of the parts. How much of this Bohm consciously absorbed is not clear; however he was now on the way to creating his own notion of an *'Implicate Order.'*

In a sense this notion goes back to Bohm's school day visions that the universe in which we live is only a part of something much larger; maybe, he thought, one of higher dimensions. The world of well defined objects in space and time, described by classical physics, Bohm termed the *'Explicate Order.'* Behind this order lies something deeper, the *Implicate* (or *enfolded*) *Order.* As aspects of the *Implicate* unfold they appear as the *Explicate.* This means that elements that are far apart in our *Explicate* world are in fact intimately connected and enfolded together within the *Implicate.* By way of an analogy Bohm compared a normal photograph, where points that are distant from each other on a person are also distant on the photograph, with a holograph where each part on the image of the person is enfolded over the entire holograph so parts distant on the figure are folded together in the holograph. Break off a part of the holograph and the entire figure can still be seen, admittedly with less definition.

Krishnamurti

Bohm's long term associate, Basil Hiley, suggested that Bohm's thinking was like a helix. He would focus on some particular concern or theory then appear to move away to some other area of thinking but eventually return to his starting point but in a more advanced way of thinking.

Thus while one area of focus remained the *Implicate Order,* with hidden variables very much in the background (but to return later), another was to begin a series of discussions with Jiddu Krishnamurti. In his general reading he had learned of the teacher Krishnamurti who had been discovered as a boy by Annie Besant and brought up to be the next great World Teacher. A meeting was arranged between the two men and at one point, when Bohm used the word 'totality,' Krishnamurti jumped from his chair and embraced him. A strong relationship soon developed between them – Bohm became a trustee of the Krishnamurti school at Brockwood Park.

Bohm believed that Krishnamurti's physical brain was unique in that it was not subject to the normal conditioning of other people, but could remain silent and free from thought so that something else could operate. He also felt that this mutation of his brain could also occur within himself when he was in the presence of Krishnamurti and that this change was permanent. While he had earlier pictured the transformation of the individual via the transformation of society, he now believed that a personal transformation was possible through Krishnamurti.

Their discussions together were audio taped and later some of these were transcribed for publication. Bohm took these discussions so seriously that he once remarked to me that maybe he should give up physics in order to focus all his energies on the exploration with Krishnamurti. Bohm also continued these investigations on his own, and was exploring such areas as the relationship between thought and the physical body, in which the property of proprioception would extend to thought itself. He told me, "I have seen some of the things Krishnamurti talks about. I have looked at reality and seen that it is an illusion."

He was also exploring the role of language and the way in which the subject-verb-object structure of European languages reinforces the Newtonian world view of well defined objects in space interacting via forces and fields. Later this interest inspired him to develop what he termed the *'rheomode,'* or *flowing mode,* an artificial language rich in verbs that he felt would be appropriate for a discussion of the quantum level.

The Quantum Potential

Bohm moved to Birkbeck College, University of London where he collaborated with the physicist Basil Hiley. One of Hiley's students, Christopher Philippides, read Bohm's earlier *'hidden variable'* paper and used a computer program to calculate the shape of the quantum potential, as well as the paths taken by electrons in the famous *'double slit'* experiment.

Seeing these electron trajectories was a revelation for Bohm and he plunged back into physics and what he now termed *"the ontological interpretation of quantum theory."* The shape, or *'form,'* of the quantum potential was quite detailed and was an expression of the experimental surroundings experienced by the electron. It was in fact *'in-form-ation'* about the experimental background, and the electron was responding to this information in selecting its particular path.

While the effect of the potentials of everyday physics – electricity, magnetism, or gravity – depend on their size, the

effect of the quantum potential depends on its 'form.' This implies, Bohm argued, that the electron is able to 'read' this information so it possesses 'proto-mind.' The seeds of mind, in Bohm's opinion, had been present from the very beginning.

In parallel with this work, and his investigation of the nature and limits of thought, Bohm was also looking at what he termed 'pre-space' – the underlying structure out of which space-time and matter emerged. In collaboration with Basil Hiley he was using noncommutative algebras, in particular those of Hermann Grassmann and William Kingdon Clifford. This work continued until Bohm's death and was pursued by his colleague Hiley, who made a major breakthrough in 2008.

Clearly Bohm's creativity covered a wide spectrum with different preoccupations informing and enhancing each other. His interests included mathematical work in theoretical physics, his search for new orders in physics, his concern with thought and the nature of consciousness and its relationship to the physical body, as well as the transformation of the individual and society, and the relationship between language and our conception of reality. Again the theme of wholeness was ever-present. Since mind and matter could not be separated he preferred to use the term signa-somatic and soma-significance to express their essential unity.

He returned again and again to the theme of fragmentation. Fragmentation for Bohm involved not only taking apart what properly belonged together, but also attempting to put together what did not belong together. He found fragmentation not only in the discipline of physics, but in many other fields of knowledge and within society itself. Naturally when he chose a title for his next book, published in 1980, it was '*Wholeness and the Implicate Order*.'

In 1980 Bohm experienced chest pains and was found to have two blocked coronary arteries with a third almost blocked. The result was a by-pass operation, but after the operation Bohm's blood pressure collapsed and he was in a coma for two days.

Creativity

Following Bohm's recovery he began to work with me on a book, '*Science, Order and Creativity*,' a task that gave me some direct insight into his creativity and method of working. I would arrive at his Edgware home in London for morning tea and we would then read over the notes I had made the previous day. The next step was to go for a walk together, for Bohm thought best while walking, and discuss the material we had already written and explore new ideas. This would continue over lunch until it was time for his afternoon rest. For the remainder of the afternoon I would make notes on our discussions. At times Bohm would become animated about a new idea which seemed to appear to him as a whole gestalt which he then felt he had to explain and explore as fast as possible. Sometimes what he said did not seem to make sense, but this did not appear to matter to him since he was attempting to sketch out the wider pattern of how all this fitted together. And so the notes I made appeared to reverse a position or even appear contradictory. But all that would be discussed on the following morning during our walk together.

Dialog

Bohm's investigations with Krishnamurti had been among the most important encounters of his life but now he began to have concerns that Krishnamurti was not giving attention to the tensions that were arising at the Brockwood Park and Ojai schools. He also felt that the nature of his discussions with Krishnamurti were not as fruitful as they had been in the past and he decided to confront his friend while on a trip to Ojai in the spring of 1984. This did not go well and it appeared that a break was developing. Around the same period Bohm was becoming increasingly depressed and consulted a Jungian analyst. The therapy was not fruitful and he turned to a Freudian, Patrick de Mare.

In addition to one-to-one therapy, de Mare also worked with encounter groups. De Mare felt that such groups could play a positive role in social therapy and suggested that early hunter-gatherers, who travelled in groups of thirty to forty, would engage in regular discussions of this nature and so deal with any problems or tensions that came up. Despite his mental agony Bohm was attracted to de Mare's theory for it offered the possibility of transformation. Earlier he had believed that transformation would come via a Marxist revolution of society, then through a mental transformation in the presence of Krishnamurti. But now he saw yet another possibility, transformation via dialog. One weekend, during a visit to a group hosted by Peter Garret and Donald Factor, Bohm proposed that they attempt to move towards a dialog. Soon he was running dialogs in Israel, Sweden, Denmark, Geneva, and the United States as well as a regular group in London.

According to Bohm each of us has one or more 'non-negotiable' positions and when we encounter a person with the opposite position we either avoid that area, or risk rupturing the relationship. However within the group there will always be some who take an intermediate position, and their presence can help to slow down a person's reaction. Faced with a harsh word or unpleasant idea we tend to react quite rapidly with a feeling of internal bodily discomfort, a gesture or word. But if this can be slowed down then we will begin to develop a felt understanding of how all of this is structured within the body. Thanks to proprioception we know the location of our hand when we cannot see it, but now Bohm saw that through dialog people could develop a form of proprioception for 'how' they think.

Yet another function of the group is in regard to language. Language had always been of great importance to Bohm and he felt that it had become 'polluted' by the manipulation of politicians and other special interest groups who used language in specialized ways. Dialog, he believed could help 'clear up the pollution' in language.

The Super Implicate Order

Bohm was also extending his notion of the *Implicate Order*. Aspects of the Implicate unfold and manifest as the Explicate. But in this sense there was nothing new emerging, since all was already copresent in the *Implicate*, and so Bohm proposed another level – the *Super Implicate*. When the *Implicate* manifests an aspect of itself into the *Explicate* this manifestation is

observed by the *Super Implicate*, which then feeds back into the *Implicate*. By way of an illustration Bohm pointed to a video game. The computer program (*Implicate*) unfolds into the *Explicate* (the screen with the spaceships) and the whole process simply iterates. But with the addition of a player it is possible to observe the spaceships and, by moving the joystick, to feedback into the computer and modify the program. In this way, Bohm said, creativity is introduced.

Bohm also met with me at the Bailey Farm Institute near Ossining, New York to discuss our next book. Initially it was to be called *'The Order Between'* but in our discussions we touched on the notion of mediation, that was often used as a way of resolving disputes rather than arguing them in court. Bohm suggested that this approach could lead to compromise and an 'order between' was not always the best solution. What was needed was an 'order beyond.'

By 1991 Bohm's arteries began to clog again and his depression was more severe. By May of that year he confessed that he was feeling suicidal and was admitted to the Maudsley Hospital in London where he was given a course of 14 bilateral ECTs. Following this treatment he was released from the hospital at the end of August and put on a course of cognitive therapy. While he did appear to be cured of his depression he was troubled by memory loss, and his colleague Hiley noted that he did not have the same energy with which to engage in their research in physics.

Bohm and Language

The following spring Bohm visited Ojai in California and then the Fetzer Institute in Kalamazoo, Michigan where he had been made a Fetzer fellow. This coincided with a circle of Native American elders and Western scientists. The meeting was important to Bohm for several of the participants spoke the strongly verb-based Algonquin family of languages and they discussed their world view of constant flux and change. Bohm had long considered the role that a verb-based language would play in the way we perceive the world, and was now able to see it in action and in particular held a number of discussions with Leroy Little Bear of the Blackfoot confederacy.

Later that year Bohm was diagnosed as having suffered a heart attack and was also treated for viral pneumonia. On 27 October, while working at Birkbeck College he telephoned his wife to say he would take the underground back to Edgware and from there a taxi home. 'You know it's tantalizing,' he said, "I feel I'm on the edge of something." By the time the taxi arrived at his front door he was dead.

Bohm on Creativity

Creativity for Bohm was something innate. There was no need to 'foster' or 'encourage' creativity, but rather to avoid the blocks that prevent it from operating naturally. During his undergraduate years he had been happiest and felt most creative when he was free to pursue his own reading and explorations. Yet later, when he attended Caltech, he became depressed with the demands of the curriculum, the constant problem solving and quarterly examinations. At that time the only pleasure he obtained from physics came from his own independent reading

of Dirac and Eddington. Indeed Bohm believed that one of the serious blocks to creativity arises out of the educational system itself. He noted that when children are praised or rewarded for their work, the nature of their learning changes from that of free creative play into seeking rewards or avoiding punishment. In this way, Bohm felt, creative energy is diminished.

On one occasion Bohm had been offered a fellowship in one of the Oxford colleges. He made an informal visit, looked at the portraits hung on the walls of the dining hall and remarked "too much tradition." He did not accept the fellowship. Similarly he felt that conventional education gives too much weight to authority and fixed knowledge. This in turn can lead to a lack of self confidence. Above all what is required is a free play of the mind: one that can throw up new perceptions. Yet he also acknowledged that it is necessary to retain a sensitive perception towards the role of certain forms, for example to the structures of a fugue or sonnet.

And as to creativity within science? The mind has a tendency to hold on to what is familiar and this includes the tacit infrastructure of science, a tendency of thought which extends outwards into society at large. Bohm was aware that, with the discoveries of quantum theory, Niels Bohr had devoted his energies to establishing the orthodox 'Copenhagen Interpretation' of the theory. In his own work Bohm would not accept this orthodoxy and for some physicists he was seen as something of a maverick. Likewise he viewed the conventional approaches to seeing a unity between relativity and quantum theory as simply involving 'new mathematics' or 'new ideas' while his own vision was that a radically new order to physics was required. Bohm felt the present state of affairs was a result of individual scientists lacking the courage and energy to examine the whole structure of science. In turn, such an attitude encourages fragmentation whereby a topic can be studied in a more limited context. In particular, he felt that while the great scientific figures of the early decades of the twentieth century had been interested in philosophy, most contemporary scientists did not bother to explore the metaphysical assumptions of their positions.

Bohm also felt that a scientific discovery can be equated with a poetic metaphor, such as 'all the world's a stage.' To see the world and a stage as being the same is to exercise a radical perception of the mind. For Bohm this would be accompanied by great creative energy. An example from physics is William Hamilton and Carl Gustav Jacobi's discovery during the nineteenth century that it is possible to describe the movement of material bodies not only via traditional Newtonian mechanics but also in terms of waves. Thus the scientific metaphor becomes 'the particle is the wave.'

It is well known that visual perception is an intentional act involving the overall disposition of mind and body. Bohm himself was aware of the role of the body in the creative nature of his scientific perceptions. For example, while working on some equations he experienced a combination of movements within the body. He remarked on this to Einstein who told him that he would squeeze a ball while working on the field equations of general relativity. And just as perception involves not the mind but also the body, perception within science takes place not only within the mind but also within a larger social context. For this reason communication is important; not only in terms of an internal dialog but also at the social

level. Indeed Bohm argued that perception and communication cannot be fragmented but form a whole – ‘perception-communication.’ This was yet another area in which creativity had become blocked. As with other professions, such as law and medicine, science uses language in specialized and restricted ways. It was Bohm’s feeling that during the twentieth century communication in science had become compromised in subtle ways to the point where at times it was almost incoherent. He argued, for example, that differences in the way language was being used had led to the breakdown in communication between Einstein and Bohr, two scientists who had earlier dialogued extensively. Likewise he felt that the tensions between Heisenberg’s and Schrödinger’s approaches to the quantum theory had been resolved too rapidly. If those tensions had been allowed to continue then a new creative insight could have emerged. In short, it was Bohm’s view that science has to be carried out in a radically new way. He often would say that the aim of science should be the desire “to pursue truth no matter where it takes us.”

Glossary

Electroencephalography (EEG) EEG represents the electrical activity recorded along the scalp produced by synchronous firing of groups of neurons within the brain.

Emergenesis A process whereby novel or emergent properties arise from the interaction of more elementary (and partly genetic) properties.

Functional magnetic resonance imaging (fMRI) fMRI measures neural activity based on relative changes in blood flow and oxygenation in the brain.

Neuroanatomy Neuroanatomy is the study of the structural and anatomical organization of the brain.

Neuropsychology Defined narrowly, neuropsychology is the study of brain lesions and their effects on mental function. Defined broadly, neuropsychology is the study of correspondences between brain structure, mental function, and behavior.

Introduction

Creativity is an emergent trait. A trait is deemed emergent if its expression is brought about by the *simultaneous* presence and *interaction* of a set of constituent factors (e.g., intelligence, mental flexibility, working memory, etc.). In turn, many of creativity's constituent factors have been shown to have biological bases, supported by genetic, neuropsychological, and neurobiological evidence. In this article I shall review empirical evidence that sheds light on the neural underpinnings of the constituent components of creativity. I shall do so in relation to (a) the neuroanatomy of creativity; (b) the neurobiology of creativity in relation to *task-independent* resting-state brain activity; and (c) the neurobiology of creativity in relation to *task-dependent* cortical function. First, however, I shall begin with a description of the conceptual framework that motivates this neuroscientific approach to studying creativity.

Hierarchical Model of Creativity

Much like other higher-order mental activities such as reasoning and planning, there appears to be no unitary brain 'module' for creativity. In contrast, at the brain level complex higher-order mental activities appear to be based on distributed networks, built upon component neural systems that are reconfigured dynamically in relation to task demands. In this sense the neural architecture of creativity is clearly hierarchical. An important feature of complex hierarchical systems is that they tend to be 'nearly decomposable' into component systems. This means that under certain circumstances scientists are able to isolate and study the components of interest within larger complex systems.

A hierarchical functional organization for complex systems makes sense from an evolutionary perspective because it is more efficient for the brain to reconstitute component systems to serve multiple complex activities than it would be to create separate systems for each complex activity. For example, given that cognitive inhibition has been shown to be an important process in both reasoning and creativity, it would be advantageous to engage the same brain system to serve inhibition in

both mental activities. In fact, the same prefrontal system known to underlie inhibition is engaged in both mental activities. This approach has demonstrated that higher-order mental activities that appear different at the 'macro' (i.e., behavioral) level (e.g., creativity, reasoning, planning, etc.) are frequently built on largely shared cortical infrastructures at the 'micro' (i.e., neural) level. To the extent that one is capable of isolating the relevant structural and functional components of this architecture, one can use knowledge gained in one domain (e.g., reasoning) to test hypotheses in other domains (e.g., creativity).

Given that this hierarchical approach is based on the isolation and study of component factors, the key question to ask at the outset involves what those factors for creativity may be. Although currently there is no agreed-upon set of component factors that are individually necessary and jointly sufficient for creativity, most researchers agree that creativity is influenced by the interaction of a host of social, developmental, cognitive, and emotional factors. However, given that mental processes – conceptualized as cognitive processes and structures – are considered to be the "essence and engine of creative endeavors," my focus here will be on the neural underpinnings of *cognitive* factors relevant to creativity. Where appropriate, to the extent that they shed light on cognitive processes and structures, I shall also discuss the relationship between self-report measures of creativity and brain structure and function. Given the nascent state of this field, some caveats exist. For example, most studies have involved small sample sizes and await replication. Furthermore, most studies have mapped a single cognitive process (e.g., novelty detection/perception) onto a single measure of brain function, based primarily on functional magnetic resonance imaging (fMRI) or electroencephalography (EEG). Nevertheless, some convergence can already be noted across studies; a necessary requirement for the emergence of a preliminary cortical model of creativity. I shall end by noting what some of those points of convergence may be.

Neuroanatomy of Creativity: Cortical Structure

Structural imaging studies of the human brain have shown a moderate correlation between total brain volume and

psychometric measures of intelligence ($r=0.3$). However, recently there has been a trend toward focusing less on total brain volume and more on cortical thickness within specific brain regions. This is because developmental studies have demonstrated that the trajectory of the thinning of the cortex within frontal and parietal cortices constitutes an index of maturation for brain organization. Specifically, studies have shown that among children cortical thinning is fastest in those with the highest level of intelligence. However, cortical thinning does not occur at the same rate or stage throughout the brain. For example, while the parietal lobes exhibit the most thinning in early adolescence, the frontal lobes exhibit the most thinning in late adolescence. Although currently the nature of the underlying cellular events causing variation in cortical thickness are unknown, one possibility is that the formation and usage-dependent selective elimination of synapses may help sculpt the neural circuitry that underlies or supports cognitive abilities. This is consistent with movement away from plasticity toward usage-dependent specialization and efficiency in development.

Armed with this knowledge, Rex Jung and colleagues tested the hypothesis that creativity in young adulthood is related to cortical thickness. Associations would be evidence of the degree of linkage between creativity and maturation for brain organization. While the correlations between creativity and cortical thickness have been shown to form a complex pattern, here I shall focus on the link between creativity measures and cortical thickness in the right angular gyrus. In structural and functional studies this region has been associated repeatedly with intelligence, and hypothesized to play a role in the formation of (distant) semantic associations necessary for abstraction and understanding metaphors. Given that creative people have been shown to be faster in judging relatedness between concepts regardless of modality, the involvement of the right angular gyrus is evidence of its potential role in associational processes in creativity. Importantly, creativity measures have been linked to higher and lower cortical thickness depending on the brain region, suggesting that to the extent that cortical thickness constitutes an index of maturation for brain organization, higher creativity is not always linked to more maturation. Furthermore, despite focus on the right angular gyrus here, the associations have occurred in both hemispheres, suggesting that creativity is not a right-hemisphere syndrome, as previously believed. While interest in the link between neuroanatomy and creativity is not new, studies investigating this issue constitute a necessary step toward building a converging biological model of creativity, as has been shown to be the case with intelligence.

Neurobiology of Creativity: Resting-State Brain Activity

The four-stage theory for the creative process involving preparation, incubation, illumination, and verification, is well known. Insight – defined as the sudden appearance of a solution to a problem that one has been working on without any conscious sense of progress – has been historically linked with illumination, especially following transition from the incubation stage. However, the role ascribed to insight in creativity is

complex, ranging from central to irrelevant. The majority view suggests that insight is a small but necessary component of the creative process. Note that this description is consistent with a view of creativity as an emergent trait where individual components are necessary but not sufficient for the expression of the trait. This view opens up the door to studying insight as a component of the creative process.

Although the focus of this section is on *resting-state* brain activity, the empirical journey begins with task-dependent brain activity. John Kounios and Mark Jung-Beeman have conducted the most systematic series of studies on the neural correlates of insight solution. Given that so-called ‘insight problems’ can be solved either analytically or with insight, coupled with the fact that subjects can reliably judge which of the two processes led to the solution, retrospective verbal reports on a trial-by-trial basis have been used to categorize solution strategies. Two general sets of findings characterize this line of work. First, EEG evidence has shown that activity corresponding to insight solutions is associated with a burst of high-frequency activity (i.e., 40-Hz gamma-band) in the right anterior temporal lobe starting about 300 ms prior to indicating that a solution had been found. The corresponding fMRI signal has been localized in the right anterior superior temporal gyrus, located underneath the electrodes showing the EEG effect. The involvement of the right anterior temporal lobe has been linked to a weakly activated problem solution, in line with the role of this region in semantic association. Second, prior to the burst of gamma-band EEG activity in the right anterior temporal lobe a burst of slower activity (i.e., 10-Hz alpha-band) has been measured over the right occipital cortex. This activity has been linked to ‘sensory gating’: given that alpha-band oscillations are the brain’s dominant rhythm and reflect idling or inhibition of brain areas, activity in right occipital cortex could reflect a reduction in the amount of visual information passed from visual processing areas to higher areas that perform more abstract computations with that information. Therefore, insight solutions are believed to occur as a function of the weak activation of a problem solution in the right anterior temporal lobe coupled with sensory gating in the right occipital cortex that enables the subject to report it.

A reasonable question to ask is whether it would be possible to find the source of insight solutions even further back in time by examining brain activity *prior* to the display of each problem. In other words, brain activity already present upon the display of a problem may bias cognitive processing, increasing the likelihood of either insight or analytic problem solving. For problems solved by insight, EEG has revealed greater neural activity over the temporal lobes of both cerebral hemispheres. This activity has been attributed to the priming of brain areas that process lexical and semantic information, a function ascribed to the temporal lobes. Furthermore, insight problems have been shown to be associated with activity originating in the anterior cingulate. This area is involved in error monitoring, attention switching, and cognitive control. In this context its involvement has been attributed to readiness to detect and switch to weakly activated solutions.

Having demonstrated that brain activity at the time immediately prior to a solution can distinguish between analytic and insight solutions, a natural next question to ask is whether such dissociation can be linked to resting-state brain activity prior

to engagement in the task altogether. In fact, it has been shown that subjects who are more likely to solve problems with insight exhibit more right-hemisphere activity (and/or less left-hemisphere activity) relative to low-insight subjects in the low-alpha, beta-2, beta-3, and gamma bands under eyes-closed and eyes-open conditions. The involvement of this region is consistent with the view that solution of anagrams is facilitated by the formation of remote or loose associations between ideas, given the right hemisphere's role in the processing of remote associates. It appears that individual differences in resting-state brain activity influence the deployment of specific cognitive strategies for problem solving. It is known that resting-state EEG is fairly stable and has a genetic basis, further suggesting that fundamental properties of the nervous system can have far-reaching influence over components of creative thinking. Furthermore, given that personality traits such as extraversion have been associated with individual differences in resting-state brain activity and with creativity, findings linking resting-brain activity to creativity raise the intriguing possibility that resting-state brain activity may underlie those individual differences in personality that are linked to creativity. This possibility remains to be examined.

Neurobiology of Creativity: Task-Dependent Brain Activity

Having discussed the link between task-independent resting-state cortical activity and creativity, I shall now turn my attention to discussing studies of task-related cortical function. This section will be organized based on three component processes of interest: divergent thinking, mental flexibility, and the detection/perception of novelty.

Divergent Thinking

Divergent thinking has long been viewed as an important component of creative problem solving. The Alternate Uses Test is one of the most popular divergent thinking tasks. Early EEG results from pioneering studies by Colin Martindale distinguished alpha wave activity in relation to engagement in the Alternate Uses Test from activity in relation to engagement in the Remote Associates Test and intelligence tests. These three tasks vary in the extent to which performance is a function of reliance on divergent versus convergent processes: whereas the Alternate Uses Test is generally perceived to be a relatively 'pure' measure of divergent processes, the Remote Associates Test is considered to depend both on divergent and convergent processes, and intelligence tests are perceived to depend primarily on convergent processes. Highly creative people exhibited the greatest variation in EEG alpha wave activity across the three tasks. Specifically, whereas low-creativity subjects exhibited low EEG alpha on all three tasks, high-creative subjects exhibited high EEG alpha only during work on the Alternate Uses Test. Given that alpha wave activity is an inverse measure of cortical activity, this finding confirms that creativity is linked to task-related variation in cortical function.

Recently, Andreas Fink, Aljoscha Neubauer and colleagues have employed the Alternate Uses Test to study brain activity using EEG and fMRI in the same study design. Converging

methodologies is important because EEG and fMRI, due to their greater temporal and spatial resolutions respectively, offer researchers different types of information and thereby a more complete picture about task-related brain function. When EEG data were analyzed along the lower (8–12 Hz) and upper (10–12 Hz) alpha frequencies, the results demonstrated that the generation of unusual uses in the context of the Alternate Uses Test is associated with greater alpha synchronization in lower and upper bands compared to a task in which subjects were instructed to think of typical characteristics of conventional everyday objects. Greater alpha synchronization was especially prevalent in frontal areas of the brain. Interestingly, when subjects were categorized based on the originality of uses generated in the context of the Alternate Uses Test, those with higher originality scores showed greater synchronization in the right than left hemisphere. However, predictably, a different picture emerged from fMRI data. Specifically, the Alternate Uses Task activated a left-lateralized network comprising the inferior frontal gyrus extending to the supplementary motor area and anterior cingulate. This network is frequently activated in linguistic tasks, and its involvement is not surprising given the verbal nature of the stimuli and the task. This indicates that the characteristics of the task are reflected in the activations perceived in imaging technologies. This should sensitize researchers to task features when interpreting imaging results.

Another classic divergent thinking task is Match Problems. Unlike the Alternate Uses Task, Match Problems is a visuospatial problem-solving task. Whereas some match problems can be solved by a sequence of generate-evaluate cycles, others involve start states that create strong mental sets that implicitly obstruct certain transformations. For this reason it has been argued that good performance on Match Problems necessitates 'set shifts.' By relaxing the constraints placed on the problem space, set shifts effectively widen the problem space. Furthermore, set shifts are facilitated by mental representations of the start state that are more abstract and ambiguous than the one provided in the problem statement. This enables subjects to remain noncommittal about solution paths and strategies while flexibly generating potential moves.

Laurie Miller and Lynette Tippett studied the neural architecture underlying the solution of Match Problems in patients with focal brain lesions. Their results have shown that patients with focal right frontal lobe lesions were impaired specifically on those match problems that required set shifts. This selective impairment was especially apparent in patients with lesions to right *ventral* (as opposed to dorsal) prefrontal cortex (PFC). This deficit has been attributed to the role of the right frontal region in permitting flexible strategy shifts. These neuropsychological results have been corroborated with fMRI data. Specifically, Vinod Goel and Oshin Vartanian have shown that whereas engagement in Match Problems was associated with activation in left dorsal lateral PFC and right ventral lateral PFC, the latter structure was activated exclusively when subjects successfully solved problems that required set shifting. The convergence of neuropsychological and imaging results provides strong support for the role of right ventral lateral PFC in flexible strategy shifts in the context of Match Problems.

Some Match Problems allow the generation of multiple solutions to the same problem. Divergent thinking is relevant here because it reflects the ability to generate many solutions to

a problem or prompt (i.e., fluency). In the context of Match Problems, activation in right dorsal lateral PFC has been shown to covary parametrically with the number of generated solutions. There are at least three possibilities for its involvement in divergent thinking ability. First, generating additional hypotheses in divergent trials requires their maintenance in working memory. The involvement of right dorsal lateral PFC in working memory for maintaining and storing information is well established. Second, as subjects generate and evaluate hypotheses, they need to keep track of successful and unsuccessful attempts. On a cognitive level, one would expect a positive correlation between the number of hypotheses generated and the demand on monitoring resources and relations. In fact, right dorsal lateral PFC has been implicated in tasks that require the integration of multiple relations and monitoring subgoal processes, as would be required here. A third possibility involves conflict resolution. As additional solutions are generated, not only is there a need to update previous responses, but also to resolve the conflict between responses. As one generates more responses, the conflict of choosing between multiple responses would increase accordingly. The role of the right dorsal lateral PFC in conflict detection and/or resolution is widely recognized. Of course, these three explanations are not mutually exclusive, and possibly all contribute to divergent production.

Mental Flexibility

One of the hallmarks of creativity is mental flexibility. Mental flexibility is best conceptualized as the ability to relax the constraints within which a problem is embedded, in turn facilitating exploration of multiple possibilities. This idea was alluded to earlier in the form of 'set shifting' in the context of Match Problems, but it will be discussed more focally here. The concept of mental flexibility is intricately linked with the concept of attention. Specifically, recent experimental evidence by Vartanian and colleagues has shown that creative people are more variable in their focus of attention, focusing and defocusing attention as a function of task demands. Specifically, when the problem space is relatively ambiguous, the search for solutions is aided by relaxing the constraints placed on the problem space. This increases the likelihood that seemingly irrelevant information may enter the focus of attention, potentially providing the building blocks for a solution. Under such conditions attention is more defocused in creative people. In contrast, when the problem space is relatively unambiguous, performance will benefit by increasing the constraints placed on the problem space, bringing into focus only those building blocks that have been selected as relevant for a solution through further elaboration. Under such conditions attention is more focused in creative people. This variability indicates that creative people are cognitively more flexible than noncreative people.

Early studies by Martindale relied on EEG to investigate the link between flexibility in attention and cortical activity. Consider story generation. This activity consists of two phases: a phase in which the subject thinks about the story to be written (inspiration phase), and a phase in which the subject writes the story (elaboration phase). Given that creative subjects are more variable in their focus of attention, they should only defocus attention during the inspiration phase of story generation, as reflected by lower cortical activity. This is precisely

the observed pattern of results. Interestingly, creative subjects exhibited lower cortical activity in the inspiration phase only when they were told to be as creative as possible, but not otherwise. This indicates that creativity is associated with defocused attention when appropriate but not otherwise, offering further evidence for cognitive flexibility in creative subjects.

More recent studies have experimentally manipulated task constraints and observed the neural correlates using fMRI. In the context of an anagram task conducted by Goel and Vartanian, the results have shown that right ventral lateral PFC is responsive to variations in the constraints placed on the problem space. In fact, activation in right ventral lateral PFC varies parametrically as a function of the constraints placed on the problem search space. This is consistent with results from Match Problems showing that right ventral lateral PFC is sensitive to the level of constraints placed on the task, and has a role to play in mental flexibility. It is also consistent with results from the reasoning literature indicating this region's responsiveness to indeterminacy in structure of arguments.

Novelty Detection and Perception

Creativity is commonly defined as the generation of novel and useful products. However, novelty is only meaningful in relation to the context within which it is measured. Hence, in experimental settings statistical frequency (i.e., unusualness) is used as a useful proxy measure for novelty. Recently, fMRI studies have investigated the neural correlates of novelty by studying the formation of unusual semantic associations. This process is relevant to creativity because the ability to observe associations between seemingly unrelated concepts can function as an engine for novelty within the creative process. Although the paradigms vary across studies, they frequently involve the presentation of a prompt (e.g., noun) following which a response must be generated (e.g., verb). By explicitly instructing subjects to generate either the first word that comes to mind or a word that has an unusual relationship with the word, experimenters can use the logic of cognitive subtraction to elucidate the neural correlates of unusual word generation. Carol Seger and colleagues have shown that the generation of unusual verbs activates an extensive network in the right frontal lobe, specifically in the superior and middle frontal gyri, with medial frontal activation extending into the anterior cingulate. The involvement of the right frontal lobe is attributed to its propensity to process distant semantic associations, which could in turn function to form novel associations. There is evidence to suggest that the right hemisphere encodes information at a different level of granularity than the left hemisphere. Specifically, the right hemisphere encodes information at a more 'coarse' level than the left hemisphere, which could in turn function as a mechanism for generating novelty by facilitating the formation of novel associations. This is consistent with recent views that both hemispheres can process the same information in different ways, updating the classic hemispheric specialization emphasis from modality (verbal, spatial) to process.

Points of Convergence

Although as a field the neuroscience of creativity is not sufficiently mature for the emergence of a full-fledged biological

model, certain points of convergence have emerged. First, at the level of brain structure, it has been shown that cortical thickness is linked to creativity in both hemispheres, although the direction and strength of the correlations can vary as a function of cortical regions and instruments used to measure creativity. This is analogous to saying that creativity is related to maturation of brain organization. A large amount of literature has linked maturation of brain organization, as measured by cortical thickness, to intelligence. The extent to which cortical thickness shows similar patterns of correlation for creativity and intelligence can offer insights about shared variance between creativity and intelligence at the level of brain structure, and thus offer clues about hypotheses to be tested subsequently at the functional level.

Second, recent evidence suggests that there may be a link between resting-state brain activity and insight solutions, and that this link may be moderated by hemispheric asymmetry and individual differences in the ability to generate insight solutions. Equally important, this finding has emerged within a research program that has generated consistent findings in terms of the involvement of the right anterior temporal lobe in insight solutions. There is a good deal of evidence to point to the role of this region in the formation of distant semantic associations because of the tendency of the right hemisphere to engage in coarse coding of information. Given the link that exists between resting-state brain activity for various personality variables linked to creativity (e.g., extraversion), this program of research could form the basis for substantiating the link between stable individual-difference variables and creativity.

Third, to the extent that creativity benefits from flexible strategy shifting, there is now converging evidence from lesion studies, EEG, and fMRI to suggest that the ventral lateral aspects of right PFC may be mediating the perceptual and conceptual constraints necessary for strategic flexibility in problem solving. Of course, the ventral lateral aspects of PFC bilaterally play a critical role in regulating inhibition. Given that constraint mediation requires inhibition, the responsiveness of the ventral lateral aspects of PFC to task constraints may be embedded in its more general role in regulating inhibition.

Summary

Perhaps one of the most enduring myths in psychology has been to view creativity as a right-hemisphere syndrome. The facts do not support this view. On the contrary, the evidence reviewed here demonstrates that the neural system underlying creativity is distributed, with structures located in the right and left hemispheres serving specific and varying components of the creative process. The current view is the product of the theoretical (and related methodological) approach used to study the neural bases of creativity – conceptualizing it as a

componential and hierarchically organized mental activity. As suggested by Goel, such an approach to studying higher mental function is consistent with evidence from the natural sciences, design, and engineering suggesting that hierarchical organization is “a deep fact about the world.” Given the success this approach has had in shedding light on other higher-order mental activities, there is reason to believe that it will pay dividends for understanding creativity as well. Eventually, however, it will be necessary to study the interdependencies of the component processes. This will require an integrative theoretical framework to motivate studies of how the components within the larger system interact.

*THE BRONTË SISTERS, taken as a collective, constitute the leading English novelists of the 19th century. The three sisters and their brother, Branwell, grew up in the small Yorkshire town of Haworth, children of the local curate. From very young ages, all exhibited a precocity for writing and drawing that was fueled by their mutual interest and need. Although writing in relative obscurity for a major portion of their brief lives, nevertheless, all three sisters had a major impact on the English novel and therefore on world literature. Charlotte's character of Jane Eyre constitutes the earliest example of the independent woman in literature—resourceful, introverted, and clear in her standards and values regardless of external influences. Charlotte's portrayal of women as independent personalities was manifested through a forceful personal narrative style that established her as one of the most brilliant novelists of her time. She is compared favorably with Thackeray and Dickens, and the only female writers from that period who rivaled her were Eliot, Austen, and her own sister Emily. Emily's *Wuthering Heights* provides a brilliant depiction of human passion played off against the wilds of nature and the inevitability of fate. Her juxtaposition of the locale of the moors, so deeply known to her, with the hatred and revenge instincts of her characters provides an intensity rarely found in fiction of any era. Her style of first person narration, outside of a traditional time sequence, also presages more modern techniques. Anne's work, beside Charlotte's and Emily's, appears rather bland, yet her quiet piety seeps through in the use of prose and revealing language in both her novels. Choosing the vocation of governess and the setting of the moors, she combines two of her sister's novelistic devices yet emerges*

*with her own original style in both *Agnes Grey* and *Tenant of Wildfell Hall*. While more muted than her sisters' works, Anne's contributions have been assessed as being major in their own way, and thus fulfilled her strong desire to do some good in the world before she left it, as noted by Chitham's 1991 biography of her.*

The Early Life

The Brontë sisters in childhood shared solitude and seclusion, intelligent companionship, and intense family affection that also manifested itself in a love of animals. Struck early by family tragedy in losing a mother before Charlotte was six, and two older sisters shortly thereafter, the remaining children turned inward and to each other for survival and comfort. Tutors by their scholarly father from early ages and surrounded by stimulating books and magazines, the Brontë children lived in a created world. They reveled in a mysterious supernatural force fueled by the engravings of John Martin, the plays of Shakespeare, the writings of Byron and Sir Walter Scott, and the naturalistic setting of the Yorkshire moors. The Brontë children shared an important perspective on the power

Portrait of Charlotte Brontë. Used with permission from CORBIS/Historical Picture Archive.

of creation. They created the imaginary worlds of Gondal and Angria, using Patrick Brontë's gift to Branwell of toy wooden soldiers as the stimulus for imaginative story development. The children created a language for the soldiers, a cartography of their landscape, and whole plays that gave the soldiers life. These intensely romantic influences in childhood affected the Brontës throughout their lives, always seeking for and finding excitement in the ordinary.

Charlotte, Anne, Emily, and Branwell were all precocious and voracious readers from an early age as well as young practicing artists, pursuing assiduous copying of drawings that interested them, especially Bewick's woodcuts of British birds. The Brontë children also were well versed in history and the politics of the day, appropriating leading British figures for their plays and debating the motivations of such figures. Charlotte at age 14 drew up her list of life's works, an impressive 22 volumes, and exhibited a strong knowledge of literary form. Not only did the early reading, drawing, writing, and family discussions serve to stimulate the Brontës' imagination, it also provided intensive practice in literary and artistic traditions.

The Tapestry of Work and Life

The Brontës have attracted substantial scholarship about their lives and works. They have been the subject of multiple biographical studies, and have left substantial personal writings to be analyzed by scholars. They were also prolific in their published manuscripts, leaving enough work to trace the development of form, style, and content. In the case of Charlotte Brontë, even her juvenilia, the 22 little books she wrote in collaboration with her siblings, constitutes a separate area of study, still being deciphered by scholars.

The Brontës are an excellent example of writers not formally shaped by educational institutions. Modern writers can learn their craft through school and college programs, special seminars and workshops, and formal mentors, but none of these opportunities were available to the Brontës, who led sheltered lives mostly in the context of family. Social context and the historical period in which they lived also may have limited their talent development based on issues of gender and, with the Brontës, class as well.

Like other women of their respective historical periods, the Brontës lived with their birth family or at least nearby. The Brontës never lived anywhere else but Haworth during their entire lives except for one year in Brussels for Charlotte and less time for Emily.

Family provided the basis for friendships, education, and financial and social support. As a result, each writer was geographically grounded as well, accounting for the strong use of "place" in their work. Pollard cites Charlotte from her letters of a bleak Haworth: "No other landscape than a monotonous street—of woodlands, a grey church tower, rising from the center of a churchyard so filled with graves that the raxes weed and coarse grass scarce had room to shoot up between the monuments".

The intellectual quality brought to bear in their work is consonant with the internal influences seen in other studies of creative people. Committed to a vision of an ideal, they worked on a statement of meaning. For the Brontës, the ideal

conveyed a sense of justice for their female characters. Underlying all of their work was the curiosity to explore new forms and meanings and the concomitant persistence to work hard and alone, absorbing themselves in writing for long periods of time.

Overexcitability, an extreme desire to engage the personality in certain types of experiences, in intellectual, emotional, and artistic dimensions of their lives, was very apparent from an early age. The Brontës were described as high-strung, fascinated by ideas, and interested in the artistic domain all their lives. A nervousness, possibly of genetic origin, strongly affected both Branwell and Charlotte. While both were outgoing and exuberant, they were prone to overstimulation.

Branwell is said to have had a nervous breakdown while away at school, therefore accounting for his father keeping him closer to home. His overwrought tendencies tinged with romanticism led to his ultimate humiliation and demise at the hands of his tutee's mother, whom he adored and who would reveal his weakness toward her; Branwell's boyhood was viewed as self-indulgent, in manhood leading him to an addictive lifestyle culminating in an early death in 1848.

For the Brontë children, the act of creating stories and sharing them with each other built a closeknit partnership of the imagination wherein each child became a character and wrote from that perspective over a period of 16 years, according to Spark's 1993 review of essays. It was, however, the quality of emotional sensitivity that fueled their work, and transmitted that feeling into art. And clearly for each of them, real talent and insight were present in their ways of expressing meaning in written form.

According to Alexander's 1991 work on the analysis of the Brontë juvenilia, this juvenilia is the best record we have of the development of writing genius. More importantly, this early work was the basis for all of Brontës' adult work. The particular gift that allowed them to survive as leading writers of the Victorian period lies in their intensity of expression, and their ability to describe with powerful detail the settings, feelings, and the natural world that their characters inhabit. These qualities originated in childhood as a game of Gothic-type motifs for the Brontës to amuse and confound each other.

Great poetry and great art served as major influences on the Brontës' aesthetic sensitivity and creative bent. All of the Brontës painted and used visual art as an adjunct to their writing. Each worked diligently at illustration, exhibiting substantial powers of conceptualization though limited skill in execution. Gaskell notes in her biography of Charlotte, and later Emily, that the sisters were particularly interested in painting and the works of great artists as growing children. For example, Charlotte drew up a list of painters whose works she wished to see by age 13. Moreover, the painstaking reproductions of all three sisters helped to develop important skills of observation and analysis needed to become great novelists. They were especially fond of John Martin's engravings of lost cities of the ancient world, for they awakened in the Brontës a feeling for imagery corresponding to their appreciation of Byron's poetry.

The central motivating theme for all of the Brontës' works is a sense of justice for that which is morally and ethically right. She and her siblings had richer imaginations, greater drive,

and more intellectual energy than other Victorians of the time, setting them apart from peers. The Brontës were also highly conscious of the role that writing played in their lives, stating that work was a wonderful companion. Through the assertiveness of Charlotte, all three women's work was published under the male pseudonyms of Currer, Ellis, and Acton Bell, only later to be revealed as written by women living in a remote area of the country.

For their time, the Brontës could also be considered feminist writers, especially Charlotte. From her early juvenilia to her mature novels, her female characters are vividly portrayed. In fact, all of the Brontë sisters' novels were considered too raw at first publication because of their passionate intensity and portrayal of women rebelling against the social norms of the times.

The Brontës' continual quest for the real behind the conventional in female characters marks them as the most important fictional writers of their time on the plight of women, as noted by the recent biographies of the sisters by Frasier and Barker.

Charlotte Brontë in particular strove to overcome her sheltered experience in the act of writing by contemplating feelings or experiences related by other people until she was able to understand and describe them in writing. In a letter to a publisher, included in Gaskell's 1992 biography, she noted, Is not the real experience of each individual very limited? And, if a writer dwells upon that solely or principally, is he not in danger of repeating himself, and also becoming an egotist? Then too imagination is a strong, restless faculty which claims to be heard and exercised.

The Brontë sisters possessed a mental initiative that allowed them to compensate for and overcome limited experiences in the world.

Relationship to Creativity

Evidence for the development of their creativity focuses on several variables, cited in VanTassel-Baska's 1998 chapter on creativity, all of which the Brontë sisters exhibited deeply. Informally, the Brontës developed the facilitating processes necessary to create original products in a given domain, such as fluency, a flair for novelty, insight and intuition, use of imagery, and an ability to use metacognitive strategies effectively. Their early childhood preoccupations clearly enhanced these process skills and honed them to high levels for use in adulthood. Their internal factors of creativity include intelligence; such personality variables as openness, intensity, and nonconformity; psychoticism; and mental energy. The Brontës all possessed these qualities and exhibited them in life as well as in their work. Their external factors of creativity include the powerful role of educational variables, strong family values that support the work, and the social-cultural context. While not all of these were favorable to the Brontës, by sheer perseverance their creativity prevailed over limitations in education and social environment. The role of the family was a strong positive influence on the development of the Brontës as artists. Not only was their father a strong intellectual and moral force in their lives, but they were each other's influences as supporters and critics of their evolving writing talents.

Personal catalysts for the Brontës that spurred them to creative heights appeared to include the adversity of coping with early deaths in the family of two sisters and a mother, the isolation of Haworth and the parsonage, their individualistic natures, and the natural setting of the Yorkshire moors.

Using life material as subject matter for character models and lived experience in the natural world, the Brontës evolved a unique form of communication for their period and in the process lived a creative life of the mind.

Glossary

Accounting/finance An organizational department that tracks monetary flows and maximizes its utilization for organizational purposes.

Business A process by which the exchange of currency, goods, and services takes place. Business is also used as a synonym for the organizations engaged in these exchanges.

Creative industries A collection of organizations involved in similar businesses whose main output is considered to be creative in nature. Such industries include the film, music, publishing, and video game industries.

Culture The norms, values, and world view held in common by organizational members.

Free/open source software Software made available under conditions where the user can freely access, redistribute, and alter the software's underlying code.

Leadership A management function concerned with developing and setting organizational goals, motivating workers, and controlling work flows.

Management The process by which businesses are led and controlled.

Management information systems (MIS) A business function for facilitating the flow, storage, and use of organizational data.

Marketing The organizational department that scans the environment for new business output opportunities, advertises existing products, and develops channels for product delivery.

Research and development The organizational department that creates new products and processes to produce these products.

Slack Organizational resources not specifically committed to firm operations, and therefore available for application to unanticipated needs.

Total quality management A business process used to reduce output defects and continually increase product desirability.

The Role of Creativity in Business and Management

Some people see a disconnection between business and creativity. This point of view characterizes businesses as rigid hierarchies that stifle individual creative development and hinder societal creativity. The reality is much different for many organizations where creativity and business/management have enjoyed a long-standing symbiotic relationship. This article will discuss the many ways this relationship has manifested.

Business can be defined as a set of activities that facilitate the exchange of desired goods between parties. Usually these activities occur through organizations developed to facilitate this exchange; but business can also be conducted between individuals or between individuals and organizations. Business transactions are usually performed by ongoing organizations with formal designs and structures, or such transactions may also occur through ad hoc collectives with short-term durations (such as farmers' markets). Often the terms business and businesses are used synonymously (as they will be used in this article). Business is also used as a synonym for profit seeking activities, but business also can occur in nonprofit settings.

As with the term business, management has many definitions. The word, however, has a generally agreed upon meaning that will be used in this article. Management is coordinating activities between individuals, resources, and organizational systems to complete business and organizational operations. Management has various interrelated activities designed to control organizations in achieving goals and objectives. Management is responsible for providing vision, setting goals, and developing and implementing strategy. Management is also responsible for coordinating, motivating, and directing the

individual's work; an aspect that is strongly linked to – though separate from – leadership.

An Historical Perspective

To better understand the modern relationship between business and creativity, an historical perspective is needed. There is a long tradition of wealthy and powerful individuals providing patronage to creative artistic works. Examples of such support include wealthy Greek merchants, the Catholic Church (especially during the Renaissance), and Chinese and Japanese emperors. Such patronage usually took the form of these entities commissioning artists to create works glorifying an idea the patron wished promoted or the patrons themselves. While creative works were produced independent of this system, most enduring pieces from the ancient world come from this patronage system. When economies changed to a more capitalist approach, artistic support switched from patronage to market-based structures – artists would present their works to the broader public, and this public would fund future creative endeavors by purchasing existing works. In time, businesses and even whole industries emerged to facilitate the development and distribution of artistic works to a wide audience.

As a counterpoint to businesses' artistic support, business relies on creative ideas to advance and find new markets. Indeed, all business started as a creative idea about conducting transactions. Modern business itself resulted from a series of creative ideas developed and shaped by cultural forces. These ideas have led to such institutions as stock exchanges, advertising, corporations, and restaurants. Businesses also rely on creative ideas for the technologies they employ to remain

competitive and produce goods and services. They use creative ideas to develop new products, delivery channels, marketing methods, financing ideas, and new management methods.

Creative ideas are also important in improving existing management and business processes, for example, routing packages or handling customer complaints. This type of innovation is called garden variety, or everyday creativity and generates incremental progress. Such advancement, however, may eventually lead to larger changes in business processes.

Business/Management's Role in Advancing Creativity

Organizations provide many services for creative endeavors including providing distribution channels for musicians, writers, artists, and other creative workers. Businesses also made inexpensive personal computing a reality, and with this technology new creative vistas opened up for large segments of society. Continually dropping computer hardware prices and free or inexpensive creative software give many people the tools necessary for making music, developing electronic paintings, photographic manipulation, and even creating and editing movies. These new tools provided a creative flowering that could not have been imagined even a decade earlier.

The business environment can also set conflicting possibilities for creative endeavors. For example, with the Internet's emergence distributing creative ideas and products has become much easier. Individuals can send their work worldwide for little or no cost through digital mediums. This technology allows independent artists such as musicians, writers, artists, and film-makers to reach self-sufficiency for the first time. However, businesses continue to act as artistic output gatekeepers. For example, Apple's iTunes store determines which artists have an outlet for selling their work in that venue. While the new distribution channels hold the promise of greater artistic opportunities, it is unclear how far the public is willing to search for new talent instead of relying on existing gatekeeper organizations to vet artistic work.

Social networking, which has become a valuable business in itself, has facilitated new ways of bringing creative work to people's attention. There is also You Tube where videos of all kinds can catch on with the public and go viral. The first movies based on a You Tube video success are currently in production.

One final point needs to be addressed in this introductory section. While this entry attempts to cover creativity in all its business and management aspects, most creative work within organizations is termed innovation. Innovation is purposeful creativity: creativity designed to solve some problem or issue. While the wider term will be mostly used, the narrower term is what actually more commonly occurs in firms.

This article will provide more details on how creativity interacts with the business environment by first giving an overview of management and creativity, then business as a whole, a discussion of creative industries, and a recap with future possibilities for the business/management-creativity link.

Management and Creativity

Scholars and practitioners have devoted great efforts into examining this relationship between management and creativity.

By 2010, over 1100 scholarly articles and books had been published on management creativity. While it is impossible to distill this knowledge corpus into a document of any reasonable length, there is some information about the management-creativity link that most interested parties should know. These areas are as follows: organizational environment, culture, and structure; leadership; teams; and individual worker characteristics.

Organizational Environment, Culture, and Structure

An organization's environment is singularly powerful in shaping an organization's creativity. The environment influences how creative the organization must be to succeed, and thus directs and limits how much management can influence organizational creativity. In general, turbulent and uncertain organizational environments require greater organizational creativity. Organizations increase their creativity – both in output and internal processes – to meet greater competitive demands in a turbulent environment. There is also a Darwinian effect in that less creative organizations tend to fail in turbulent environments, thus leaving more creative organizations to continue competing.

Partially due to environmental forces, certain industries have more creative organizations than others. Newer industries tend to be more creative than established industries. Thus the computer industry is more creative than the flour industry. Also, more competitive industries – those with no dominating set of organizations – tend to have more creative organizations.

An organization's culture is the greatest influence and predictor of creativity. This culture is largely set by the founder, and it is difficult to change once established. Subsequently, it is important to understand how cultural characteristics relate to organizational creativity. A major cultural factor is process (a focus on production methods) or outcome orientation (a focus on end results), with process oriented organizations tending to lower creativity. In addition, firms that promote individual flexibility tend to have higher creativity levels.

Specific organizational structures and characteristics can also foster and support worker creativity. Increased organizational slack and decreased hierarchy increases creativity. Firmer communication channels increases creativity for individual members and teams. Rewarding creativity increases creative behavior but the corollary is that workers must be protected from negative sanctions for unsuccessful creative attempts. A fear of punishment for attempted creativity results in diminished creativity.

Organizational social networks also play an important role in workplace creativity. Ties to more creative workers increase worker creativity, thus potentially creating a virtuous cycle of increased creative output from all involved. However, strong social ties can also inhibit creativity among creative-class workers (workers trained for and with jobs focusing on creative output). For typical workers, it appears that a moderate number of ties may be best for increasing creativity. Too small a number limits the number of ideas a worker is exposed to, but too many may create information overload or introduce a form of peer pressure that limits creative development.

Management must consider these points when designing an organization's structure. Businesses have little control over

their environment, and culture can be too difficult to change – therefore organizational structure becomes one of the best controllable factors for improving organizational creativity. Structures can also be altered to maximize organizational creativity during environmental changes, and may have such useful side-effects as channeling worker dissent into creative modes of organizational support. Some companies during difficult times found creative ways to keep workers on the payroll through having them do jobs done formerly by temporary workers or paying them to do volunteer work. Instead of angry laid – off workers, they developed a community of loyal employees.

Leadership

Top organizational leadership provides the vision for directing creative efforts. This vision channels (and thus limits) creative output, directing what types of creativity are accepted in an organization. This unified vision also allows organizational members to work in the same direction, thus promoting greater collaboration and creative advancement. Organizational leaders should provide an expansive enough vision to promote worker creative input, but clear enough for all members to agree on common goals. Top leaders also must ensure that their creative vision has the potential for profitable outcomes. Additionally, this vision determines how creativity is valued.

Leadership plays an important role in promoting individual creativity. As with strategic leadership, leaders provide direction for how individuals channel creative energies through one-on-one interactions. Information is emerging on specific leader behaviors such as how transformational leadership promotes creativity, though workers must also be intrinsically motivated for this leadership style to be fully effective. Additionally, over controlling leaders will decrease their subordinates creativity. Individually supportive leadership is especially effective when combined with appropriate worker mood states and a positive work context. This context is created when leaders provide an atmosphere of justice, trustworthiness, and developmental feedback. Leaders should also provide workers with more direct support for creative activities such as encouragement, guidance, and resources necessary for increasing workers' creative output.

Teams

Business creativity most often arises in teams. Team based projects help spur creativity through member skill sharing – an individual rarely has all necessary skills for a particular creative endeavor. Rather, different team members make unique contributions to the work. Teams also allow idea exchange between members and promote information flow and new idea generation. However, some team climates and structures promote more creativity – both for individuals and teams. For example, individual creativity is highest in learning oriented teams. Individual creativity is also enhanced when there are other creative individuals in a team. Increased specialization heterogeneity will increase team creativity, though teams need a transformational leader to maximize this effect. Perhaps most counterintuitive is that process standardization can increase creativity. This may be because – as with leader

vision – worker creativity is channeled into specific tasks. When properly structured, organizations can create teams that are very fertile arenas for developing new ideas.

Team climate can play a crucial role in creativity by facilitating an open exchange of ideas between members, and providing a support system for these members. Team members must be rewarded for their creative work.

Individual Workers

While organizational and team characteristics greatly influence a worker's creative output, individual characteristics also play a role. Worker intelligence is highly and positively related to creativity. Research indicates that the type of intelligence also plays a role in creativity. Workers who employ visual thinking are more creative than nonvisual thinkers.

Human resources becomes important for developing a firm's creativity through the selection and training of the most creative individuals available as organizational needs develop and change. In order to maximize organizational creativity, the human resources function must be strategically integrated into all organizational creativity plans.

Areas of Business Creativity

Creativity is a vital part of all organizational functions. This section will provide specifics about creativity's role in Research and Development, Knowledge Management, Advertising and Marketing, Quality Management and Information Systems, and Finance and Entrepreneurship.

Organizational Research Output

Research and development (R&D) is by its nature a very creative process. Firms use R&D to generate new products, processes to make these products, and internal procedures for better performance. In most organizations special teams or departments are responsible for R&D. While R&D is usually a fairly directed process, many prominent firms have policies that promote dispersed R&D across workers. For example, Google and 3M expect all professional workers to spend a certain portion of their time working on their own ideas for new products.

Patent production is a visible firm creativity output. Patents are state sanctioned, time-limited monopolies on new ideas given to encourage transforming creative ideas into tangible commercial output. Therefore, they can be seen as a proxy for organizational innovation. While not all patents are turned into products, most organizations pursuing their development have strong incentives to finalize the ideas into marketable output. Patents also provide a public good beyond the encouragement of new commerce.

By requiring that invention specifics be openly published in patents, the public can capitalize on and freely reproduce inventions after the patent's expiration. The health care sector has especially benefited from this system with the generic drugs. Large pharmaceutical companies and academic institutions spend billions of dollars a year to develop new drugs.

In turn, these creating organizations recoup their cost by manufacturing or licensing high cost drugs. After patent expiration, other manufacturers can use the formula from a patent, manufacture a generic version, and provide low cost alternatives to more expensive brand name pharmaceuticals.

Knowledge Management

Business knowledge management is both a source and outcome of creative work. An understanding of this business functions' importance has increased in the past few years, and it continues to increase in value. Knowledge management's focus is to go beyond simply retaining organizational data such as sales records, to developing an understanding of what the data mean, and how it can be used more effectively. It includes developing organizational memory and cultivating expertise in using existing organizational wisdom to improve operations. Good knowledge management relies on workplace creativity in order to find better ways to foster knowledge creation and development. In turn, firms with better knowledge management systems will have greater intellectual resources to promote and evaluate creative output.

Research indicates that knowledge management provides a coordinating mechanism for organizations that enhances innovation and overall productivity. However, the way knowledge management is implemented also plays a role. Unless the knowledge management system is implemented to exchange information throughout an organization, only local knowledge pools will develop. This limitation will hamper innovation, and thus fail to spark the creativity levels needed by businesses. Studies have also indicated that many different knowledge management methods are equally effective for enhancing innovation – it is not so much the specific type of knowledge management system implemented as how many different practices are put into place.

Advertising and Marketing

Advertising is the organizational creative form that most people imagine when they think of creativity. This makes sense since we are exposed to advertising through radio, magazines, newspapers, television, and the web. Some of these advertisements can display amazing creativity, with audiences often more appreciative of advertising contents than the show itself. The constant creative changes in the use of media such as TIVO and the Internet has forced companies to become more innovative in developing new ways of placing ads. For example, recent years have seen firms renting space encompassing the entire exterior of buses for advertisements.

One interesting finding is that there appears to be a density factor at play for advertising firm innovation. As in many other creative industries, when a geographic area gains more advertising firms, the creativity levels (and new advertising firms) increases in that area. This phenomenon may help explain how certain areas such as New York, London, and Berlin have become advertising centers for the world.

A firm's marketing department usually includes advertising but also helps the organization develop new product ideas and provides input from the wider environment to spur creativity. The marketing function may be seen as a cycle of creative work.

In the first stage marketing executives examine a firm's capability, market demand, and potential new ideas to identify possible products for development. Marketing then examines and develops the potential for these ideas for translation into actual products through marketing research including surveys and focus groups. Then the marketing department may work with research and development and the production department to develop a prototype, budget, and test marketing plan. Once the product is in production, the marketing department must find new ways of increasing public awareness including sales strategy, advertising, and a public relations plan. During this process marketing must also determine prices and distribution methods – tasks that often require creative thinking and a good deal of problem solving. Finally, after a market has been established, possibilities are created for new products and the cycle begins again.

Quality Management and Management Information Systems

Total quality management (TQM) may be seen as disciplined creativity. TQM began as a collection of methods to reduce defects; however, its scope has become much broader. While being defect free is a prerequisite for quality production, quality management's ultimate goal is to delight the customer – a much harder objective than simply eliminating defects. Reaching this objective requires creative thinking on the part of organizational workers.

Employees must be able to place themselves in the customer's position to determine what would please the user. Additionally, new production and delivery methods need to be created to fulfill these desires. Such tasks are made more difficult because these ideas are often restricted by manufacturing specifications that can be difficult to alter without changing an entire production system necessitating a systems perspective to these creative endeavors. Since quality management practices were developed in Japan it is largely a systematic, team-based, bottom-up approach. This approach allows organizations to capture the benefits of using creative problem solving and team based creativity. Procedures made famous in Japan include rotating jobs on a production line so workers are familiar with the entire product, allowing any worker to stop the line at any time and encouraging creative suggestions from everybody in the organization.

In addition to the need for creativity in TQM implementation, quality management can also spur greater organizational creativity. This relationship, however, appears to be somewhat complex, with only certain types of TQM being able to enhance organizational creativity. TQM that is more organic – more flexible and based on adapting quality principles to fit with an existing organization's structure and culture – are better suited for increasing innovation. The more mechanistic approach of simply applying existing quality management techniques does not seem to improve creativity even when overall productivity is enhanced.

Similar to total quality management, successful management information systems (MIS) development and implementation depends on creativity for success. The MIS function is to collect, store, and make available important information to organizational members so that they can better accomplish important tasks. Ideally, such information can be used to

guide an organization in setting future plans and goals. Deciding what information to process, however, requires creative thinking from those involved. When creating or improving an MIS, it can be unclear what information is important. MIS workers must, as with quality management workers, put themselves in the user's position and think holistically. Information needs must be identified, and future needs anticipated. In addition, creativity has to be employed to find methods to capture data and turn it into usable information.

Good MIS operations also provide support and enhancements for organizational creativity. A necessity for creativity is understanding prior creative endeavors, current conditions, and available resources. One challenge firms face is in reshaping their MIS capabilities to fully capture information that promotes creativity. Traditional MIS methods have been best suited to capturing relatively static, quantitatively based information. For the emerging innovation economy, methods are needed to capture more fluid, dynamic, and qualitative creative ideas. Some organizations have been using such MIS technology as wikis for this task.

Finance and Entrepreneurship

Organizational finance and accounting concerns itself with maximizing the flow of capital to support organizational operations. Innovations that are now commonplace include banks, checking, and stock markets. Banks and checking were introduced to the western world by the Knights Templar as a novel means for helping pilgrims travel to Jerusalem without having to personally carry large sums of cash. Similarly, the Dutch created the first continuously operating stock exchange in the seventeenth century as well as many financial transaction forms. More recently such financial instruments as 'penny stocks' and derivatives have been created. Creative derivatives based on mortgages encouraged high risk lending which contributed to the collapse in the housing and stock market in 2008, a reminder that creativity does have a potential dark side.

On the brighter side, recent financial innovations are being put to service for ethical improvements in developing nations. Several organizations have set up micro-loan services which provide low-interest small capitalization (usually less than \$100 and often as low as \$10) for individuals to start up small businesses. While these sums may seem low, they are usually sufficient to create a small business in developing nations – businesses such as weaving or cheese production. These entrepreneurs then repay the loans, and this repayment is used to fund new start ups. These small businesses then provide greater economic development and job growth to the (usually) impoverished areas in which they are located.

Entrepreneurship can be seen as the ultimate in creative business development. It requires an individual or small set of entrepreneurs to transform creative ideas into an entire business: finance, marketing, management, product development – all comprehensive aspects. So it comes as little surprise that so many new business methods and products arise from the entrepreneurial sector. Such firsts as the personal computer, assembly line, and the light bulb were realized through the action of entrepreneurs. Research consistently indicates that economic growth is largely driven by entrepreneurial activities, and some work indicates that it is the high-growth,

high-innovation firms that are primarily responsible for this increase. In addition, new entrepreneurial firms generate innovative spillover to a geographic region as when Hewlett-Packard's opening near San Francisco spurred the creation of the Silicon Valley.

Creativity in the Wider Business Context

Greater competition and uncertainty within a business environment increases the necessity for organizational creativity, and in turn new creative ideas increase environmental turbulence and competition. Firms scan the environment to adopt and adapt other organization's ideas, leading to new creative output in a syncretic process that can become self-reinforcing. In this way, organizations act as information brokers, where they combine existing ideas and products to create new innovations.

In addition to this environmental process, whole industries can be considered creative. Businesses in these industries have creative output as their main focus. Examples include the film, music, publishing, and video game industries. Such industries have brought great works of art to a wide public, and even led to the recognition of new art forms. For example, in France film and comic books have been officially designated as art forms – two modes of artistic expression developed in twentieth century. We may eventually see a new art form emerge with video games. This new industry already has produced revenues that surpass the long established film industry.

As mentioned earlier, the Internet has opened up many avenues for creativity in business, both for idea dissemination and for allowing new creative business start-ups. Major businesses made possible by the Internet include Google, Facebook, Amazon, and eBay. Less obvious is that the Internet has facilitated the appearance of several comic strips (or web comics) that support their creators through advertising and merchandising. Previously, only a limited number of comic strip artists could find financial success through the auspices of comic strip syndicates. Similar business models have been developed for independent musicians, and is emerging for video production.

Websites covering almost every subject imaginable are out there along with millions of blogs. The instant availability of information is changing newspapers and magazines as they make various creative attempts to find a way to reinvent themselves.

The Internet also provides support for creative activities and idea generation. It has allowed freer information flow throughout the world, leading to faster idea development and implementation. An example of these possibilities is the emergence of virtual bands. One person can decide to start a band and put out a call for members. A member can write the music and create a vocal track. This track can be sent electronically to other members who then record their own parts. Once all parts are recorded, the tracks can be merged into a single song and distributed electronically worldwide – without the band members ever meeting.

The Internet has also generated greater competition, requiring faster creative idea production from organizations. The combination of product purchase availability through the

Internet, and inexpensive shipping (even internationally) is eliminating the idea of local competition. Most any product – from a book to music to genetic testing – is as close as a computer: which in most developed nations means at everyone's fingertips. Venues such as eBay, Abe Books, and Amazon.com's cooperative agreements with outside sellers has created the possibility of a global small business with individual vendors marketing to international customers as easily as to neighborhood buyers. Industries that require physical presence for transactions (such as restaurants) have still been impacted by information availability on the Web. These conditions lead to greater competition and creativity as firms must act to retain customers when location is only a minor factor in purchasing decisions.

Another business-creativity area that the Internet has made possible is in open source software and the attendant distributed organizations that have emerged to create such software. While Richard Stallman is rightly regarded as the creator of free software, Linus Torvald was the first to truly take advantage of the developing Internet accessibility to distribute and gain outside support for his Linux operating system. His actions created a distributed organizational model where individual members had great control over the software's development. Indeed, this organizational model blurs the line between producer and consumer where users can provide direct feedback (and even actual product development) to shape the organization's output. So far it is unclear how this new organizational form will affect the wider business environment, but it is one of the more intriguing creative process aspects in the continually changing definition of what we mean by business.

Conclusions

Creativity and the business world must be viewed as partners – with each providing necessary functions to advance the other. Success in global business is increasingly driven by creative ideas, and information sharing's expanding global scope enhances all firms' creative action capabilities.

In addition to businesses' increased global scope, new technologies are lowering entry barriers for creative entrepreneurial action. Computers have been able to replace many dedicated hardware platforms for music, drawing, and film production, and this change is opening new opportunities for creative expression and sales.

Additionally, new communication media allows for creative individuals to set up worldwide performance venues, and develop these venues into profitable outlets. It is far easier for individuals to enter new business areas as technology becomes cheaper and more ubiquitous. One can easily imagine that the next Orson Wells or Eric Rohmer may shoot his or her films with inexpensive cameras, use collaborators from across the globe by transmitting the film electronically, edit the film on a computer, and distribute it through web based channels. Recently a director of an imaginative low budget robot video aired on YouTube was hired to direct a major film.

What is certain is that creativity and business will continue to enable the other to flourish and reach new levels. However, to reach the next level in this relationship, the developed world

must reach out to the developing world and bring it into this cycle. If entrepreneurial actions are a key process in this cycle then developing nations provide vast resources for future growth in both creativity and business operations. While developing nations have often been exploited for their natural resources, they have been neglected as opportunities for cooperative creativity and entrepreneurial development. Fully embracing such cultures can lead to syncretic development such as seen during the renaissance – a flourishing period of growth in creative output and business development largely driven by the intermixing of European, Mediterranean, and Middle-Eastern societies.

This process is already occurring in such nations as India. India has long been the leading film producer, and has exported its movies throughout Asia. Recent years have seen this export expand to top box office movies in Europe and North America. Similarly, partnerships with developed nations have led to increased high tech business expansion in India, and created a vibrant and growing export market for the country – a market that is returning creative business ideas to the world.

Combining a push for increased entrepreneurial activity in developing nations with increasingly ubiquitous communication infrastructures and cheap computing power promises to bring about an even more fruitful collaboration of business and creativity. As with the printing press, radio, telephone, and computer, each technological innovation that expands people's ability to communicate and share their creative ideas across increased distances will push the business/management—creativity cycle to higher levels. The free flow of creative ideas will continue to prove the strong and mutually reinforcing relationship between business and creativity.

Lewis Carroll (Charles Lutwidge Dodgson) 1832–1898

Writer

Author of *Alice in Wonderland and Through the Looking Glass*

D Morrison, University of California, San Francisco, CA, USA

© 2011 Elsevier Inc. All rights reserved.

This article is reproduced from the previous edition, volume 1, pp. 245–251, © 1999, Elsevier Inc.

CHARLES DODGSON was a mathematician and logician who taught at Oxford University, England, from 1851 to 1892. Under the name of Dodgson he wrote on mathematics and symbolic logic. He met Alice Liddell when she was 4 years old. On July 4, 1863, while on a rowing outing on the Isis river with Alice and her sisters he told the story of a little girl who went down a rabbit hole and had many adventures. Alice was 10 years old and Charles was 30. As a gift to Alice, Charles wrote and illustrated the story for her. In 1865, under the name Lewis Carroll, he published it as Alice's Adventures in Wonderland. Although Charles had been a frequent visitor to the home, three years after the boat outing Mrs. Liddell did not allow him to have social contact with her daughter again. The first book on Alice was a popular success and made Lewis Carroll famous. Six years later he wrote Through the Looking Glass and his fame as a fantasy writer for children was secure. Lewis Carroll's works are classics of nonsense, parody, and satire, and have contributed to popular awareness such characters as Humpty Dumpty and the Mad Hatter. Charles Dodgson is considered a pioneer in early photography. Although he took many pictures, including famous people such as Lord Tennyson, he is best known for his portraits of little girls. In the final part of his life Charles Dodgson turned his attention and talent to books on logic. His final book, Symbolic Logic I and II, completed around 1894–1898, is considered by some authorities as a significant contribution to the study of logic at that time. He was finishing the second part of this book when he died of pneumonia at the age of 66.

Lewis Carroll—Self portrait.

Early Years

Charles Dodgson came from a family with strong ecclesiastical traditions. His father was a clergyman. His great-great-grandfather and great-grandfather were both clergymen and the latter had been a Bishop. The family was pious and took life seriously. However, Charles, the eldest son, showed early

signs of irreverent humor. During his first 11 years the family lived in relative isolation. His playmates were his sisters. There were two sisters before Charles, and five girls and two boys afterward. Perhaps reflecting some family stress, seven of the children, including Charles, stammered. Charles began writing family magazines when he was 13 and published a short humorous story when he was 23. His early writings show the same parody and humor found in his adult works, and some, such as poems in the family magazine *Mismatch*, appear in his later writings such as *Jabberwocky*. Although he appears to have been happy at home at age 14 he entered public school at Rugby. This experience was a very unhappy one for Charles and contributed to his general aversion to young boys that continued throughout his lifetime. In contrast to other people's positive memories of him as a boy, Charles always viewed himself at that age in very negative terms. While at Rugby he maintained close ties to his brothers and sisters and wrote material for them that later appeared in *Alice in Wonderland* and *Through the Looking Glass*.

Oxford

Charles demonstrated considerable skill in mathematics and in 1851 he entered Christ Church, Oxford, as a student. He spent the rest of his life there. In keeping with the family tradition he entered Oxford with the plan to be ordained. However, his diary entries indicate considerable ambivalence regarding the matter. He was ordained a Deacon but finally in 1862 he made the official decision to not take the priestly orders. As faculty at Oxford he had difficulty as a teacher probably due in part to his stammer. His diary entries indicate his interest in theater and he published parodies in various magazines under the name of Lewis Carroll. During his early years at Oxford he also developed an interest in photography that he maintained for 25 years. At the time photography had been in existence for 17 years and Charles was 24 years old. He was a pioneer in this new field and he published articles and stories about the subject. Charles had public exhibitions of his photographs and he was invited to write a review of the 1860 London Photographic Society exhibition.

Photography and Alice

In 1855 Henry George Liddell became the Dean of Christ Church Oxford. He arrived with his wife, a son, Harry the eldest, and three daughters, Lorena, Alice, and Edith. Soon after the Liddells arrived, Charles met the children and was soon photographing them. He became a frequent visitor to the Liddell's home, apparently to see the children for there is little indication that he developed a friendship with either parent.

His contact with the girls was frequent but his relationship with Alice grew over the years. His photographs of her, such as Alice as a young beggar, indicate his complex feelings for her. It was on an outing with the three sisters that he first told the story of Alice's adventures underground. During that same year something happened because he fell out of the good graces of Mrs. Liddell. Three years later he seldom saw Alice again. Although he now had no contact with her he wrote *Through the Looking Glass*, which is the further adventures of Alice. For lack of documentation, the reasons for the disruption of his relationship with Alice are not well established. However, there is some evidence that Charles was interested in eventually marrying her. The two stories inspired by Alice are at one level descriptions of growing up in a dream world inhabited by characters who are animals and humans who are unpredictable. In her encounters Alice reflects common sense in an illogical and often frightening context. The jokes are always based on faulty syllogisms. Whatever the reason for his failure in his relationship with Alice, Charles Dodgson spent a great deal of his time after this entertaining little girls and photographing them. The photographs of the girls were often in various costumes that he provided, but frequently the photographs were of nude little girls. Most of the nude photographs have been destroyed, and there were many of them, but four have survived. That these were images of childhood innocence and purity is difficult to support, especially the reclining nude of Evelyn Maud Hatch.

His affection for little girls was captured in photography and Charles spent a great deal of his time in meeting them during vacations at the seashore, some friend's house, or on the train. He always obtained consent from the parents and took great delight in entertaining these prepubescent friends at his apartment or the theater. He had a bag of gifts and objects for magic tricks to gain an initial contact and he frequently gave a copy of his books on Alice as a gift. His many letters to little girls during this time are full of the nonsense found in his books, but frequently are vaguely concealed love letters full of sexual flirtations. He seldom entertained an adolescent girl or a mature woman. There is little to indicate that he had sexual contact with any female. He found young boys repulsive and never had a relationship with one. Photography allowed Charles to hold the idealized image of his girl friend's permanently and at one time he had a list of 107 little girls who were photographed or to be photographed. Suddenly in July of 1880, what had been a long standing passion in his life was given up. With little explanation in either his diaries or his letters at the time, Charles took no more pictures.

Portrait of Alice Pleasance Liddell.

Parallel Thought

One of the most interesting aspects of Charles Dodgson's personality is how he managed and generally succeeded publicly, if not internally, in keeping the imaginative side of his personality, which appealed to his little girl friends, separated from his more linear, logician side. Although the use of a pseudonym in published writings was not uncommon in the Victorian Period, in Charles's case it would seem that Dodgson and Carroll genuinely reflected aspects of one personality that functioned in two different affective styles: the evocative images in the Alice stories and the dry formulas of symbolic logic.

As a student at Rugby and Oxford, Charles demonstrated outstanding scholarship and talent in mathematics, classical humanities, and divinity. However, as a teacher in his chosen field of mathematics and logic it would appear that he was less than inspiring to his students and he gained little satisfaction from it. There are also indications that he found giving sermons a burden. The liveliness of his thought expressed in his fantasies for children was not expressed in his lectures and sermons. Perhaps his lifelong problem with stuttering accounts for some of this.

His early years at Oxford are noteworthy for his publications of nonsense and parody rather than logic. For example, after becoming secured in 1851 as a life member at Oxford, his major works beside the two Alice stories are *Phantasmagoria and Other Poems*, *The Hunting of the Snark*, and *Sylvie and Bruno*. The first two continue the exploration of fantasy found in the stories of Alice while *Sylvie and Bruno*, published at the time he was ending his career at Oxford, is a mix of fantasy and moral tale. Whereas the other children in *Sylvie and Bruno* are presented in ideal terms and generally not burdened with the more common childlike emotions, one boy, Uggug, is a hideous fat boy whose major function in the book is to be unpleasant. The book itself was a failure and is structurally unsuccessful in the attempt to combine a fairy tale with a moral message regarding the importance of Christian love. The story, combined with Charles's diaries and letters, is consistent in establishing the negative image that he had of young boys. Passages from the book indicate that when Uggug looks at Sylvie in a sexual way he becomes even more animal-like than usual.

At the time he was writing *Sylvie and Bruno*, Charles published several mathematical works under his own name. He had been teaching mathematics for 22 years. Three years later, in 1879, he published under his own name *Euclid and His Modern Rivals*. The years 1880–1881 appear to be important for Charles because he gave up his photography and lecturing. His letters and diaries from this time reflect a return to his long-lasting interest in word games and logic. For approximately the last 12 years of his life there is little original work on fantasy and Charles turned his attention to the problems of logic. He would not answer mail addressed to Lewis Carroll. There is considerable evidence that Charles found logic as a source of joy and order with the significant feature that it will "give cleanness to your thoughts and see your way through a puzzle," to quote from the preface to one of his works on logic. The result of his efforts at this time was *A Game of Logic*, which was written for the general reader, and his more ambitious project, *Symbolic Logic, Part I*. Charles thought that *A Game of Logic* was

written in such a style to appeal to children whereas *Symbolic Logic* addressed advanced logical concerns regarding paradoxes. *Symbolic Logic* went through four printings in his lifetime. He was writing *Symbolic Logic, Part II* when he died, and a manuscript of that book has been recently found. Although none of his contemporaries thought that his contributions to logic were exceptional, recent evaluations by such authorities as Bertrand Russell indicate that he was an original thinker who advanced logic beyond its Aristotelian limits to the methods of modern thought.

Conclusion

As a boy Charles Dodgson demonstrated a talent in mathematics and a joy in word games, puzzles, and nonsense. Up until age five his only playmates were four younger sisters. He saw himself as an undesirable boy and although he demonstrated more than a usual amount of affection for prepubescent girls, he disliked boys that age and avoided their company. Charles Dodgson–Lewis Carroll was characterized by a unique synthesis between fantasy and logical thought in a personality where concepts of self were rigidly separated and unavailable to conscious exploration. As Lewis Carroll, Charles attempted to establish affectionate relationships with very young girls in an effort to express the more affect-laden images of his thought. In his creation of images growing up in the Alice stories he combined fantasy and logic as they had

never been combined before. Interrelated with his affection for the real Alice Liddell and romantic images of that ideal was his lifelong passion for photography. Combining his interest in science and technology, as well as allowing him a socially acceptable avenue for his erotic wish to possess prepubescent girls, photography gave Charles Dodgson a great deal of aesthetic and erotic pleasure.

His creative efforts in his stories for children, really little girls, and his photographs of little girls are instructive examples of the contribution of conflict to creativity. These two passions, love of little girls and photography, dominated his early life. As he grew older he returned to the study of mathematics and symbolic logic. He pursued these with passion and took pleasure and comfort in the order and rules of that mode of thought. However, the unique creativity of his thought found expression in the irrational and illogical stories he wrote for an imagined little girl who was to never return his love.

Mary Cassatt (1844–1926), renowned for her depiction of women and children, was the only American member in the group of French artists known as the Impressionists. After exhibiting her work at the Paris Salon, Cassatt was invited to join the Impressionists by Edgar Degas. In addition to being a painter and a printmaker, Cassatt was also an advisor on art who influenced American collectors and subsequently impacted the holdings of major museums (Figure 1). She was also an early feminist and a strong supporter of women's rights, especially the right to vote. While Cassatt's fame in America increased after her death, she had greater success in France during her lifetime and at age 70 received their highest award, the Chevalier of the Legion of Honor.

Background and Family

Born Mary Stevenson Cassatt on 22 May 1844 in Allegheny City, which is now part of Pittsburgh, Pennsylvania, she came from a family of privilege and creativity. Ancestors on both sides of her family were landed gentry and Revolutionary war heroes. For generations they had been bankers, lawyers, and civil servants yet when her father Robert Cassatt started his own investment company, it was regarded as daring and risky. Business was Robert Cassatt's domain of creativity and he eventually became successful enough to retire in his forties and take his family to Europe for an extended stay. Her mother, Katherine Cassatt, was musical and their family home always included a piano. Lydia, her older sister, did needlework and weaving while her oldest brother Alexander Cassatt, like her father, turned his creativity to business. Alexander eventually became one of the richest men in America and as head of the Pennsylvania Railroad, was the person who linked their trains by tunnel to New York City. Her younger brother Gardner also became an investment banker and the head of his own firm. By manifesting a variety of creative modalities, the Cassatt family showed great evidence of everyday creativity, which encompasses the many ways it is possible to be creative in daily life.

Robert and Katherine Cassatt lost a son and a daughter in infancy but of their remaining five children, Lydia born in 1837, Alexander born in 1839, Robert, born in 1840, Mary born in 1844, and Gardner born in 1849, Mary Cassatt was closest to her brother Robert, known as Robbie. When Robbie was seven, he began showing symptoms of tuberculosis of the knee. His worsening pain and the prospect of good medical

care in Europe was one of the reasons the family traveled there. Another reason was the availability of excellent education for their children, specifically engineering schools for Alexander, the oldest son. When the Cassatt family sailed for Europe in June of 1851, their first stop was England where they saw the Great Exhibition in London's Crystal Palace. In August the family sailed for Paris where they stayed two years before moving to Germany for another two years.

Having taken classes in French and German, Mary Cassatt was fluent in both languages by age 11. Years later this fluency in French would be an immeasurable aide to her career in France. Another benefit was that having spent years in Europe as a child, she did not experience it as a foreign place when she returned to live there as an adult. The Cassatt family was going to stay a third year in Germany, but when Robbie succumbed to illness at age 13 they returned to America. After being sick for years, he died just days after Mary Cassatt's eleventh birthday. It was a tragedy for the entire family but it may have affected Mary the most because Robbie was her steadfast companion throughout childhood.

Turning to Creativity

In response to Robbie's death, Cassatt may have turned to creative activity to soothe and distract herself from this great loss. The psychologist Ernst Kris (cited in Niederland, 1967) notes that children tend to be creative during times of stress and when Robbie died at age 13 the resulting trauma may have turned Mary Cassatt to a life of art. Eminent artists usually show signs of creativity in childhood and while Robbie's death was not the only reason for her choice of career, it was an important stimulus in her early life. Each one of our actions is generated by multiple causes which are often events in our lives, themselves the result of an almost infinite number of stimuli. Yet certain of these events have more profound an impact on us than others becoming the occurrences that shape our destiny. One of these occurrences for Mary Cassatt happened shortly after Robbie's death and may have intensified her desire for creativity. It was seeing great art at the *Exposition Universelle*, the Paris World's Fair.

On their way back from Germany to America, the Cassatt family stopped in Paris to see the *Exposition Universelle* with its display of art by Ingres and Delacroix as well as the work of Courbet in a separate pavilion. Exposure to these works of art

Figure 1 Mary Cassatt, Self Portrait. ca. 1880. Watercolor on paper.

may have made a great impression on the young Cassatt, especially seeing the paintings by Courbet, who became one of her favorite artists. Bullard says that this experience could have inspired her desire to become an artist. Art lessons had been part of Cassatt's education and learning to draw provides a greater appreciation when viewing the art of others.

Seeing great works of art can be life changing for a child recently immersed in tragedy. Their beauty may well have been a distraction from Cassatt's pain and experienced as healing for the 11-year-old girl. Later on Cassatt would repeatedly turn to art as healing in response to the difficulties in life. It is possible that Robbie, like other children with debilitating illnesses, made art while he was sick because he was unable to be physically active. Creativity could have been his method of occupying himself during years of confinement. If this is so, then Mary Cassatt and Robbie may have shared an interest in creativity and pursuing art may have been experienced as a way to keep him close to her after he died. When children cannot comprehend the irreparable nature of death, they may want to restore the lost object with a greater intensity than that found in adults. Losing a sibling in childhood may inspire strivings and fantasies of restitution making creativity in response to the object loss a restorative experience. Creative activity can also provide a sense of companionship for a child suffering from loss and feeling alone. As such it becomes a way to search for wholeness after trauma. Of course losing a sibling is hardly a sufficient condition for becoming a creative artist. Innate talent is also crucial, as well as having encouragement from a parent or other caretaker.

When the Cassatt family returned to America they lived in West Chester, Pennsylvania for three years before moving to Philadelphia. By age 15, Mary had grown into a tall athletic girl with strong interests in literature and politics but said her real passion was for drawing and painting. Her interest in art was so intense that she was the first person to sign up for a class at the Pennsylvania Academy of Fine Arts. At that time the Pennsylvania Academy of Fine Arts was the leading art school

in the country and dedicated to producing professional artists. During the years of Cassatt's attendance there were a number of students who went on to established careers. Among the women were Anne Whitney, Emily Sartain, and Fidelia Bridges and male students who achieved eminence were Thomas Eakins, Robert Wylie, Earl Shinn, Harry Moore, and Howard Roberts.

When Cassatt finished her classes at the Academy, the family moved into their new estate in Westtown, Pennsylvania. Cassatt still traveled to Philadelphia for art exhibitions and to learn on her own by studying examples of great art in the museums, which she preferred to organized classes. At home in Westtown Cassatt used the local inhabitants as models for her art, a practice she would continue throughout her career no matter where she lived. Although Cassatt enjoyed horseback riding through the countryside, she eventually realized that Paris was the place she wanted to be. When she told her father about her plans to become an artist and study in Paris, he retorted, "I would almost rather see you dead" (cited in Hale, 1987: 31). Robert Cassatt, who wanted to keep his daughters close to home, succeeded with his older daughter Lydia, who was unmarried at 28 and still living with her parents. Mary Cassatt, who later said, "Oh I am independent! I can live alone and I love to work" (cited in Munson, 1999: 55). Sailed for France at age 21.

An Artist in Europe

Cassatt's mother accompanied her to Paris in late 1865 and stayed there for about half a year seeing that her daughter was settled in as a boarder with a trusted family. Within that time friends from the Pennsylvania Academy, such as Thomas Eakins, Howard Roberts, and Eliza Haldeman also arrived in Paris. In France Cassatt studied with the painters Charles Chaplin, Jean-Léon Gérôme, and Thomas Couture. She also spent a large part of her time copying works in the Louvre and took sketching trips to the country. By 1868 she had her first painting accepted into the Paris Salon, which showed a young woman playing the mandolin. When the Franco-Prussian War was declared in 1870, Cassatt went back to Philadelphia but soon realized that her true focus was in Europe and returned there in 1871, this time to Parma, Italy.

There she studied the paintings of Correggio and Parmagianino and learned print-making techniques from Carlos Raimondi. After Italy she traveled to Spain, first coming to Madrid and then staying in Seville. In Spain she completed her first major body of work, again using local inhabitants as her models for the young women and toreadors in the paintings. Two of the canvases, *Spanish Dancer with a Lace Mantilla*, 1873 and *Torero and Young Girl*, 1873 were later shown at the Paris Salon. Previously Cassatt exhibited her work under the name of Mary Stevenson and then Mary Stevenson-Cassatt but after 1873, she used Mary Cassatt and continued with that name for the rest of her life.

An Advisor on Art and a Feminist

Returning to France in 1873 Cassatt met Louise Waldron Elder, an American woman studying at a boarding school in Paris. Elder, who was very interested in art, admired Cassatt's

knowledge and abilities and the two became close friends. When Cassatt convinced Waldron to buy a Degas, it became the first Impressionist work that was brought into America. Later when Elder married E. O. Havemeyer, Cassatt was very influential in guiding their art acquisitions which became the Havemeyer Collection and eventually part of New York's Metropolitan Museum of Art. Trusted by all the important Impressionist and Realist painters and collectors, Cassatt was a connoisseur of French art, who also advised them on purchasing works by old masters such as Goya and El Greco. Cassatt and the Havemeyers formed an art collecting alliance that became one of the greatest in the history of American culture.

In addition to art, both Mary Cassatt and Louisine Havemeyer shared a passion for women's rights, especially the right to vote. In 1912 they made plans for an art benefit in New York featuring the works of Degas and Cassatt to aid the suffrage movement. Although Cassatt and Havemeyer admired Degas' work, it he was an unusual choice to aid a feminist benefit. Degas was extremely conservative and known for his misogynistic remarks, such as the time he saw Cassatt's painting, *Two Women Picking Fruit* and exclaimed, "No woman has a right to draw like that."

Joining the Impressionists

Despite his prejudices toward women Edgar Degas admired the work of Mary Cassatt. In 1877, when he invited her to show with the Independents, better known as the Impressionists, Cassatt said, "I accepted with joy." Degas also bought her paintings and eventually owned 90 of her prints. Cassatt's palette had been getting lighter since 1873. The deep shadows of her earlier images were gone and she had begun posing some of her models outdoors, as seen in the 1875 paintings *Picking Flowers in a Field* and *Head of a Young Girl with Blue Eyes Outdoors*. Although her work fits in with the Impressionist style, it was a leap of courage for Cassatt to forgo the traditional route of showing at the Paris Salon and joining what many derided as a group of outcasts. Impressionist artists such as Edouard Manet, Auguste Renoir, Claude Monet, Camille Pissarro, and Berthe Morisot are now well known but then they were considered to be rejects of the Paris Salon.

Looking back at Cassatt's bravery in joining the Impressionists, the art critic Gustav Geffroy said in 1893 that "Miss Mary Cassatt, though, has not gone the way of fashion, of the popular styles, of success, for she has gone to the disparaged Impressionists." He continued in his admiration, stating, "A similarity of vision determined this choice, and this vision has expanded, has become increasingly searching, this strong-willed woman has truly learned to paint." Other American women painting in Paris at the time such as Elizabeth Gardner and Mary MacMonnies remained within the academic establishment and continued showing at the Paris Salon. While both of them had success during their lifetimes, their posthumous reputations have greatly diminished. In contrast, Cassatt rejected academic art and the Salon saying, "I had already recognized who were my true masters. I admired Manet, Courbet, and Degas. I hated conventional art. I began to live."

Joining the Impressionist movement was a life changing event for Cassatt. It brought her into a group of painters that

were altering the course of European art. In addition she was now able to enter into French culture and society at a level that had previously been unavailable to her. Cassatt not only exhibited with the Impressionists but became an active member of the association, using her considerable business and organizational skills to promote their work and help arrange the exhibitions. She was first invited to participate in the fourth Impressionist exhibition and continued to show her work in the fifth and sixth Impressionist exhibitions. Following Degas' lead, she refused to participate in the Seventh Impressionist exhibition when conflicts broke out among its members, but showed her work again in 1886 as part of the eighth and final Impressionist exhibition.

Family Responsibilities

In 1877, the same year Cassatt joined the Impressionists, her mother, father, and sister Lydia came to live with her in Paris. Her father who had gone back to work after his earlier initial retirement now retired again and he, along with her mother and older sister Lydia were moving to France as their permanent home. Fully accepting the responsibilities for her family, Cassatt gave up her previous apartment-with-studio in the artist's quarter and found a larger apartment on the Rue Beaujon in an elegant neighborhood near the Champs-Élysées that could accommodate the entire family. She also rented a studio for painting in her former neighborhood.

Neither of her brothers moved to Paris, but remained in Pennsylvania where they had successful careers and raised their families. In 1868 her older brother Alexander married Lois Buchanan, a niece of President Buchanan and had four children, while her younger brother Gardner married Eugenia Carter in 1883 and took his bride to Paris to meet the family. They had three children. Cassatt enjoyed painting her nieces, nephews, and other family members, but the portraits of her sister Lydia from 1877 to 1882 are among her best works of art. They include *Lydia Reading the Morning Paper*, 1878, *Five O'clock Tea*, 1880, *Lydia Crocheting in the Garden at Marly*, 1880 (Figure 2), and *Lydia Working at a Tapestry Frame*, 1881.

Figure 2 Mary Cassatt, *Lydia Crocheting in the Garden at Marly*. 1880. Oil on canvas.

After suffering from poor health her entire life, Lydia died in November 1882 at age 45 from Bright's disease, a failure of the kidneys. Cassatt nursed Lydia when she was sick and her sister's death was an emotional blow. As an unmarried woman, she had assumed she would live with her unmarried sister Lydia and they would grow old together but now that could not happen.

In 1884 Cassatt and her parents moved into an apartment at 14 Rue Pierre Charron that had room for Cassatt's studio. Three years later, they moved again, this time to an apartment and studio on rue Marignan near the Champs-Élysées that had an elevator and central heating, amenities that were a great help to her aging parents. Cassatt maintained this residence for the rest of her life. In 1891, her father died at age 85 and Cassatt nursed him in his failing health, as she had done with her sister Lydia and would do in her mother's final illness and death in 1895. Cassatt's admiration for her mother was evident in the portraits she painted of her, such as *Reading Le Figaro*, 1877–1878, which shows an intelligent strong looking woman reading the newspaper. The health problems in her elderly parents brought out a very nurturing aspect in Cassatt. This capacity for caring affected the imagery of Cassatt's work, resulting in a greater closeness between mother and child as in the pastel *Hélène de Septeuil* 1889–1890, where a woman holds a child so closely that their faces touch and seem to meld into one.

Beyond Impressionism

Although Cassatt continued to keep the sunny palette of Impressionism throughout her life, her paintings began to take on more structure and definition in the mid-1880s with works such as *The Family*, 1886 and *Girl arranging Her Hair*, 1886. With an increasing emphasis on line that highlights her excellent skills in drawing, the paintings become stronger, culminating in *The Bath*, 1892, and *The Boating Party*, 1893–1894. A strength in Cassatt's work is strong drawing and excellent composition with a lack of sentimentality. In April 1890 Cassatt repeatedly went to an exhibition of Japanese prints at the École des Beaux Arts with Degas and friends. Japanese woodcut prints, known as ukiyo-e, were available in Paris before but this exhibition with its hundreds of works made an enormous impact on Cassatt. That summer and fall Cassatt worked on an etching press with a professional printer. She used 250 color plates, each one of which she inked by hand, to create a series of 10 color prints, showing Japanese inspired images of Western daily life. These are her greatest graphic works and among the most esteemed prints created in the nineteenth century.

In 1891 Cassatt had her first one person show at the Durand-Ruel Gallery in Paris; it would be followed by others including a show in their New York gallery in 1895. Beginning in 1907 she also exhibited at the Vollard Gallery in Paris. In 1892, Cassatt bought what was to be her permanent country home, the Chateau de Beaufresne in Mesnil-Theribus, 50 miles northwest of Paris. In that year she also began work on a painting called *Modern Woman*, a large 12 by 58 foot canvas that was commissioned to be a mural for the Women's Building at the 1893 Chicago World Fair. Cassatt's three part

painting showed women picking the fruits of knowledge and education, pursuing fame, and remaining attentive to domestic responsibilities. The mural elicited great praise in close viewing before it was hung but unfortunately, the artist had not judged how it would appear at a distance. In place near the ceiling, it looked garish and unclear, eliciting a very negative public response. Cassatt treated negative reaction to the mural just as she had treated negative responses to her art in the past – she ignored it and kept on working.

Degas, a Mentor in Art

Of all the artists Cassatt knew in her lifetime, Edgar Degas was the one who was most important to her and the artist with whom she had the deepest and most complex relationship. He was also the person who exerted the greatest influence on her creative process. Even before they met in 1877, they admired each other's work. The first time Cassatt saw one of Degas' pastels in an art gallery window she said, "I used to go and flatten my nose against that window and absorb all I could of his art. It changed my life." When a friend showed Degas a work by Cassatt, he said, "There is someone who feels as I do." Degas was ten years older than Cassatt and although she was American and he was French they had a great deal in common. Both came from backgrounds of wealth and privilege. Degas' father was a banker and because his mother was an American from Louisiana, he may have felt a special rapport with Cassatt. This rapport may have been intensified by the longing Degas felt for his mother, who died when he was 13. Degas had visited his American relatives and one of his early oil paintings, *The Cotton Exchange in New Orleans*, 1873, shows a scene from his trip to Louisiana.

From 1879 to 1880, Cassatt and Degas worked together making prints for *Le Jour et La Nuit*, a journal that Degas had planned. Although the journal was never published, it strengthened their friendship and encouraged Cassatt to focus on printmaking as well as painting. While Degas was helpful, he had a very difficult personality that could be abrupt and irritating. Cassatt's father, whom she adored, also had a stubborn and difficult personality, which was possibly one of the reasons that she could tolerate Degas. Yet, unlike her father, who had discouraged her from pursuing a career, Degas strongly supported her work and became her mentor. He would stop by her studio to see her progress and in one painting, *Little Girl in a Blue Armchair*, 1878, he even found the model and painted on the background. Degas encouraged Cassatt to focus on drawing which became one of the greatest strengths in her work. Cassatt was also helpful to Degas. She tirelessly promoted his work by using her influence to ensure that it was consistently bought by American collectors visiting Paris.

Degas and the Creative Imagination

The psychoanalyst Kathryn Zerbe, noting the artist's strong feelings for her father, says that in Degas, Cassatt found an idealized paternal transference, which enhanced her creativity. Zerbe believes that Degas' influence transformed Cassatt's work and suggests that sometimes a woman's creativity can

be inspired through attaining a special position with an important male figure in her life. This man, who is usually her father, admires her 'masculine' aspects such as creativity, ambition, and motivation for success. He also encourages the woman to identify with his interests and achievements. This happened twice with Cassatt; first in assimilating her father's fervor for business and success, and then with Degas, who became a role model and inspiration for her art. It was he who suggested that Cassatt paint mothers and children, a subject matter that remained central throughout her career.

Both Cassatt and Degas remained unmarried for their entire lives and despite her love and admiration for him it is unlikely that their relationship was sexual. We cannot know this for certain because Cassatt destroyed all her letters from Degas before she died and most of her letters to him were lost. Instead, their connection was most likely one of inspiration and desire channeled into art. Taking a Freudian point of view, Zerbe believes that Cassatt's paintings represent an unconscious desire to have Degas' child as well as being her own symbolic offspring. Even if they have biological children, it is very common for artists to consider the products of their creativity as children. Throughout the ages, artists such as Michelangelo have regarded their creative works as their children and Freud noted this phenomenon. This parental view of creativity is not exclusive to visual artists. The writer Charles Dickens said his favorite child was David Copperfield, the hero of his novel by the same name.

In spite of their mutual passion for art, Cassatt and Degas did not always agree. During the Dreyfuss Affair, Degas was certain that Captain Alfred Dreyfuss was guilty of treason, while Cassatt believed in his innocence. History has proven her correct. Dreyfuss, who was wrongly accused and imprisoned because of anti-Semitism, was later exonerated and honored by France. Cassatt could also be difficult. A very outspoken and critical person, she had a long history of broken friendships throughout her life. It was inevitable that two such strong-willed people would have rifts but when these occurred, mutual friends would bring them together again. At the very end of his life when Degas was blind, going deaf, and losing his cognitive faculties, Cassatt persuaded his niece to take care of him during his final two years. Expressing her sorrow when Degas died in 1917, Cassatt said, "He was my oldest friend here and the last great artist of the nineteenth century. I see no one to replace him."

Public Response and Growing Fame

In the autumn of 1898 Cassatt made her first trip back to America since 1871. She was so little known at that time, that even in her home town of Philadelphia, the *Philadelphia Ledger* wrote, "Mary Cassatt, sister of Mr. Cassatt, President of the Philadelphia Railroad returned from Europe yesterday. She has been studying painting in France and has the smallest Pekinese dog in the world." Posterity has reversed the order of fame in this nineteenth-century newspaper citation. Alexander Cassatt, an extremely prominent business man of his day, is now better known as Mary Cassatt's brother. Also, Cassatt had finished her studies decades before this trip and her little dog was a Brussels Griffon. True to her strong work habits, Cassatt

Figure 3 Mary Cassatt, *Mother and Child (The Oval Mirror)*. ca. 1899. Oil on canvas.

did a series of portraits in America, which include her pastels *Frances L. Hammond as a Child*, 1898, *Portrait of a Grand Lady (Mrs John Howard Whittemore)*, 1898, and *Boy with Golden Curls* 1898 (see [Figure 3](#)).

Ocean voyages were extremely difficult for Cassatt who suffered from severe sea sickness yet she visited America twice more in her life, in 1904 and then again in 1908–1909. On these later trips, her fame in America had grown. In 1904 she was the guest of honor at the Art Institute of Chicago's opening for its annual exhibition and she was also awarded the Lippincott prize and the Harris prize, both of which she rejected. Cassatt did not approve of prizes given to older established artists. Instead she believed they should go to struggling young art students and instructed that the 500 dollar Harris prize be given to Alan Philbrick, a young American artist working in Paris. While Cassatt's outspoken opinions against the art establishment and her concern for struggling art students made her a heroic figure to young American artists working in France, those that met her in person were intimidated by her arrogant and austere demeanor. There was a prize she did accept. In 1904 France gave her its highest award, the Chevalier of the Legion of Honor.

A Painter of Women and Children

Mary Cassatt's work is almost exclusively about women and children. Grown men are rarely depicted in her painted world. Degas encouraged Cassatt in this subject matter because he believed that "only a woman can paint infancy. There is a special feeling that a man cannot achieve." The first book written about Cassatt was called *Mary Cassatt: A Painter of Mothers and Children* by the writer and art critic Achille Segard. Cassatt had previously been included in anthologies of Impressionist painters but this was the first book dedicated solely to her work and other books would follow. Yet the subject matter

of women and children for which she is best known and admired, eventually became a limitation later in her career.

Although Cassatt was a highly intelligent woman, who read widely, none of her literary knowledge is conveyed in her art. After her mother died, Cassatt turned to spiritualism in an effort to contact her but without results, yet none of this metaphysical interest is apparent in her work either. Instead, the imagery remains largely of interior scenes depicting tender moments between women and children. While Cassatt created extremely strong works like *The Bath*, 1891, showing a mother bathing her child, in her late works the mother and child theme is repeated with too much similarity. In addition the figures are sometimes less well drawn as in *Woman and Child Admiring a Baby*, 1906 and *Children Playing with a Cat*, 1908. One of the reasons that Cassatt stayed with the same subject matter to the extent of producing less creative paintings was the pressure to keep making art that sold well.

Acknowledging the decline in her later pieces Cassatt blamed her art dealers saying, "I sold my soul to the dealers, that's all. It was the dealers who stole my life!" Dealers can exert great pressure on artists to keep creating commercially viable works. Cassatt's art with its subject matter of mothers and children had widespread appeal that sold easily. Too often, galleries see art as a commodity and view sameness of product as a factor that can encourage continued sales. Yet the pressure to sell also came from Cassatt. She was an excellent business woman, who described herself as "ravenous for money." Raised in an atmosphere of currency and investments, Cassatt used that business intelligence to guide her successful career. Selling art was of paramount importance to her.

Her Later Years

Another reason for the sameness in Cassatt's work may have been her personal resistance to change. As she aged, Cassatt, who was always opinionated, became rigidly self-righteous and was unable to transform her work even when faced with an opportunity to guide it in a new direction. The opportunity was her encounter with Egyptian art in 1911 when she journeyed to Egypt with her brother Gardner and his family. Cassatt admitted she found Egyptian art overpowering, saying, "I am crushed by the strength of this art. I wonder though, if I can ever paint again."

After the trip, Cassatt had a breakdown that manifested in emotional and physical exhaustion. Other creative people such as Charles Darwin, Elizabeth Barrett Browning, and Florence Nightingale turned their illness into a time of productivity and there is a long history of visual artists who also used illness to transform their lives and their work but Cassatt did not in spite of suffering from both incapacitating physical exhaustion and severe emotional stress. Although she mused in Egypt "fancy going back to babies and women to paint," when she regained her health that is what she did until her eyesight began to fail. Diagnosed with cataracts in 1912, Cassatt underwent a series of operations beginning in 1917 but none of the operations were successful and they ultimately hastened her loss of sight. Cassatt had also developed diabetes, which she attempted to control through a restricted diet.

In the later part of her life Cassatt had the extended companionship of her very loyal and long term housekeeper,

Mathilde Vallet. It was Vallet who took care of the artist in her older years and final illness. In gratitude Cassatt left Vallet a number of artworks to provide her with financial security. One of the pieces that Cassatt bequeathed was a portrait of Vallet tenderly holding the artist's nephew called *Woman and Child (Mathilde and Robert)*, 1885. In her sixties, Cassatt became friendly with James Stillman, an American banker living in France. He bought 24 of her works, and like the Havemeyers, valued her advice on collecting. It is generally thought that Stillman asked her to marry him and that she declined. Yet Cassatt and Stillman continued to be close friends and he eventually returned to New York in 1916.

Although blind for the last years of her life and unable to paint, Cassatt remained dedicated to art and conveyed her enthusiasm to the young artists who continued to visit her. Diabetic for many years, Cassatt died in 1926. As a Chevalier of the Legion of Honor, she was given a ceremonial funeral and was then buried in the family plot in Mesnil-Théribus near her summer home the Chateau de Beaufresne. During her lifetime Cassatt, who was called both "one of the glories of France" and "The Most Eminent of Living American Women Painters," still wondered whether posterity would recognize her. After death her fame has continued to increase, granting Mary Cassatt a strong, secure, and admired place in the history of art.

Paul Cézanne 1839–1906

Painter

P Machotka, University of California, Santa Cruz, CA, USA

CÉZANNE is a painter of timeless accomplishment, radical innovation, and inestimable importance for the art of the 20th century. Paradoxically, the work by which he influenced those who followed was very different from the painting he had intended to do as a young man. His initial aims were to represent events, mostly imaginary and highly emotional; his achievements, however, were paintings that were based on close observation of visual reality, complex yet resolved, and revealing a simultaneous interest in the structure of things and the richness of perception. This change seemed more a matter of internal development than of external constraints, and was due to a change in the importance of perception, rather than imagination, as the starting point of his work.

Paul Cézanne: Self-portrait before a pink background, c. 1875. Used with permission from Erich Lessing/Art Resource, NY.

Childhood and Adolescence

To understand how Cézanne created, ideally we should emphasize in equal measure the era in which his early ideas were formed, the teachers and contemporaries who influenced him, and the early experiences which determined his character. We should also look at the makeup of his adult personality, the material support available to him, the conditions under which he worked, and the specific talents that gave his work its form and quality. Alas, no account of a painter is that complete, and no interpretation of creativity that firm; in Cézanne's case, although there is much information on his adult life and the context in which he developed and worked, the record of his childhood is incomplete. And talent, of course, is always difficult to analyze.

Nevertheless, we do know something about his childhood and considerably more about his adolescence. Born in 1839 in Aix-en-Provence, France, as the first of three children of

Louis-Auguste Cézanne—a self-made man who rose from hatter to banker by dint of honest, hard work—and Anne-Elizabeth Aubert, who later became Louis-Auguste's wife, he held his father's character and practical attainments in awe but resembled his mother in temperament: lively, and possibly nervous and depressive. He received an excellent education in the public schools of Aix, and at the age of 13 formed a close friendship with an equally sensitive and intelligent young man who later became the novelist Emile Zola. We must note right away that his temperament was not suited for what was expected of him, that is, to follow in his father's footsteps—even with the refinement of law training—and we would be right to suspect that his attitude toward his father was a mixture of admiration and rebellion. Both aspects of the attitude ultimately bear on his work. During his adolescence, however, the friendship with Zola (and a third companion, Baille) was formative, and crucial emotionally and aesthetically. Rewald, on whom all the biographical information here is based, writes,

The three friends found themselves closely drawn together by a number of unusual interests and ambitions, and at school they came to be known as the "inseparables." They took long walks together over the countryside around Aix, and passed the time fishing, swimming, and reading verses by Homer and Virgil... Artistic questions particularly absorbed them and they discussed everything that was on their minds, persuading each other that they had a great and extraordinary destiny. Zola wrote poetry which he read to his friends, and they in turn wrote verses. Zola found Cézanne's more poetical than his and encouraged him to continue his efforts.

The friends in fact also wrote three-act comedies in rhyme, and pretended to hunt; but according to Zola's later notes, "The hunt always ended in the shade of a tree, the three of us lying on our backs with our noses in the air, talking freely of our loves. And our loves, at that time, were above all, the poets." Even such a brief reconstruction of the adolescent years says much about the conditions of Cézanne's future work. There is the love of the beautiful countryside, the capacity for intense friendship, the apartness from the crowd—and the intellectualized handling of adolescent concerns—the capacity for intense artistic work, and of course the dawning decision to dedicate oneself to art. What Zola and Cézanne understood by art, and by its purpose, was not yet divided into the visual and verbal. Art served to express the emotional concerns already evident to them: love, romance, disappointment, remorse, guilt, and even death.

They resolved that if they succeeded in becoming artists, these would be their subjects. Real love would be postponed for now; it would be achieved only through becoming an artist. One is reminded of Freud's comment on the role of wishes

in creating art: the artist creates because his unfulfilled wishes drive him, and later, when he has succeeded in expressing them in an artistic way, reality may grant them. As a description of Cézanne's and Zola's initial motives—of their direct sublimation of personal concerns into artistic ones—this is quite apt; but we shall see that motives change as artists grow, and that Cézanne grew into a different artist than he had foreseen.

Attempting to Make a Decision

When Cézanne was 19, Zola left for Paris to become an artist, and the two friends expected to join him after taking their exams. Cézanne in fact took three years to get away (Baillie never did), and the hesitations of those three years, and the correspondence he kept up with Zola, help us reconstruct his psychodynamics. Zola tried to bolster Cézanne's self-confidence and kept encouraging him to come to Paris. Cézanne instead studied for his baccalaureate exams, and to satisfy his father entered law school. This failed to interest him; increasingly he dreamed of painting, and enrolled in the free drawing academy of Aix, where he at least studied from plaster casts and the living model. He also became acquainted with the work—some of it landscape work—of Provence's painters. Eventually his father came to understand that painting was what Cézanne most wanted to do, gave him a monthly stipend, and went with him to Paris to help set him up.

It should be noted that Cézanne, fearing his father's reaction, never confronted him openly, and that without the latter's unstated understanding and ultimately lifelong material support, would never have become a painter. In the intervening correspondence Cézanne often gave vent to his robust poetic talent and inadvertently preserved for us a record of his inner conflicts. Writing spontaneously, in addition to the chatty news, he might begin or end with a poem. In one poem, Hannibal feels guilty before his father for having stayed up and caroused instead of defending his country; in another, a young man lost in the woods is about to be rescued by a beautiful woman who bares her breast to him, only to turn into a skeleton as he attempts to kiss her. Pleasure seemed always alloyed with pain, guilt, or even death. Cézanne began his artistic career, then, with more than the usual anxiety about love and a more than usual fear of his father; he also went to Paris with some training in art and acquaintance with Provençal painters, and the conception of art as predominantly narrative.

He was also easily discouraged; he returned home after five months and resigned himself to working in his father's bank. This, too, made him utterly unhappy, and a year later he was back in Paris. He returned to the studio where, without instruction, he could work from the model. There he met some of the young painters who, 12 years later, would exhibit together and receive the nickname "Impressionists." Monet and Renoir, nearly the same age, would eventually become his friends, and Pissarro, 10 years older, would become friend, supporter, and admirer—not a trivial feat in the early years—and later embody and communicate a devotion to landscape painting when they came to paint side by side.

Early Development as a Painter

For the first 10 years or so of his painterly career Cézanne's subject were mostly narrative but his style varied considerably. The narrative pictures were quite unlike his mature work: religious scenes alternating with sexual ones, to be replaced with an orgiastic banquet, a lugubrious picnic scene, an autopsy, or a murder. The mood might be straightforwardly narrative or ironic; within the composition there might be a bald man looking on, resembling the Cézanne of the time (see *Pastorale*, Figure 1). Many paintings, though not all, are dark in tonality, and equally many depend on an interplay of slashing diagonals for their organization.

In some respects his subjects appeared to continue the concerns he had shared with Zola when they were 16, but they also served to illustrate stories, fables, and myths; the two purposes were closely joined. What is remarkable about the early paintings are two qualities. One is their uncommon verve—their utter frankness and originality. No painter of his time painted anything so risky and occasionally so blatant, or so free of the constraints of previous painting authority. The other is the evidence they give—when one sees the originals, rather than reproductions—of a search for a self-consistent style. Over 10 years the style changed radically, sometimes abruptly, but within each painting it remained consistent. Even in the face of the apparently turbulent subjects, which seemed closely connected with the tenor of the fantasies Cézanne had written out in his poetry, he seems to have been able to exert some degree of painterly control.

Nevertheless—and we reach the crux of the psychodynamic question regarding the evolution of his style and his ultimate discovery of a mode of working that was as satisfactory as it was successful—his most successful paintings were done from observation. Portraits (*Louis-Auguste Cézanne, père de l'artiste, lisant L'événement* of 1866, *Achille Empereire* of 1867–1868) and still lives (*La pendule noire* of 1867–1869) can be counted as the masterpieces of this first decade, and several landscapes are calm and well realized. What they have in common is a

Figure 1 Cézanne, *Pastorale*, ca. 1870. Musée d'Orsay, Paris. Used with permission from Erich Lessing/Art Resource, N.Y.

mode of working—they are no longer based in imagination—and a fully realized form: a well-balanced composition free from excessive tensions.

Pissarro and the Observation of Nature

Clearly Cézanne's best painting would depend on harnessing his powerful temperament by observation. We do not know to what degree he was aware of this; we can say at least that in his old age he was quoted by a young friend (Gasquet) as saying that his only method afterward was "hatred of the imaginary." We can assume that he would have been confirmed in this development by painting in Pissarro's vicinity, between 1872 and 1874, sometimes side by side in the open air. Pissarro taught and exemplified a patient observation of nature, and Cézanne even began to record the effects of light—in the manner of the colleagues who would hold their first exhibit in 1874 and receive their nickname from Monet's painting, *Impression, Sunrise*. We may conclude that not only would Cézanne be supported by Pissarro in valuing observation over fantasy, but that he would see the expressive possibilities of landscape.

In the years to follow he would give up the effects of light but continue to observe attentively. A certain conservatism (which could be observed much later in his political views), shown in his admiration for the art of the museums, made him turn away from his colleagues' flocculent innovations and return to portraying the solidity of things. Paradoxically, this conservative bent created his most radical innovations. It must also be added that Cézanne never gave up painting from imagination altogether; although by the mid-1870s he no longer painted scenes of sexuality and violence, he did replace them with bather compositions, male or female. He remained deeply attached to this subject, and in fact by the end of his life painted almost as many bathers as landscapes; they were followed by still lifes and portraits. With some exceptions, the bathers, too, are held in somewhat less esteem than the later work done from observation, and thoughtful critics have asked themselves why. Fry presumed that Cézanne, unlike, for example, Titian, simply did not have the capacity to summon up a serviceable image of the human body. But we may suppose as well that his imagination was constrained by the anxiety which it evoked, and in this connection we may remind ourselves of the evidence of his early poetry, in which impulse so easily arouses guilt or evokes punishment.

For Cézanne, then, creating came to rely on a broader kind of sublimation: in part the sexual and aggressive impulses were turned toward the more gentle sight of nudes bathing—in part the sheer vigor of his energies was directed toward passionate observation. (That he became deeply attached to observing is shown in part by comparisons of his landscape paintings with the views that served as their motifs. The correspondence is surprisingly close—Machotka's book shows a large number of them in color—and indicates attentive observation as well as an ability to capture his perceptions in a unified and self-consistent manner; see [Figures 2 and 3](#)). One may also say that Cézanne's successful creating meant finding a "conflict-free" sphere in which to work, that is, to work in the pleasurable sphere of observation rather than the ambivalent one of expressing fantasy.

Mature Styles

The concepts of need (as in the need to express fantasy or the need for fame) and defense (whatever one does to avoid anxiety brought on by needs) are necessary for understanding a painter's psychodynamics, but they are not sufficient. One must also note certain aesthetic purposes, which are fully conscious and less reducible to personal organization. In Cézanne's case there is certainly a search for a consistent style—a style that would be adequate to his subject matter, to the needs of his compositions, and to his perceptions. One must mention all three purposes, because it is perhaps for meeting them all so well, for the sense, as Fry puts it, that “the smallest product of his hand arouses the impression of being a revelation of the highest importance,” that he is known, admired, and indeed revered.

During the first 15 years of his career as a painter, Cézanne's search for style was serious and often successful, but neither linear nor smoothly progressive. Toward the end of the decade of the 1870s, however, it culminated in a new method of laying down touches of paint in parallel to create a surface at once lively and controlled, one in which every part of the canvas responded in some manner to every other part. At its inception, the method seemed useful for controlling the vividness of his imaginative subject matter, but by 1879–1880 he came to use it in still lifes and landscapes, above all to order his perceptions of the motif's complexities. He was justly proud of his achievement and somewhat unreasonably protective of it, and he resented Gauguin for adopting it for his own painting in 1881. Because short touches laid in parallel also formed a group with an upper and lower boundary at right angles to each touch, the method would help him align vague surfaces with other, much clearer ones. As Machotka shows, in landscapes it might serve both to order a chaotic expanse of foliage and to align it with one or another major structural line such as a tree trunk or bridge support. His paintings took on a character of unusual unity—a unity achieved not through repetition but through thoughtful opposition and internal resonance. We must remind ourselves that neither the conscious purposes nor the particular talents by which they are realized can be accounted for by psychological means—or indeed by any other means. The one is a mysterious consequence of thinking and feeling, and the other an apparent given, sharpened through experience. Cézanne's achievements cannot be understood through his personality alone, no matter how much his personality, and its development, help us understand his early interests and later renunciations.

The parallel touch—this cornerstone of his mature work—was further transformed in the mid-1890s into a system of smaller patches of color. They were sharply bounded on top, and depending on how they were needed in the composition, they would either overlap those above them, producing a receding surface, or move both in front of some and behind others, indicating a more disorderly surface such as foliage. In them, the parallel touch was suppressed, though detectable; it was the patches themselves that became the structural unit. These remarks should not be read as suggesting that Cézanne worked by formula, and even less that the formula might be learned. On the contrary, the parallel touches no less than the later patches were used flexibly for a variety of purposes

and variously for different subjects—indeed, they were needed neither in the still lifes nor in the portraits—and what they have in common is the sense they give us of revealing a rich and attentive perception of the objects they help portray.

The patches were the invention of a man of about 55 who was yet to paint his greatest work. It is one of the unanalyzable mysteries of the course of life that some artists—Titian and Cézanne among painters, and Verdi and Janáček among composers—should find not only a new style but a new inventiveness and productivity at a time when their physical energies might be thought to diminish. One can think of no common thread binding these artists, save for the obvious emancipation from their former work and willingness to search for new forms.

Cézanne's Achievements

Cézanne's turn from imagination to perception was a precondition of his best work, not the achievement itself. Seen externally, his work encouraged young painters who followed—in 1907, within a year of his death—to create their own systems of parallel touches and patches to analyze the surfaces of objects and recombine them in new ways to produce new objects.

From this way of seeing Cézanne's work, Cubism, the first revolutionary movement in painting of the 20th century, was born. If the Cubists misinterpreted Cézanne—by forgetting the function of color in creating form, for example—they nevertheless produced extraordinary achievements of their own. Seen internally, and apart from their effect on later painting, his achievements may be illustrated, though hardly encompassed, by looking again at [Figures 2 and 3](#). *L'Église de Montigny-sur-Loing* was painted in 1904–1905, about two years before his death, and shows a perfectly satisfying view of a northern French town's Romanesque church. Yet how much grander the painting is, even in its unfinished state, than the photograph. Cézanne has both accepted the view as he saw it and transformed it nearly imperceptibly: he has noted all the hard, flat surfaces—in relation to each other—and given us an indication of their local color, but he has also brought the receding diagonals—the edges of the various roofs—close to the horizontal.

This has the effect of making the scene appear as just flatter enough than it is to keep it close to the physical plane of the canvas, thereby reminding us that the painting is as much a physical object as it is a representation, and ultimately making the church and buildings appear more stable, even monumental.

Parenthetically, the patches he used here are not the ones previously described; here they are mere notations, strung out horizontally, and serve as a kind of shorthand to indicate what might later be elaborated more formally. But the unfinished state of the painting is neither unusual nor troubling. As with other unfinished canvases, because Cézanne has firmly placed the objects in relation to each other, and given us at least a hint of their color harmony, he has said in some ways all that needs saying: the painting has its full structure already, and if we should wish to fill in the blanks, we could, but there seems no need to. While such comparisons may help us see his achievements, they are not necessary. Fry's sense of

“revelation of the highest importance” in Cézanne’s paintings, although not put as felicitously by others, is widely shared. We may see it in a sense of the “rightness” and permanence of the objects he portrayed, and in the richness, tension, and ultimate resolution of his way of seeing them. His compositions are complex, but they are also richly resonant internally, their parts calling attention to each other, their oppositions resolved, and their details placed into a more encompassing order. In them one sees both the interconnections between things and, in Cézanne’s phrase (quoted by Gowing), the “logic of organized sensations” by which the painting process is governed.

Glossary

Attractor A region in the space describing the behaviors of a system toward which the system will tend to go and where it will tend to stay. *Strange attractors* characterize chaotic behavior and consist of confined trajectories that describe a system that is never in the same state and moving in the same direction twice.

Bifurcation A system's transformation from one type of system into another, for example, from a system with periodic motion to one in chaos. *Catastrophe* is a similar term, which generally refers to a seemingly discontinuous change in one system.

Chaos A class of dynamic behavior of deterministic systems characterized by sensitive dependence on initial conditions, diverging but constrained trajectories that imply unpredictability, and complex organization or structure.

Complexity is sometimes used as a synonym for chaos.

Dissipative systems Systems, such as living systems, that are using up energy.

Fractal A pattern characterized by similar structure at different magnifications, more roughly described as self-similarity at different scales; strange and other complex attractors generally have fractal structures.

Nonlinearity A term describing a relationship between two variables or a causal relationship between components of a system that is *not* strictly proportional and thus cannot be represented as a straight-line graph on ordinary graph paper.

State space A space containing representations of the possible conditions or locations of a system.

'Phase space' is sometimes used as a synonym for state space, but a location in phase space describes not only the current state of the system but also where it is moving next.

Systems theory Theory describing the behavior of composite entities composed of changing, interacting, and connected parts whose functioning emerges from the mutual influences of the parts.

Introduction

Chaos theory, more technically nonlinear dynamical systems (NLDS) theory, is an exciting, rapidly developing area of mathematics with increasing application in the physical, biological, and social sciences. Along with great metaphorical appeal, nonlinear dynamical systems can also add rigor and realism to human sciences; this article describes how they may help illuminate creativity, an elusive, sometimes near magical phenomenon that has defied simple explanations. Chaotic or near-chaotic systems can demonstrate surprising flexibility and adaptability. Despite connotations of 'chaos,' they also demonstrate order, complexity, and self organization. Some relatively simple, mechanistic, completely deterministic systems are capable of surprising, discontinuous, and seemingly unpredictable change. While this article is somewhat speculative, the connections it describes can hopefully be made more rigorous and tied to data about creative processes and products.

Potential Contributions of Chaos Theory to the Study of Creativity

Nonlinear dynamical systems theory is finding specific application to various human processes, including cognition, perception, motor movement, affect, learning, development, attitude formation, social behavior, self-evaluation, personality, and psychopathology. The field is changing rapidly as new

phenomena are explored with dynamic models and new data analytic techniques; these approaches are useful at both low-level (e.g., neuronal) and higher (e.g., societal) conceptual levels. Applications of dynamical systems ideas to psychology are still piecemeal, without systematic meta-understanding of how new models connect to more familiar theories, notations, and constructs. This article describes and suggests connections with well-known problems in creativity theory and research.

Definition of Nonlinear Dynamical Systems

NLDS theory describes the behavior of systems that, first of all, change with time; this is the meaning of 'dynamic,' referring to actions of forces producing motion. In addition, the theory describes systems where at least some of the relationships among components are nonlinear. In contrast much work in mathematics and the sciences historically focuses on linear systems, where change in one part results in proportional change in another and where the relationship between the magnitude of variable A and its effect on variable B can be represented graphically by a straight line. Linear systems have many desirable properties, including that effects can be computed as weighted sums of parts; they are often amenable to mathematical solutions that describe or predict their behavior over time. Research in psychology has emphasized such models, and, despite the importance of longitudinal work, cross-sectional or short-term relationships among variables, downplaying the passage of time. The correlation coefficient

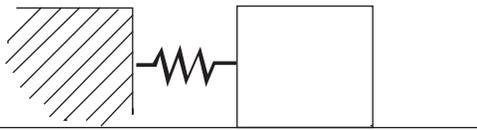

Figure 1 A simple linear dynamical system.

tests fit to a straight-line relationship between variables, often measured at a single time.

Figure 1 depicts a simple linear dynamical system considered as containing only one functional linear relationship. It is composed of a block resting on a frictionless surface, attached to a solid wall by a 'linear' spring whose restoring force is proportional to how far it is pulled or pushed. If the block is pulled and released, it oscillates back and forth in a smooth, identically repeating pattern, easily modeled and predictable as a simple function of time. In contrast, NLDS theory studies situations where the relationship between variable A and its influence on variable B is represented by some curve other than a straight line. Such relationships are surely the rule in nature, with linearity a useful simplification or special case. For example, discontinuous or all or none responses, such as reaching the threshold for a neuron's firing, are nonlinear ones.

Systems can be discussed in terms of mechanisms, processes, and paths. The previous paragraph and **Figure 1** describe the construction of a simple mechanism. Once a system is set in motion, we can describe the processes of its movement as well as the paths or trajectories its behavior follows. For systems that contain nonlinearities, behavior over time is often complex and fascinating; it can become more and more difficult to predict over time, even in the absence of technically defined chaos. Nonlinear systems are difficult to solve mathematically; this lack of 'analytic' solutions is one reason they have been avoided in many areas of science. However, this behavioral complexity lends them much current appeal; they promise ecologically valid explanations of real-world processes and appear particularly relevant to historically elusive abstract and practical problems. One reason for the onrush of interest in these systems is that computer technology has made possible iterative modeling and visualization of systems' behavior without solving them. Indeed, algorithmic, heuristic solutions to intractable problems, perhaps including 'being creative,' may make them more tractable.

Characteristics of Nonlinear Dynamical Systems' Mechanisms and Behavior

NLDS models are applicable to psychological phenomena for several reasons. They provide not-very-complicated and deterministic causal models compatible with observations of complex, patterned, often unpredictable behavior. Discontinuous, suddenly changing, or startling deterministic systems can seem disorderly, noisy, and random. Yet, despite resisting prediction, they also have surprising order and organization. The seemingly random development of snowflakes follows very strict symmetry and results in uniquely beautiful objects that, while nonidentical, have similar properties. Some features described here, such as the absence of analytic mathematical solutions, are associated with nonlinear but not necessarily chaotic systems; others, such as strange attractors, specifically apply to chaos.

Change with time

By definition, dynamical systems involve temporal processes. All human activity, of course, changes with time, and psychological and social systems exist in this context; important physical and cultural passages mark flux over the life cycle. Yet, most psychological research relies on short-term observations of these inherently long-term phenomena.

Closed and open systems

Systems are units composed of multiple linked parts; interconnection can be defined by rules and regulative processes. Cybernetic models of communication, control, and automation of the 1940s and 1950s contain many of the features of more recent theory. However, they tended to emphasize linear effects, limit themselves to simple causal loops (unidirectional not reciprocal), suppose that systems distribute accurate information throughout, and focus on stability, regulation, and homeostasis, rather than apparently less orderly behavior. Opponent-process (such as excitation and inhibition of neural circuits) and dialectical models (describing the synthesis of conflicting ideas) have been popular in psychology and biology. They are amenable to explanation via multiple interacting, possibly hierarchical processes and enriched by the complexifying consequences of nonlinear coupling.

Many current models assume closed systems, considered self-contained and isolated from other systems and the environment. In contrast, open systems are embedded and exchange inputs and outputs with the surroundings. Bodies transfer energy and information to the physical and social environment; they are also dissipative systems, constantly using energy. This has important implications for the complexity of human function.

Simplicity in structure with complexity in behavior

Relatively simple biological and psychosocial mechanisms, if including nonlinear causal relationships, are capable of complex and chaotic dynamics. The unpredictability, mysteriousness, sudden change, and robust adaptiveness of psychological processes can become comprehensible, rational, and potentially amenable to deterministic modeling.

Importantly, this nonlinearity does not generally refer to relationships between inputs and outputs of whole systems, or to discontinuities in outputs, but rather more narrowly to nonlinear linkages among internal components. Systems that include time delay are more complicated than ones with immediate response. As mentioned, nonlinearities are widely observed in the social sciences (e.g., the Yerkes–Dodson curve), but also commonly ignored.

The Behavior of Nonlinear Dynamical Systems

NLDS are capable of many different sorts of behavior, regular as well as chaotic. Some of the following characteristics apply specifically to chaos and complexity.

Unpredictability and sensitive dependence on initial conditions

Some systems are easily predicted, for example, the behavior of the linear device shown in **Figure 1**. However, others exhibit behavior where simple mathematical solutions are difficult.

There are two issues here. One concerns problems reducing motion of a system to a simple predictive equation, solving it analytically. This is true for many nonlinear systems, chaotic or not. The second is that at times nonlinear systems enter regimes of complexity or chaos. A defining characteristic of chaotic systems is sensitive dependence on initial conditions, where small differences in starting state result in large differences later. This is also true for small outside perturbations. Visualizing a system as following a trajectory over time, this means that paths through points that are very close together diverge radically later on, something with major implications for notions of cause and effect. Small influences can have drastic consequences, the usual meaning of the celebrated 'Butterfly effect.'

This reduces ability to predict the future. Unless the position and motion of such a system are observed exactly, one cannot know accurately where it will be later. Less-than-perfect observation of a chaotic system results in increasingly inaccurate prediction. While this unpredictability is superficially similar to the uncertainty principle, the Heisenberg principal operates only at extremely small subatomic scales. Uncertainty about future states of a macroscopic chaotic system does not come from minute quantum effects. Rather, this unpredictability is fully compatible with completely Newtonian physics, a consequence of the difficulty, given observational error and imprecision, of saying exactly where a system is and is going at a particular moment. If we knew these facts exactly, we could predict even chaotic systems. This distinguishes deterministic chaos from quantum uncertainty and from true randomness of stochastic, nondeterministic processes. What we call 'random' may be completely determined, yet still unpredictable. Galton's famous peg-board generates an approximate normal curve from marbles falling through pegs. For all intents and purposes their paths are governed entirely by the completely mechanistic and deterministic causal laws of Newtonian physics as they spin and bounce off pegs and wobble through air currents. Yet, the trajectory of a given ball is difficult to predict, sensitive to initial conditions and uncontrolled influences.

Social scientists generally employ deterministic models and remain puzzled by their failures at prediction and control for individual behavior, social policy, and intervention. Contemplating their own lives, many believe in free will, and also that they defy prediction by others, act spontaneously, and sometimes elude even *self* control (e.g., trying to change habits). NLDS models, while deterministic, also encompass unpredictability. This helps solve some methodological and philosophical problems; difficulties in prediction and control are just properties of real life. Yet, cross-sectional and locally linear psychological models are partially correct and still useful; overemphasizing linear relationships is a flaw easily corrected in principle. Many small and simple systems are probably involved in interesting psychological phenomena, and these subprocesses are coupled in under-studied and probably nonlinear ways.

Intractability

Much ongoing human behavior is intractable, not just in the sense of stubbornly eluding self-control and defying intervention. Certain classes of problems are notoriously difficult, apparently insoluble. Accounting for creativity is one. Dynamical systems may well help tackling these theoretical and

practical problems. It is even useful to seek out where older methods have failed, noting dynamics researcher and cardiologist Ary Goldberger's reference to problems "whose only apparent unifying theme was their 'resistance' to traditional models."

Catastrophic change and bifurcation

Another characteristic of dynamical systems is the possibility of sudden qualitative changes. These radical shifts are called catastrophes, and now popularly 'tipping points.' Seemingly discontinuous psychological changes include an alcoholic's 'falling off the wagon,' inspiration and brief encounters with the Muse, insight, and psychotherapeutic 'aha' experiences. Such processes are modeled by catastrophe theory, which has substantial overlap with NLDS theory. In addition to catastrophic state changes a system can also transform into a qualitatively different one, termed bifurcation; a system may shift from periodic to chaotic as values of its parameters are changed. This appearance of new systems is called 'emergence.'

Apparent regularity without identical repetition

Periodic regularity, repetition, and contained cycles characterize the stable oscillations or dynamic equilibria of classical dynamics, much beloved by physiologists and psychologists. Irregularity in oscillating systems has been attributed to random noise, measurement error, and extraneous variables. These are important concepts, but it is worthwhile asking when fluctuation represents data rather than noise, indicating a process is a candidate for nonlinear dynamic explanation. NLDS extend interest to bounded but irregular changes and unstable equilibria. Much human activity appears oscillating and generally bounded, yet only approximately regular, as well as capable of surprising. New research on normal and disordered biological rhythms suggests that both overregulation and underregulation can be maladaptive. And, the relatively bounded behavior of well-functioning organisms is sometimes adaptively chaotic, allowing reorganization, resistance to environmental influence or internal perturbation, and development.

Chaotic behavior and complexity

Not all NLDS are in chaos, but the possibility of chaos is one interesting feature. Because chaotic systems are ever-changing, never going through the same state with the same velocity (speed and direction) precisely twice, they can produce originality and constant innovation. They are characterized by the delightfully named strange attractors, regions containing bounded but always different (never-crossing) trajectories in phase space. (Phase refers both to the location of a system's elements at a given time and where it is heading next.)

Types of attractors

An attractor defines a region in phase space where a system tends to go and to stay. A fixed-point attractor represents a unique place that a system will approach. If friction is added to the system in [Figure 1](#), the block will eventually stop moving, a situation represented by a single position and no movement. One example of a periodic or limit cycle attractor is the motion of a clock pendulum. As long as the mechanism is wound, even if bumped the pendulum returns to the same regular swing. Such attractors characterize much of classical dynamics.

In contrast, chaotic systems have strange attractors. While a system orbiting a strange attractor may be in the same location at different times, it never does so with the same velocity; its trajectories in phase space do not cross. This describes the unpredictability of chaos, as very close but not identical paths diverge with vastly different outcomes later. Strange attractors, bounded but never repeating, include elements of both order and disorder, divergence and convergence. Antithetical to both stasis and repetition, behavior around a strange attractor is constantly new.

Dissipative systems and the edge of chaos

The edge of chaos refers to systems not yet settled around a strange attractor or the order characteristic of chaos. This represents the edge of order, like the point between freezing and melting prior to the formation of a snowflake. A related concept involves 'dissipative' systems that use up energy, also termed far-from-equilibrium systems. A dissipative system is illustrated by someone falling and running forward, constantly off-balance. Walking is similar to this; stopping suddenly demonstrates that halting really is catching a fall and does not result in stillness. Even standing in one place contains novel possibilities.

Scaling, symmetry, and self-similarity: fractal phenomena

Strange attractors also demonstrate interesting structures, including fractal patterns with properties of self-similarity across different scales. Similar behavioral patterning over different instances, temporal scales, and locations in space is related to Wittgenstein's 'family resemblance concepts' and to the notion of artistic 'style' across different works and over a career. Observations of similarity across scale are common in clinical psychology in miniature occurrences in the therapy hour and recapitulations of old interpersonal patterns, forms of personal self-similarity. Some theories describe art as 'working through' a psychological or technical problem. Freud noted that this mastery-oriented 'working through' and self-defeating 'repetition' are similar – healthy versus unhealthy – cycles; they may represent periodic versus strange attractors.

Self-similarity but not self-identicalness also provides an account of consistency in personality. Individuality may represent personal complexity, detail visible when one is known deeply and across longitudinal ebbs and flows. Consistency exists in the face of the stark self-contradiction important in the human soul and the material of much literature; it occurs at different scales and does not mean people always do the same thing, even in similar situations. Viewing personality styles as strange attractors with fractal structure reconciles personal identity with cross-situational and within-subject fluctuation and originality.

Fractal patterns also occur in temporal phenomena like a faucet dripping. They suggest leaving a purely unidirectional view of time for a combination of linear and cyclic pictures,

encouraging diversity in the Kantian basics of time and space. From this perspective, regular and seemingly periodic eras are regions around attractors that we enter, orbit, and leave. While cycling, life appears repetitive, with nearly symmetrical beginnings and endings and narrative-like episodes of rising and falling action. Then the story changes or reverses, and our lives depart for new regions.

Self-organization

Some, notably Stuart Kauffman, have emphasized chaotic systems' self-organization, including properties of symmetry and self-similarity. They argue for a special sort of systemic order, 'order for free,' occurring even as systems dissipate energy. These visions of order and organization indicate how 'progress' may be reclaimed in the face of entropy.

Nonlinearity Can Make Even Simple Systems Complex

Figure 2 illustrates a small nonlinear mechanism – what I call a Somewhat Complicated System (SCS) – composed of two simple systems from Figure 1 coupled by a nonlinear 'hard' spring in the middle, whose restoring force is represented by a function of the form $F = k_1x + k_2x^3$. With certain parameters this system exhibits chaotic behavior; it serves as an analogue of two, nonlinearly coupled self-regulating systems, a dual homeostat with possibly unpredictable behavior.

Applications of Nonlinear Dynamical Systems Theory to Creative Process and Product

The remainder of this article explores how concepts from NLDS are applicable to core problems in creativity theory and research.

Nonlinear Dynamical Systems in Creativity and the Arts

Temporal changes

Creative products, however spontaneous, necessarily emerge in dynamic process. While a flash of insight seems instantaneous, inventing unfolds over time. Creative activities have been described as comprising stages of generativity and consolidation, incubation, and elaboration. Psychological 'regression' and the association of ideas also unfold temporally. Creative productivity develops over a life span as work's meaning and realization are modified with cultural and historical context, the creator's experience and life stage, and shifts in approach and technique. Genres and movements emerge historically and are pushed along by generations of participants. Researchers including Colin Martindale, Dean Keith Simonton, and Sidney and Ethel Blatt have studied changes over historical time periods. Yet, while speaking of the process of creating, hence

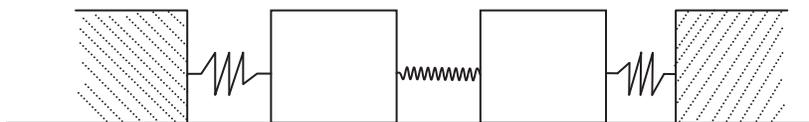

Figure 2 A nonlinear dynamical system consisting of two systems from Figure 1 coupled in the middle with a nonlinear spring.

invoking time, empirical creativity researchers often take static trait (not transactional) approaches, treating divergent thinking as an individual difference instead of a process of divergently solving problems. While speaking of the path of a career, we may still focus on 'completed' works that – once produced and 'tweaked' – change relatively little, although their influence on audience and culture resonates.

Systems and open systems in creativity

The creative process

Even working in isolation the creative individual, not completely self-contained, is embedded in a social milieu and responds to wider cultural problems. This defines an open systems phenomenon. The creator, the artistic medium, and the problem to be found or labored on; economic factors, society, technology; other people, including caretakers, critics, competitors, cronies, colleagues, grant managers, groupies, muses, patrons, and roadies: all have roles. Creative endeavors involve context-sensitive adaptation to fluctuating environments. This denotes reciprocal feedback loops connecting creator and public, product and audience response. Dialogue is a feature of successful work, where a piece of art 'speaks' to the audience; the viewer or listener is taken by the hand and led to see, understand, and even change. Communicability may distinguish 'true art' from 'psychotic art,' related to Frank Barron's 'Ego strength,' which may differentiate creativity from psychopathology.

There is also interchange between perceiver and perceived; the creative individual is modified while attempting to use the social or natural world as theme, inspiration, or medium – accommodating as well as assimilating. Several definitions of creative activity include the term 'adaptive,' including Guilford's 'adaptive flexibility' factor and adaptive regression in the service of the ego. 'Adaptive' can mean 'useful' but also implies that creative activity is connected to reality and responsive. It also includes self-stimulation and internal feedback; Tobi Zausner notes 'autocatalysis' as the artist responds to the work itself as well as environmental feedback. This is related to Maturana, Varela, and others' 'autopoiesis,' the self-creation of living systems.

Systems properties of creative products

New productions emerge from multiple interacting processes directed at interlocking problems. Two or more factors influencing one activity, such as competing expressive modes or coupled strategies, produce entanglement in a system. Given nonlinear linkages, a combination of simple processes – a Somewhat Complicated System – can show complex behavior, deep and textured forms of life. 'Intelligent' behavior results in new approaches to robot navigation employing simple rules or heuristics, not complete internal maps of the robot's world. This is a shift from intensive computation and complicated mental representation to simpler perception-action schemes – from 'top-down' executive function to 'bottom-up,' distributed and partially autonomous coupled processes. A robot that 'avoids obstacles,' 'follows walls,' and 'finds doors' can navigate without internal maps. This is similar to the Santa Fe Institute 'Swarm' project's modeling of collective behavior.

Similarly, a creative product can emerge from small and unrelated problems or performances, not necessarily a grand totalizing design imposed from the top. Evolutionary biologist

W. D. Hamilton suggested that modular systems with different agendas can evolve separately, accounting for organisms' robust but sometimes contradictory strategies and goals, and for the existential foundations of human life. Frederick Abraham cites Howard Gardner's creativity model with three coupled processes involving individual, discipline, and the judgmental society. Coupled push-pull creativity models are rich places for researchers to consider NLDS approaches, and loose versus tight coupling among subsystems represents a crucial parameter. Nonlinearity has a place in input-outcome relationships, starting with "more of a good thing is not always better." Art, science, and philosophy must sometimes resolve opposition and contradiction; this can be understood with competing and coupled subsystems with nonlinear 'dose-response' functions.

Simplicity and complexity in art and its making

The creative product itself displays simple origins and complex realization. A poem's simplicity manifests on the surface of the page, yet its depth can make both inner life and external 'fate' intelligible. The creative act may arise from simple actions that, put in motion, crystallize an artistic product.

Characteristics of the Creative Process and Product in Relation to the Behavior of NLDS

Unpredictability and sensitivity to initial conditions

The unpredictability of creative work means its trajectories cannot reduce to simple equations; insight emerges from heuristics rather than algorithms guaranteeing solution. (Heuristics represent inexact procedures without guaranteed results that can be highly efficient and useful.) We can provide guidelines and procedures to assist creative brainstorming but not write a book for cooking up the ideas themselves. Indeed, if we found this cookbook we might not call the results creative. This is not to say that creativity resists modeling or implementation with deterministic processes; however, techniques are iterative, their results generally not predictable in advance. Behavior can come from mechanistic processes and still be surprising as even nearby states diverge radically.

The creativity question as intractable

This article has discussed two forms of intractability, both relevant. First, facilitating creativity is difficult; it may even be paradoxical to push for a creative solution, not allowing it to appear. Second, the study of creativity tantalizes theorists and researchers. One hint that its puzzles might be amenable to NLDS comes from this very difficulty of its description and essence.

Catastrophic change, bifurcating systems, and emergence

Creative phenomena exhibit both near-regularity and wild fluctuations. Near-periodic creativity occurs in innovation during periods of normal science. In contrast are qualitative leaps in ideas and artefacts during insight and illumination, when genres break, and in scientific revolutions. This is also true of inventive and apparently self-initiated action. Psychologist Phyllis Perna speaks of cycles of disorganization and reorganization.

Bifurcation refers to the transformation of one type of system into another, for example, from periodic to chaotic; Zausner writes of creativity comprising subsystems bifurcating

into a new order. The transition zone at the edge of chaos near a new chaotic system may be especially important. Chaotic systems can also settle back into stable attractor regions. Transitions from inspiration through consolidation and then to implementing a creative program may represent bifurcations.

Repetition and near-periodicity in creativity

Repeated jousts at the same problem may be necessary. Psychoanalytic ego psychologists described play as repetition aimed at mastery and working through, and many, including Sandra Russ, have commented on the inventiveness of children's play and the play-like, restitutive aspects of creating for adults. Playfulness is part of the 'regressed' or developmentally prior quality of some adult creative work. Whether play or art solve particular psychological problems or represent neurotic repetition can be understood with different attractors.

Chaos, complexity, and creativity

Several characteristics of chaos are seen in creative process and product. Zausner again notes how artistic work is very sensitive to stimuli and speaks of the role of the 'inconsequential' in art, the unpredictable but not random influences. Relevant to top-down versus distributed processing, she also asks, "Doesn't the artist have a plan for the painting?" A work of art may be more emergent phenomenon than planned progress toward a prearranged point. This again speaks to heuristics and what economist Herbert Simon calls 'satisficing,' opposed to either 'optimizing' or 'maximizing,' which both may be inherently or computationally impossible. Frederick Abraham speaks of 'self-organizational bifurcations,' observing that chaos and instability can facilitate creativity. The late poet laureate Howard Nemerov spoke metaphorically of chaos as the primordial order before creation. Ben Goertzel, Ronald A. Finke, and others are describing chaotic logic and cognition. Theorist and clinician Michael Butz also refers to psychic swings not strictly speaking periodic, with structure emerging from chaotic behavior.

The creative process must avoid stasis, stagnation, and premature closure, capture by fixed-point or limit-cycle attractors, and the strictures of an imperious environment. Chaotic systems may demonstrate healthy flexibility, adaptability, readiness for change, resistance to environmental entrapment, autonomy, and openness to new information. Neurologist Walter Freeman said, "Chaos provides the system with a deterministic 'I don't know' state within which new activity patterns can be generated . . ." (Skarda and Freeman, 1987: 171).

Attractors in art

Attractors may be useful for describing creative products and styles. The vicissitudes of creative process can be viewed as trajectories in phase space – the positions and directions of multiple problem-finding, problem-solving, expressive, and generative processes. When a trajectory is near some particular attractor, work remains within a genre, style, school, theoretical orientation, paradigm, convention, or norm; style is an attractor in a region of phase space. Patterned themes and motifs within a single work can also be understood as attractors. This includes rhythm, oscillation, progression (cycles of fashion, rediscovery of old ideas, recapitulation of themes within a single work), the entrainment and synchronizing of different systems (adoption of a theory or

artistic approach, contained progress in normal science, or multiple near-simultaneous discoveries), and the emergence of new paradigms when revolution is truly in the air. Individual creative episodes may also be viewed in phase portrait terms.

Creativity and dissipative systems: the edge of chaos

Ruth Richards, Frederick Abraham, and others are exploring the importance of operating at the edge of chaos to creativity and evolutionary adaptation. Conditions that foster brainstorming may represent cognitive sets or work settings somewhere between stasis (or periodic behavior) and chaos. Csikszentmihalyi's 'flow' lies between boredom and anxiety. The edge of chaos, observed in dissipative systems, also sheds light on transitional or 'liminal' phenomena, psychological or cultural frontiers important to play, phantasy, and psychotherapeutic change. Zausner views artistic products as manifesting order, while the creative process is dissipative, with the uniqueness of a work coalescing from dissipative structures. She also comments on potential disorder, with a fine line between 'breakthrough and breakdown'; creativity and psychopathology may sometimes be very close together. Similarly, Aldous Huxley once wrote how the mescaline experience was poised between 'heaven' and 'hell' (two attractors?), and David Schuldberg speaks of both 'giddiness and horror' in the creative process.

Symmetry and fractal properties in creativity

Fractals can depict the self-similar patterning of trajectories around chaotic strange attractors. Zausner notes how a person's creative periods also appear self-similar, with successive inventiveness and reflectivity; this may account for associations between alternating mood states (including bipolar affective disorder) and creativity. In addition, works of art – as opposed to reproductions and cover versions – are unique; fruits of creative process have unpredictable but not disorderly shapes. An artist's style is self-similar. Works bear family resemblances to each other, and this kinship reflects their birth process.

Fractals also have aesthetic qualities. They are similar (although not identical) at different magnifications. To a beach connoisseur Washington beaches are recognizable (and distinguishable from Cape Cod beaches) at many scales: in aerial photographs, viewed from a headland, walking by the water, and even in tiny fringes around a tidepool. Miniatures have an important relation to creativity; a symbol, song, a statistical model, and a mathematical notation can all be miniatures. Levi-Strauss stated that "all miniatures seem to have an intrinsic aesthetic quality," precisely because they are small and complete. Similarly Ruth Richards notes how people find fractal patterns beautiful, are drawn to things, like waterfalls and beaches, that instantiate them. Mathematical analyses of Jackson Pollock's 'spatter' paintings suggest a fractal organization not found in 'pseudo-Pollocks.'

Another issue concerns ambivalence between symmetry's sometimes inherent beauty and the contrasting role of imbalance and complexity. Creative individuals may choose complicated and asymmetrical forms and tend to prefer Barron-Welsh Art scale figures that are asymmetrical and complex. Creativity involves both order and symmetry breaking; nonidentical fractal similarity helps reconcile these ideas.

The creative process as self-organization

Creativity involves self-organization, related to continually 'self-producing' and 'autopoietic' structures. Creativity may also be dissipative, leading to the self-organization of artistic products. Musical works, new theories, and novel solutions to engineering problems can be viewed as emergent structures. Emergence provides a view of how new information is produced by culture.

Nonlinearity and Creativity

Creative products, no matter how complex, can perhaps be understood as artefacts emerging from relatively simple psychological and sociological processes. This will require systems involving coupled, dialectical, or opponent processes, along with nonlinearity. In this Somewhat Complicated Systems account of creativity simple mechanisms and processes produce complex and extraordinary results. Some nonlinear psychological relationships have already been mentioned; Richards and others have also demonstrated 'inverted-U' relationships between creativity and psychopathological characteristics, and this may also hold true for positive and negative affect. More basically, adaptiveness, health, and well-being do not generally follow in simple linear fashion from positive behaviors or virtues; a medium is not always happy. Thresholds, floor and ceiling effects, responses that level off or drop, time delay, double-edged personality characteristics, and interactions between two or more causal variables all introduce nonlinearity.

Simonton, David Harrington, and others have commented on nonlinear relationships within creativity. The nonlinear model in [Figure 2](#) provides an example if we define its horizontal axis as ranging from 'intrapsychic-focus' on the left to 'environmental focus' toward the right. The blocks then trace oscillating paths of incubation, 'woodshedding,' and potential access to 'primary process' at the left, with dissemination, performance, and getting (perhaps suffering) critical feedback to the right. Strange attractors in phase portraits of the blocks' motion would indicate constrained novelty; the system can also settle into stable, repetitive, less creative states.

Specific Phenomena in the Creative Process

Intuition

In *Being There* neuroscientist Andy Clark touts environmentally engaged cognitive heuristics (discussed above) and modular low-level problem solving over top-down, executive-dominated thought. Induction and insight may be similar. Mandell and Salk describe how "structure arises autonomously from the superficially random motions of complex cooperative systems [which] suggests that 'intuitive' ... properties may be the source of more linear 'reason.'" Our apparent rationality may arise from intuition, not vice versa.

Brainstorming, Improvisation, and Juxtaposition

Recombination and going beyond information given are used in brainstorming techniques and facilitating induction. Similarly, improvisation refers both to inventiveness and to a type of performance. How does it occur? Juxtaposition,

superimposition, accretion, and Albert Rothenberg's 'home-spatial' thinking all provide routes to new ideas. These represent different combinatory forms and the 'blind variation' of D. T. Campbell's account of creative cognition. Juxtaposing and combining distinct or diverse elements, sliding unrelated concepts past each other, examining match, mismatch, and interesting features, noting when contrasts create conceptual connections, and discarding unproductive or unpleasing correspondences (part of Campbell's 'selective retention'), all produce new wine in old skins. Richards discusses the importance of experiencing and reconciling contradictory moods. Superimpositions are temporary and casual; they may initially display playful, even hostile and destructive attitudes toward more 'sensible' or accepted combinations. 'Contamination' of concepts on the Rorschach inkblot procedure is similar; noun-noun combinations are important in the speech of young children. Juxtaposition occurs in nonhierarchical combinations in techniques of collage and assemblage; these do not strive for superordinate categories or top-down hierarchy, and combinations can initially be force-fit.

Bricollage, a handyman's improvisational problem-solving usually directed at a repair, is both top-down and bottom-up. There is an end in mind – to repair a broken object or solve a problem; it utilizes planning but relies on heuristics and not the textbook solutions of service manuals, which require factory-compatible parts. Materials and tools may be used in ways not originally intended. Bricollage is also related to nonnarrative expositional forms, where elements and moods are laid on each other in sequences or admixtures, where story does not follow standard progressive forms.

Temporal Change in Cultural Milieu

Cultural diffusion, spreading innovation, individual acquisition of expert performance all unfold in time. So does grasping a new idea or paradigm, trying it, and making it one's own. These processes include dialectical acceptance and rejection, accommodation and assimilation; we can view creativity as resulting from struggle between adaptive and conservative processes. Martindale and Simonton discuss how new ideas, tastes, aesthetic values, and movements change over time. Martindale noted how fashion tends to make incremental changes; when a style has gone (what later observers declare) 'too far,' a trend reverses. Men's ties become wider, then progressively narrower, and again. Such oscillation can be modeled with both classical and nonlinear dynamics. But, fashion may involve chaotic rather than strictly periodic attractors just because history does not precisely repeat. Styles never return exactly, even in nostalgia; irony and distance, sentimentality and reclamation of youth, are all wrapped up in 'retro' fashion. The leg warmers of 2009 were not quite the same as the leg warmers of 1989; if a 'revival' is a strange attractor, 'old school' is also recognizably not quite the past.

Evolutionary Epistemology and Emergent Order: Creative Cognition

Evolutionary epistemology studies how new knowledge emerges analogously to the evolution of biological structures

through Darwinian natural selection. Chaos theory has found applications in evolutionary theory, and it is fruitful to pursue how mutation, selection, and adaptation can be applied to – using Dawkins' term – 'memes' of creativity. As creative cognition 'channelizes' (in evolutionary biologist C. H. Waddington's image) in particular paths, this implies emergent order. These paths can be viewed as basins of attraction in 'fitness landscapes' of ideas. Models of these processes have been constructed with neural networks and other techniques, for example, simulating schizophrenic thought. Particularly relevant is the experimental work of social psychologist Robin Vallacher on the temporal formation of attitudes as attractors, also applicable to problems in insight.

Conclusion

Further Steps in a Dynamical Systems Program for Creativity

Creativity theorists will do well to consider how dynamical models illuminate originality. Psychological systems containing a term for time, that include internal nonlinearity or use dialectical processes are all places where new theories and techniques can be applied. Systems whose behavior shows bounded but imperfect repetition, temporal development, or qualitative jumps all deserve further study. The referents of many psychosocial terms relevant to creativity are dynamic ones. How does regression in the service of the ego unfold over time? How does a 'remote associate' on Mednick's test emerge? What is the trajectory of a career in creativity or leadership? What is the phenomenology of transitions from incubating to elaborating, from boredom or anxiety to 'Flow'? How is a 'creative crisis' resolved? Descriptive qualitative dynamics will point to new and testable models.

A Preoperational View of the Dynamics of Improvisation

This article concludes by arguing for a relationship between creativity and relatively simpler forms of thinking, akin to Piaget's preoperational thought. The juxtapositions and recombinations mentioned above are similar to classification strategies used by preoperational children, who use one dimension at a time to sort objects that can only be compared exhaustively with more complicated schemes. The child cannot hold distinct classificatory dimensions simultaneously; schemes fluctuate and compete. A creative adult's incomplete approaches are also heuristic strategies, practical wisdom but not theory. Real objects do vary on too many dimensions for complete categorization, even by competent adults; we may need to construct more manageable, less exhaustive accounts of our experience. We may look down on the child's dimension-reducing, but when we make sense of our own lives, planning, steering, and rational control are constrained, with significant blind spots. These are limits to how useful abstractions can be.

Living as we do through everyday language, we use incomplete but handy views of the world. We are successful because we deploy many of these simple, humble heuristics in parallel, and we use them all the time. Our tools for knowing are not limited, in the sense that their limitations could be avoided or they could be substantially improved upon. Inexact everyday cognition is limited only in not living up to grand phantasies

of comprehension, prediction, and control. Real life requires bottom-up improvisation in real time, filled with what Richards calls Everyday Creativity. Because we use multiple heuristics with nonlinear effects, our attainments are not easily decomposable into components, nor reversible like the schemas of Piaget's formal operations. Tobi Zausner speaks of the irreversibility of painting, situating it outside formal operations and within the realm of dissipative systems.

When chaos is involved, even simple systems can make complex products. This is connected to Wittgenstein's accounts of the limits of language. In everyday use language does not have much trouble living with big ideas, as long as we refrain from philosophizing or psychologizing. We *inhabit* big ideas and grapple with existential concerns; life's practical techniques do not guarantee solution, putting limits on social science and denying a truly encompassing, exhaustive view of the good life. Yet, this does not limit what is *possible* in everyday life and in creativity. The everyday is determined yet unpredictable, complex but also organized, self-similar day to day, sometimes very beautiful. Without a guaranteed solution we extemporise, lacking the unattainably huge computing power for a stable big picture or for navigating a steady course toward a comprehensive goal. Using benchmarks and approximations, our apparent mental steadfastness is really a falling forward, far-from-equilibrium, dissipative, always unstable. We *must* improvise.

Creativity across fields is related to the aesthetic qualities of everyday life. Although not reducible to fool-proof procedures, everyday life has striking beauty and some order, all amidst constant flux. Everyday living requires backing away from enlightenment ideas of progress and perfection to embrace – and create – the rough-cut beauty of our real worlds.

Charlie Chaplin 1889–1977

Chaplin's Life and Work

Charlie Chaplin was born Charles Spencer Chaplin on 16 April 1889, in London, England. His parents were both entertainers in the music-hall tradition: his mother was Hannah Chaplin, a singer and actress. His father was Charles Spencer Chaplin Sr., a vocalist and actor. As a small child Chaplin lived with his mother (his parents separated when he was still very young) and his half-brother Sydney, in Lambeth, London. Chaplin's father was an alcoholic, and died of alcohol related causes when Charlie was 12. Charlie and his father had little contact except for a few brief meetings and a short period during one of his mother's illnesses when the brothers lived with their father and his mistress. Although Charlie hardly knew his father, he made a big impression on the boy, as did his mother, whom he adored.

The Chaplin family's fortunes waxed and waned during Chaplin's childhood, and he spent much of his childhood in abject poverty, starving, and even living on the streets for a brief period. His mother was mentally fragile, as was his grandmother who also suffered mental illness. Chaplin's mother was admitted several times to asylums during Chaplin's boyhood leaving Charlie and his brother in workhouses at Lambeth, in South London and The Central London District School for paupers in Hanwell. The young Chaplin brothers had a close relationship and gravitated to the music-hall while still very young, in order to survive. They learned to be both entrepreneurial and opportunistic in the tough and cruel circumstances of their upbringing. Chaplin's early years of poverty, homelessness and hunger were a great influence on his later characters, films, and political beliefs.

Chaplin demonstrated stage presence, a natural aptitude for impersonation, and dancing prowess when he was a young child. He joined the Fred Karno troupe in 1910, and when the troupe toured America in late 1913 Chaplin's act was seen by Mack Sennett who hired him for his studio, the Keystone Film Company. Sennett mentored the young Chaplin and Chaplin sought out role models, mentors, and people he could learn from throughout his life. Chaplin's pictures were popular successes, and he was one of Keystone's biggest stars. Keystone was Chaplin's creative 'infancy.' Chaplin learned about film making and developed his tramp character while he worked at a phenomenal rate completing 34 short films in one year. Chaplin's 'tramp' gained enormous popularity among cinema audiences all over the world. He was known as Charlot in French speaking countries, Italy, Spain, Andorra, Portugal, Greece, Romania and Turkey, Carlitos in Brazil and Argentina, and Vagabond in Germany.

While at Keystone Chaplin was entrusted with directing and editing his own films. Chaplin's brother Sydney joined him in 1915 and helped Charlie sign a more favorable contract with Essanay Studios. Chaplin's time at Essanay was his 'adolescent' creative period; he further developed his cinematic skills, and

added new levels of depth and pathos to Keystone-style slapstick. His films became much more ambitious, being twice as long as a typical Keystone picture. Many of the films he made with Essanay are classics including *The Tramp*. They show Chaplin's nascent talent and many of the ideas that were to come to fruition in his later mature period of film making.

Chaplin sought complete artistic control over his products from very early in his career. At Essanay he became a full-blown celebrity, as he was very popular and he made himself and those around him wealthy. Chaplin developed a loyal stock company, including ingénue Edna Purviance and comic villains Leo White and Bud Jamison.

The silent tramp pantomime character Chaplin invented was central to his success. During Chaplin's period immigrant groups arrived in America in waves, from diverse countries and creeds. Silent movies were able to cross all the barriers of language, and so Chaplin had unprecedented popularity. Everyone could understand and relate to him. Chaplin's Tramp enacted the difficulties and humiliations of the immigrant underdog, the constant struggle at the bottom of the American heap. The Tramp would triumph over adversity in his films, but his life remained essentially the same so he stayed in touch with his audience and retained their sympathy. In addition Chaplin himself personified the rags to riches story of the American mythology of opportunism and success.

From Essanay Chaplin moved to the Mutual Film Corporation in 1916. Mutual paid Chaplin \$670,000 to produce a dozen two-reel comedies. He was given near complete artistic control, and produced twelve films over an 18-month period that rank among the most influential comedy films in cinema. Practically every Mutual comedy is a classic: *Easy Street*, *A Dog's Life*, *The Paunshop*, and *The Adventurer* are perhaps the best known. This period in Chaplin's career was his happiest, although he found the stringent production schedule demanding and restrictive, especially because his method of film-making involved improvisation and repetition, which were both expensive and time-consuming.

At the conclusion of his contract with Mutual in 1917, Chaplin signed a deal with First National to produce eight two-reel films, which First National financed and distributed from 1918 to 1923. Chaplin enjoyed much more creative control over all aspects of the filming process including production and he built his own Hollywood studio. He was also able to perform at a more relaxed pace that allowed him to focus on quality. Although First National expected Chaplin to deliver short comedies, he expanded most of his personal projects into longer, feature-length films, including *Shoulder Arms* (1918), *The Pilgrim* (1923), and the feature-length classic *The Kid* (1921), which introduced a strong element of pathos and sentimentality to silent movies which was innovative at this time. In 1919, Chaplin along with other celebrities (Mary Pickford and Douglas Fairbanks Sr.) cofounded the United Artists film distribution company in order to escape

the growing power of film distributors and financiers in the fast developing Hollywood studio system. With this move to United Artists Chaplin assumed complete control of film production. His independence was crucial in allowing him to achieve artistic maturity.

Chaplin made his mature masterpieces at United Artists. They were all of feature film length, beginning with an atypical drama in which Chaplin had only a brief cameo role, *A Woman of Paris* (1923). This was followed by the classic comedy *The Gold Rush* (1925). In an iconic scene that tells a great deal about Chaplin's techniques, he turns starvation into a joke, by eating his shoe: he picks at the nails of his boot as though they are 'the bones of a delicious capon' and eats the laces as though they were spaghetti. His companion imagines he is a chicken and chases him around the room, wishing to eat him. This idea, Chaplin said, came from stories he heard about American pioneers starving and dying of hunger and cold, and resorting to cannibalism, and roasting their moccasins to relieve their hunger. Chaplin claimed that comedy was paradoxical because it arose from tragedy, which stimulates ridicule. Laughter through ridicule was defiance against the unassailable forces of nature which might otherwise make people go insane.

After the arrival of sound films, and while still with United Artists, Chaplin made *The Circus* (1928), *City Lights* (1931), as well as *Modern Times* (1936) before he committed to sound. He was nominated for an Academy Award for 1927–1928 for best actor and best comedy picture for *The Circus*. However the Academy withdrew his name from competition and gave him a special award "for versatility and genius in writing, acting, directing, and producing *The Circus*." *Modern Times* and *City Lights* are considered to be prime examples of Chaplin's art. Both are sophisticated pieces of symbolic film-making that were essentially silent films scored with Chaplin's music and sound effects. Voice is heard in *Modern Times*, but it is mediated through technology, and Chaplin's own voice is heard in the 'nonsense song' at the end of the movie. *Modern Times* is a sublime critique of Chaplin's difficult situation *vis-à-vis* the invention of the 'talkies,' as well as being a humanitarian commentary on the dehumanizing effects of rampant industrialism. *City Lights* is billed as a comedic pantomime, but is a complex symbolic rumination on film celebrity, wealth, and the philosophy of communication (especially sound and vision).

Chaplin's first dialogue picture, *The Great Dictator* (1940), was an act of defiance against German dictator Adolf Hitler, Nazism, Anti-Semitism and Fascism. It was filmed and released in the United States one year before the United States abandoned its policy of neutrality to enter the second World War. Chaplin exploited the similarities between Hitler and The Tramp (especially the little moustache). He played the role of Adenoid Hynkel, Dictator of Tomania, clearly modeled on Hitler. The film was seen as an act of courage in the political environment of the time, both for its ridicule of Nazism and for the depiction of Jewish persecution. Chaplin was nominated for best writing and best acting Academy Awards for *The Great Dictator*, but he did not win.

Chaplin's personal life and fortunes were followed voraciously by the media. He was married three times, first to Mildred Harris, with whom he had a son who died shortly after being born, and the second time to Lita Grey, with whom

he had two sons. Both women were only 16 when he met them and both brief marriages were spectacular failures, ending in bitter and acrimonious divorces. He had several other close relationships with women before marrying Oona O'Neill when he was 54 and she was 18. They had eight children in a long and successful 35 year marriage that lasted until his death. He also enjoyed successful relationships with Edna Purviance and Paulette Goddard, with whom he remained life-long friends.

Chaplin remains possibly the most universally famous mass celebrity figure in history, and although he was feted as a genius he was also eviscerated by the media for perceived personal and political transgressions. Chaplin was often associated with left-wing politics in America, and knew many communists, but he also had friends amongst the wealthy and powerful such as William Randolph Hearst, Winston Churchill, and H. G. Wells. In the 1940s United States, his political views (in conjunction with his influence, fame, and status in the United States as a resident foreigner) were seen by many as radical, and this was exacerbated because although he was a resident from 1914 to 1953, he never became an American citizen. During the era of McCarthyism, Chaplin was accused of 'un-American activities' as a suspected communist and when, in 1952 he left the United States for what was intended as a brief trip to the United Kingdom his reentry permit was revoked. His final film in the United States, made when he was feeling persecuted in America, was *Monsieur Verdoux* (1947), also considered to be one of his finest works. Although ostensibly about a serial murderer it is also widely understood to be a critique of capitalism and American foreign policy.

Chaplin made his home in Vevey, Switzerland. He briefly and triumphantly returned to the United States in April 1972, with Oona O'Neill to receive an Honorary Oscar. Chaplin's final films were *Limelight* (1953), *The King in New York* (1957), and *A Countess from Hong Kong* (1967).

Chaplin was a musician, composer, and choreographer as well as film-director and actor. He composed scores, wrote songs, and choreographed most of his films. Two of his most popular songs are 'Smile' and 'This is my song.' Chaplin's score for *Limelight* won an Academy Award in 1972. There was a delay in the film premiering in Los Angeles due to Chaplin's unpopularity in America in the early 1950s and so the movie became eligible decades after it was filmed.

In his later career Chaplin wrote extensively on his life. He also wrote original music compositions and scores for his silent pictures and rereleased them. Chaplin's last completed work was the score for *Woman of Paris*. He was knighted at age 85. Sir Charles Chaplin died in his sleep in Vevey on Christmas Day 1977.

Chaplin's Creativity

Much can be learned about creativity by examining the life and art of Charlie Chaplin as he exemplified the art of 'creative living.' Scholars have often used psychoanalytical theory to explain Chaplin's creative imagery in his movies. Chaplin has been put 'on the couch' not least because Chaplin himself has said that *pain* was the source of his comedy, and that comedy was a 'strategy for living.' Comedy was, quite literally,

Chaplin's 'therapy' to help him overcome personal and professional challenges. Both *Modern Times* and *City Lights* for example exemplify Chaplin turning his personal difficulties into art of almost mythological proportions. The famous scene of Charlie being ingested into and then expelled from the great machine in the first stunning sequences of *Modern Times* is widely understood as being Chaplin's commentary on his own situation *vis-à-vis* being chewed up and spat out by the film industry.

So, one source of Chaplin's creativity was his autobiographical processes, but a number of other factors, both external and internal contributed to Chaplin's creative life. Two major external influences were music-hall from England and Keystone in America. The theatre world into which Chaplin was born was the outcome of several centuries of entertainment tradition and evolution. Music-hall gave Chaplin a background in the comedic arts but he recognized the limitations of its conventions and found it restrictive. Keystone also placed very rigid prescriptions and conventions around what was considered to be funny – the chase. Chaplin was never satisfied with restrictions and was always looking to extend form and technique in his craft.

Another important external influence was American culture and history: Chaplin's Little Tramp was a peculiarly American figure. Chaplin had an ambiguous and contradictory place in American popular culture because he lampooned the American dream at the same time as he yearned for it in his movies and personified it in his own life. The Tramp character, and indeed Chaplin himself, championed an anarchic individuality and he became emblematic of the potential in America, which is the very system he criticizes so relentlessly in his work. This paradox makes Chaplin's work all the more fascinating.

Although Chaplin's film art was American, it was still strongly influenced, as were American slapstick comedies more generally, by European film-makers and comedy conventions in other countries. Chaplin himself was directly influenced by the films of French film-maker Max Linder and by English comedy conventions. In general, the silent films of America took what was vital and attractive in French, Italian, Jewish, and English comic traditions and yoked them to the enormous energy of a youthful nation and a new technology. Chaplin personified this American eclecticism and the youthful nation's search for an identity and culture. The most important work exploring in-depth America's influence on Chaplin and vice versa is Charles Maland's book *Chaplin and American Culture*.

Chaplin had a number of individual characteristics that are shared by other creative people. He was courageous, persistent, highly sensitive, and resourceful. For instance, he was courageous enough to discard movie conventions in the great humanitarian speech at the end of *The Great Dictator*. In this speech he abandons his two characters of Hynkel and the Jewish Barber to directly address his audience in his own voice to appeal for peace and empathy in international relations. Yet, he was still ironic enough to add a sting in the tail of the speech by slyly recognizing his own proselytism in this still incandescent speech on the dangers of propaganda. This does not weaken the speech, but makes it even more touching, and in the light of history, more powerful and prescient.

Creative control is a very strong theme in Chaplin's creative development. With each successive renegotiation of his studio contracts Chaplin increased his control over his creative

product. With United Artists, where he had almost complete control, Chaplin was able to take more time and reflect deeply on his work, and so the films he made with United Artists are his most complex and timeless works. However, earlier in his career Chaplin tried out new ideas which eventually came to fruition in his later mature works – for instance short films for Essanay such as *The Tramp* (1915) and *Work* (1915) show some of the basic plot-lines and gags he was to reuse later on. His need to control every aspect of film-making also extended to the performances of others. Chaplin often showed his actors exactly how he wanted them to perform.

Chaplin was always coming up with ideas for routines and feature pictures. His autobiographies provide much insight into instances of how he got specific ideas. For instance, in his autobiography he describes how as a child he once witnessed the witless panic of a sheep being chased towards a slaughterhouse at the end of the street in which he lived. Everyone found the chase amusing, as did Chaplin, but then the 'reality of the tragedy' overwhelmed him and he broke down weeping "They're going to kill it!". He credits this memory with providing the template for his future feature films: the combination of the tragic and the comic. In general he believed ideas came through his intense desire for them, which involved periods of anguish, and perseverance, so his mind became a 'watch-tower' always looking out for incidents that could excite the imagination. After generating many ideas he would then eliminate them until he had what he wanted.

Chaplin's story about the creation of the Tramp character is retold by Richard Attenborough in his film of *Chaplin* with Charlie played by Robert Downey Jr. In this story Mack Sennett tells Chaplin to put on stage makeup. Chaplin has no idea what makeup to put on, but decides everything should be a contradiction with the pants baggy, the coat tight, the hat small, and the shoes large. Costumed, the character of the Tramp magically takes shape as Chaplin senses his character and merges it with his own. This story about costume and character in the creation of the Tramp is archetypal: the merging of costume, mask, character, and actor is centrally important to the ways that actors create the theatre experience, which does indeed appear to be other-worldly, although it is underpinned by constant practice and skill mastery.

Comedy involves constant creativity. It is not loose and indiscriminate horseplay but a highly structured activity, involving, in particular, the manipulation of language (or symbols), and timing. Visual gags follow a logic of mathematical precision and actors become masters of timing, pacing, and spacing in order to create suspense and surprise and fulfill the potential of a joke. Slapstick, according to Chaplin, had a very exacting psychology that he initially found difficult to blend with The Tramp's (and his) preference for pathos and sentimentality, and his evolving complex comedies. Chaplin studied laughter seriously and he worked hard to make slapstick work in tension with pathos. Because he did not use dialogue Chaplin became a very good actor – he used his body and face to their full effect to convey his messages.

Chaplin's methods were exacting and time-consuming. He would improvise, but he paradoxically left nothing to chance. Chaplin would often start from a vague premise, for example 'Charlie enters a health spa' and he would then have sets constructed and work with his stock company to improvise

gags around them. He almost always worked his ideas out on film, a method that seems incredible now that film production is so tightly managed and controlled. This improvisational process carried on as ideas were accepted and discarded, until eventually a narrative structure would emerge. This process frequently required Chaplin to reshoot an already-completed scene that might have otherwise contradicted the story. These unique film-making techniques became known after Chaplin's death when rare surviving out-takes were discovered and then examined in a 1983 documentary, *Unknown Chaplin: My Happiest Years*.

However, there were downsides to his methods. Until he began making spoken dialogue films with *The Great Dictator* (1940), Chaplin never shot from a completed script. He once had a café set built with no idea how he was going to use it; he simply argued that 'something always happens in a café.' Consequently Chaplin took longer to complete his films than his rivals, as he would go over and over his scenes until he was satisfied. He would shoot every single rehearsal and view them on a screen several times, so that he could find the flaws which spoiled the effect he was striving for. He would start again if he was not satisfied, and he was his own harshest critic. This combination of improvisation and perfectionism often resulted in enormous expenses and it was also emotionally and physically exhausting for Chaplin.

Like other artistic people Chaplin experimented with forms and mixed genres. He used satire, parody, pathos, tragedy, and melodrama. Chaplin was the first to introduce a sad ending in his comedic films. He introduced fantasy sequences, and irony, and was innovative especially in the genre of romance. At Essanay Chaplin helped pioneer film as something more than a short reel car chase, and from that point on developed longer, more complex, and more developed stories. As well as experimenting with different artistic dramatic forms, Chaplin used fast-developing film technology to its utmost to bring his visions to screen.

Chaplin was innovative in his use of a variety of scenarios involving a vast array of props, film editing, and film-making effects, to make unique and entertaining films. Speeding up the camera and running the camera in reverse were two simple techniques often put to use. But Chaplin pioneered many other editing and special effects techniques, including set building, motion tracking, and close-ups. Animals and children were used by Chaplin to great effect in *The Kid*, and *The Circus*, two of his most admired movies. Chaplin even used titles artfully, as can be seen at the end of *City Lights*.

Chaplin could play several musical instruments, and was a composer and a dancer. He credits music with giving him many ideas for his comedies. It seems ironic that Chaplin is famous for his refusal to give in to sound until he absolutely had to while he was such a master of sound himself. Charlie's physical grace was legendary; he was balletic, athletic, and gymnastic. One of the best examples of Chaplin's skill at expressing ideas physically through dance and music can be seen in *Modern Times*. This film, a social and political satire, showed "mass production to be a form of social choreography." Chaplin both describes and criticizes the dehumanizing factory environment through comedic balletic play.

Chaplin, like many other creative people, was a risk-taker. He had a highly entrepreneurial spirit and as a young person

was continually preoccupied with business schemes. He learned resourcefulness in his childhood, and these lessons stood him in good stead as he grew up. His move to America was crucial in realizing his entrepreneurial spirit; he saw opportunity there and he wanted to make money, and lots of it. Even so, he himself credits some luck in his casting and in various key moves he made during his career.

Risk-taking is one of the outstanding features of Chaplin's personality. Chaplin made art during the apocalyptic and devastating First and Second World Wars and during this period he was an outspoken political critic of world events. Although Chaplin never consistently identified with any specific religious or political ideology he was often outspoken on some issues. He is most accurately described as a nonconformist and independent thinker.

Because Chaplin was outspoken and was the premier film star of his age, an influential figure, he became the target of persecution. It did not help Chaplin that the film industry was at the vanguard of reformulating moral codes in post-Victorian America, and his personal life was colorful and controversial. Yet, despite the high stakes of failure as a high profile public person he took risks constantly with his reputation and his fortune.

Modern Times was a bold risk for an artist of Chaplin's stature, and it did not make money until it went into foreign distribution. Chaplin chose as his first talkie movie a biting satiric critique of Hitler's rise in Europe, *The Great Dictator*, which was an enormous financial, personal and artistic gamble. Chaplin put much of his personal fortune into its production. Chaplin's comic genius and courage is shown in one particular scene of sublime ridiculousness which aims at destroying Hitler's credibility. Hynkel savagely splutters through one of his diatribes against Jews in Germanic sounding nonsense words. As he walks back to his seat after his last expletives are delivered, Chaplin delivers his final comment on Hitler's intelligence as Hynkel picks up a glass of water, and puts it in his . . . ear. In 1997, *The Great Dictator* was selected for preservation in the United States National Film Registry by the Library of Congress as being "culturally, historically or aesthetically significant."

Summary and Contribution

It is easy to underestimate the power and force of a comedic character who has become so familiar. Just as we get used to electricity or fresh water from a tap, the creation of a comedic character like Charlie's Tramp is truly revolutionary. However, with a comedy symbol such as the Tramp the power of the invention is always to some extent conditional on an audience's desire to sustain the invention. A character such as the Tramp needs to speak directly to an audience that is receptive and listening to him.

Chaplin created his character, but his audience adopted him, and then eventually largely rejected him. In the present era there has been a renewed appreciation of his work by fans, researchers and writers and others rescuing his significance from the largely undeserved damage done to his reputation in his later career. Chaplin has spawned a critical industry appraising his work, remains a relevant point of learning for actors and film-makers, and is now reborn via the Internet to a

vast new audience, who are viewing and reinventing his work again. The popular conversation about Chaplin's films on the Internet, which occurs in all languages, attests to his continued relevance as an international comedian.

Chaplin was able to straddle both the popular audience and yet, at the same time, gain artistic credibility. Because film was a relatively new medium, especially as a form of mass entertainment, he can be argued to be critical to the development of film as an art form because he showed the potential of the medium to communicate complex themes. In his mature period Chaplin made intricate films, his vision was unprecedented, and he provided an abrasive exploitation of paradox and ambiguity. He mastered the discourse of comedic language even though he initially eschewed the talkies. Chaplin was the premier comedian and film maker of his time, and remains influential in the present day. His contribution as a creative person himself and as an inspiration to countless other people has been unique, widespread and timeless.

Julia Child 1912–2004

L B Flore, Lesley University, Cambridge, MA, USA

© 2011 Elsevier Inc. All rights reserved.

Au début – In the Beginning

The oldest of three children, Julia Carolyn McWilliams was born in Pasadena, CA. During the early years of her life, Pasadena – a conservative city best known for the annual Tournament of Roses Parade – was experiencing tremendous growth in terms of population and cultural activity. Benefiting from the city's prosperity, Julia's father, John McWilliams, was a successful, conservative businessman who worked as a farm consultant and real estate investor. Mrs McWilliams, whose family fortune was made in the paper industry, managed the home front with the help of a maid and cook. Living in Pasadena, Julia grew up with a great appreciation for the bounty of fresh fruits and vegetables available, as well as the quality of meat the cooks prepared for the family's meals. Nevertheless, Julia was not inspired to try her own hand at cooking, and the family's dining experiences consistently centered on basic American dishes, such as chicken and potatoes, and an array of tasty albeit nondescript brown sauces that were common in that era.

La jeunesse Julia – The Young Julia

Julia and her siblings grew up with many comforts, enjoying a range of activities, particularly outdoor sports such as tennis and skiing. Career goals were not a part of Julia's early education experience, yet her natural leadership qualities emerged as she developed into a young woman – a rather tall woman at 6 ft, 2 in. Mr and Mrs McWilliams chose to send Julia to an elite boarding school for her high school years, deciding that it was time for her to receive a more serious education. As the tallest person in her class at San Francisco's Katherine Branson School for Girls, Julia was a standout in terms of her overall presence, including her physical stature as well as her knack for verbal candor and adventurous spirit. Although her mother's ancestry included famous intellectuals William Cullen Bryant and Oliver Wendell Holmes, Julia's intellectual abilities were not what distinguished her from her peers. It was her flair for dramatics and physical activity that made her a social success and 'head girl.' She was taller and stronger than her peers, and was a self-proclaimed ham.

In 1930 Julia's academic standing, paired with the fact that she was the daughter of an alum, was strong enough to gain her admission to Smith College, in Northampton, Massachusetts. With the same panache she had displayed in high school, Julia completed four successful years at college, and was once again the tallest woman in her class. While in college she majored in history, and blithely entertained the notion of becoming a writer or basketball player. She graduated from Smith in 1934 with her degree but not a wedding engagement, which was the ultimate goal of many young women at the time. Women's careers were somewhat limited at the time of

her graduation, and her family's financial background did not require that she take up a profession. Since Julia did not savor a career as teacher or nurse, she instead moved to New York.

In New York Julia shared an apartment with friends from Smith, and was primarily supported by her parents. She took up a brief occupation as a copywriter, working in the advertising department of the well-regarded home furnishings company W&J Sloane. She stayed in this position for a few years, refining her natural talents for writing and communication. She learned to write press releases and to work with staff photographers, as well as handle public relations under the tutelage of the advertising manager. Julia's success in this position was accompanied by personal successes submitting her own written work to magazines, such as the *Saturday Review of Literature*. She enjoyed a rather active social life in New York, and kept up a solid network of friends. Julia was known to be quite modest and to focus on the strengths in others and downplay herself in social situations. Her friends shared Julia's enthusiasm and appetite for stimulating activity, and yet Julia was not quite satisfied. She was unhappy over the end of a romantic relationship and was concerned about her mother's ailing health, so after her time in New York postgraduation, she ultimately returned home to Pasadena.

Julia's mother passed away a mere two months after her return to California. She decided to stay on the West Coast and take care of her father, and landed a job writing for a newly created fashion magazine. She later transitioned to a job overseeing the advertising office of the West Coast branch of W&J Sloane. In the early 1940s, however, she was feeling less eager to continue with her job. She was purportedly fired for insubordination – an outcome she felt was justified and that she did not regret.

Il était censé être – It Was Meant to Be

Julia believed and often said that the Second World War changed her life. As America became more entrenched in the war, Julia desired to support the war effort. Julia did not share her father's Republican political views, and was a loyal and enthusiastic democrat. She moved from California to Washington, DC and applied for positions with the WAVES (Women Accepted for Volunteer Military Service) and the WACs (Women's Army Corps). She was disqualified from a position in either service organization because of her height, but would not be deterred, and accepted a job as a typist in the Office of War Information.

After only a few months she applied for a job with the newly formed Office of Strategic Services (OSS), hoping to engage in work as a spy. Her skills at organizing material as well as leading staff worked to her advantage, and she eventually headed up an office of 40 employees, working six days a week. In 2008, thousands of pages of personnel files were

de-classified by the National Archives and it was revealed that Julia did indeed work as a spy for the OSS during the Second World War. She worked as part of a large spy network created by President Roosevelt, which was precursor to the organization known today as the Central Intelligence Agency (CIA). It was in this capacity that she was sent on an overseas assignment in 1944. She and her colleagues were stationed in Ceylon (now Sri Lanka), an island off the coast of India. Julia worked in the OSS headquarters for South East Asia, where she aided in the communication of top-secret documents between American government bureaucrats and corresponding intelligence officers. She was thrilled to be in a foreign country, working in a position that involved such urgency and energy, and introduced her to so many interesting people.

One of the most important people that she ever would meet was a man ten years her senior – Paul Cushing Child. Paul, a fellow OSS employee who worked in the map-making department, came from a well-respected Boston family. They met in 1943 through chance circumstances but their friendship quickly solidified as Julia was fascinated by Paul's worldliness – especially his artistic talents and passion for food. Paul was transferred to China, and Julia followed soon after. Paul introduced Julia to cooking while in China, where they compared their Ceylonese dining experiences with Chinese cuisine. Julia's experiences with foreign cuisine opened her palate to new possibilities, and what could have been a mere work friendship blossomed into something much more serious and transformative for her.

Julia had experienced serious romantic relationships in her life, but had never met the man whom she could call her true love – what she referred to as 'simpatico' – until Paul. It was with Paul that Julia felt an awakening of her senses as well as her intellect. When the war ended, she and Paul went their separate ways, and she returned to California and began to study fundamental cooking in Beverly Hills. She and Paul maintained their relationship, and eventually they decided to take a trip across the country together, from California to Washington, DC. They had decided to marry by this time, and their cross-country trip turned into a journey into the next chapter of their lives. Married in September 1946, they set up their home in Washington and Paul worked for the Foreign Service while Julia practiced her cooking on her new husband. They lived in Washington, DC for two years, when Paul was assigned to a post in Paris – a turn of events that would forever influence Julia's personal experience with food and transform the art of French cooking in America.

La belle France – The Beautiful France

Julia was thrilled with Paul's assignment at the American Embassy in Paris, for the city possessed the glamour and allure of a bohemian lifestyle. They settled in Paris in 1948, and their first meal upon arrival was the catalyst that launched Julia's passion for French cuisine. Paul drove them to a restaurant listed in the *Guide Michelin*, named Restaurant La Couronne, and Julia's meal of sole meunière was at the heart of the most exciting dining experience of her life. She was quite inspired by her perfect dining experience, from the manner of the servers to the kindness and knowledge of the maître d', but the food

triggered something inside of her. While Paul worked running the exhibits office for the United States Information Service (USIS), Julia began exploring the marketplaces. She spent much time attempting to converse with vendors in the markets, getting to know them and practice her French. She was so moved by the quality of available ingredients and the attention given to the simplest preparations that she endeavored to learn French, signing up for private lessons with Berlitz so that she could better converse with the neighborhood shop owners and merchants and try her own hand at French cooking.

As her passion for French cooking and culture grew, Julia decided to invest some of the inheritance she had received upon her mother's death and use benefits of the GI Bill to enroll in cooking school at Le Cordon Bleu. Once again, Julia was a standout among her peers – the only woman in a class of 12. Her classmates were eleven former GIs who seemed to approach cooking from a very trade-oriented perspective, instead of the artistic, creative angle that Julia enjoyed. She watched her professor, Chef Bugnard, with rapt attention and admiration, learning much from the enthusiasm that he brought to cooking, and the careful manner in which he approached preparing the most simple of dishes or accompaniments. Her competitive spirit buoyed her confidence as she worked hard to keep up with her fellow students, taking copious notes and practicing at home. She particularly admired qualities of a few instructors, such as Pierre Mangelatte's recipes, which were written with clarity and were easily understandable, and the amazing attention to detail of Claude Thilmont.

Her formal cooking education sparked new ideas for Julia, and she was quickly able to build upon the rough cooking foundation she had built while taking cooking classes in California. She learned to be more creative using fewer ingredients and spices, letting the natural flavors of the food take center stage. Paul became her willing partner at their home, readily eating her homework and marveling at the way she was able to move in the kitchen. In a letter to his twin brother, Charlie, he compared Julia to a symphony conductor as he admired her nimble movements.

It was around this time that Julia first learned of a new machine that was gaining popularity in the United States – the television. Through correspondence with friends and family, she learned of the concerns people had about how the effects of this new invention would forever change the American family. Though she and Paul tried to find a television in Paris, there was none to be found. Julia had no way of knowing what an impact she would have on American television and her self-confidence was not very strong after her first attempt to graduate from Le Cordon Bleu.

Julia failed her first graduation exam in 1951, but became more determined than ever to master the art of French cooking and gain her diploma. She had recently joined an exclusive dining society, Le Cercle des Gourmettes. They were interested in attracting more American members, and met in a model kitchen every other week for cooking presentations and instruction, and then ate the gourmet fare that they had helped prepare during their presentation/instruction. Julia relished these meetings, as she was able to learn much about French cooking and meet a diverse group of French women.

It was through this group of women that she met Simone Beck Fischbacher, a fellow Gourmette. Julia and Simone

connected immediately through their mutual love of food – from food selection to careful preparation to fine food establishments. Simone introduced Julia to another Gourmette, Louise Bertholle. Simone and Louise had been working for some time on a cookbook that they aspired to publish in the United States. Julia thought that a book filled with well-researched French recipes was perfect for the US market, where French food was relatively unknown.

These three culinary compatriots – Julia referred to them as her ‘French sisters’ – found such a common desire to create recipes others could learn and recreate in the comfort of their own homes that they formed a new enterprise. They formed a cooking school of their own, called *L’Ecole des Gourmettes*, and convened their first class in January of 1952. They later renamed the school *L’Ecole des Trois Gourmandes*, which Julia fondly translated as *The School of Three Hearty Eaters*. Each woman brought her own strength to the effort, and Julia had a knack for illuminating the practical matters involved in cooking the recipes that her French colleagues overlooked from their lifetimes experiencing French methods or else knew instinctively. For example, Julia painstakingly experimented with typical American ingredients as they worked to create French recipes that would work with typical American ingredients. When they planned to teach a lesson involving piecrusts, Julia discovered that there was a fundamental difference in American and French flours. A piecrust made with French flour required less fat to create a rich, delicious crust, but the flour spoiled more quickly than American flour. This scientific approach to knowing her ingredients led to innovative approaches to cooking classic French dishes with an American flair.

Julia’s comfort with experimentation was also reflected in her attitude toward mistakes. Julia believed that making mistakes was a critical part of the learning process, and that cooks should never apologize for their food or make excuses, for then they would fall into the self-deprecating behavior that would hinder, rather than benefit their learning. It was through continual trial-and-error, accompanied by evaluation of her teaching technique, that Julia discovered the specific steps needed to perfect individual items that would eventually find their way onto an eager diner’s plate.

When the freelance editor that had been helping Simone and Louise quit, leaving the two women without an accurate lens onto Americans’ cooking needs and habits, they asked Julia if she would step in and help them complete their project. Julia was thrilled with the offer. She accepted immediately, and thus began a collaboration that would combine Julia’s sense of humor, communication, research, and organization skills, and her ever-evolving passion for food into an enduring masterpiece.

La cuisine française – The French Cuisine

Julia received her diploma from *Le Cordon Bleu* in 1952, and delved intensely into her work on the cookbook, tentatively titled *French Home Cooking*. She investigated every step that her coauthors took for granted, as she recognized that American cooks would appreciate understanding the ‘why’ behind the suggested techniques. She wrote narratives to accompany the recipes, as she reasoned that American cooks would benefit

from concrete examples or anecdotes that would provide context to their dishes. Julia also intuited that some French techniques were revered, yet were never questioned and therefore were often misunderstood. She dared to investigate some of the old wives’ tales and urban legends related to certain classic recipes in an effort to provide a detailed explanation inside the technique that would result in imaginative, foolproof recipes.

An example of the forthright, investigative manner in which Julia attempted to understand elements of French dishes was when she was pondering the use of butter in French sauces. She and Paul went to a small bistro and met the chef of the bistro, who kindly invited them into her kitchen and demonstrated her method of making *beurre blanc*, a butter sauce that was a regional specialty but that no cookbook explained in comprehensive detail. Julia paid close attention to the method that the chef used to create a delicious sauce, and then went home to try her own hand at the sauce on her own stove. She used her own language to interpret the steps involved in creating the butter sauce, and ultimately served a dish to a group of friends. The outcome, she felt, was tremendous, and underscored her desire to revise all of Simone and Louise’s recipes. She wished to eliminate readers’ misunderstandings or the need for readers to make assumptions because of a lack of information or lack of clarity provided in the recipes.

The work of producing the cookbook turned into a laborious effort that included a pinch of luck and a dash of coincidence. Mr Sumner Putnam – head of the original publishing house, Ives Washburn – sent a letter to the authors, requesting their finished manuscript in a few months. Julia sent him a letter back explaining the innovative nature of their cookbook, and their logical approach to cooking complex French dishes. Julia received no response from anyone at Ives Washburn, but she had begun correspondence with Avis De Voto, a resident of Cambridge, Massachusetts. Julia had read a column in *Harper’s Magazine*, written by Avis’s husband Bernard, about the unsatisfactory quality of American-made cutlery. Julia and Avis subsequently struck up a trans-Atlantic friendship discussing cutlery, cuisine, and Julia’s cookbook. Avis had connections to Houghton Mifflin publishing company, her husband’s publishing house, and the cookbook trio finally left Ives Washburn and entered into a contract with Houghton Mifflin to deliver a cookbook that would introduce American cooks to the art of French cooking. Unfortunately, when the cookbook was finally finished in 1959, totaling over 700 pages, the editors at Houghton Mifflin balked at the length and the projected cost of production. While they respected the effort and research that had been put into the work, they felt that consumers would prefer a shorter book, and suggested they consider turning their masterpiece into a series of smaller books. Houghton Mifflin suggested that the women contact Doubleday – a large publishing house with their own book clubs. Avis De Voto, however, who had become their biggest fan and advocate, sent their manuscript to another contact at Knopf publishing house without asking Julia or her colleagues’ permission. Avis had a strong feeling that the publishers at Knopf possessed the vision that would make Julia’s cookbook a published success.

Avis’s faith and gumption proved to be the perfect ingredients for the cookbook’s rise to published work. A new editor at Knopf, Judith Jones, was hired to work with translators of French books, and immediately resonated with the vision

that Julia, Simone, and Louise had poured into their recipes. In May, 1960, Julia finally received a letter from Judith at Knopf, in which Judith expressed her excitement at the potential for the cookbook, and the publishing company's desire to produce the work and bring it to an American market.

Nouveau à la maison – Home Again

Julia's journey as cookbook coauthor had coincided with changes in Paul's career. The couple had left Paris, and subsequently traveled to Marseilles, Bonn, and Oslo as Paul was reassigned to various positions with the USIS, now called the United States Information Agency (USIA). When Paul retired in 1961, they settled into a house in Cambridge, Massachusetts, featuring a kitchen designed by the couple and equipped with an array of utensils and gadgets that are considered by millions of fans to be Julia's magical tools of her trade [Figure 1](#). Julia's cookbook, *Mastering the Art of French Cooking*, was published the same year.

In its first year, the cookbook sold over 100 000 copies, and by the end of the decade, had sold over 600 000 copies, which was remarkable for a culinary work at that time. The book set a new standard for high quality, crisp, innovative recipes. More significantly, the cookbook altered an eating culture that had revolved around prepackaged items, such as canned goods and frozen foods. Selecting and preparing fresh, simple ingredients became viewed as a healthy, joyful experience for women who had previously seen cooking as a routine chore. Julia was quickly regarded as a culinary expert, and was asked to write articles for several publications. Four months after the cookbook was introduced to the public, Julia was invited to appear on a television program called *I've Been Reading*, featured on a local Cambridge television station, WGBH. The station was the highest-funded educational television station at the time, and Julia's television interview turned out to be the

launching pad that propelled her from successful cookbook author to household name.

Professor Albert Duhamel, host of *I've Been Reading*, did not often invite culinary guests on his program. Instead of the usual brief interview slot, Julia was given a 30-minute interview, and she arrived to the set with a variety of equipment, such as a hot plate, assisted by husband Paul, now retired and unofficially managing Julia's work. During the interview, Julia enthusiastically demonstrated the proper way to make an omelet, from chopping the items that would fill the omelet to whisking the eggs with a flourish inside a big copper bowl. She was so absorbed in her cooking that she never mentioned the cookbook, but her appearance prompted many letters from viewers who raved about her and wanted to see her make more television appearances.

Combinaison parfaite – Perfect Combination

The hungry viewers' wishes were granted, as Julia was asked to film three half-hour shows that would be aired as pilots so that producers could gain a sense of viewers' responses to Julia's cooking ability and personality. Called *The French Chef*, the three programs were titled, *The French Omelet*, *Coq au Vin*, and *Soufflés*. The shows were received quite favorably, and viewers enjoyed Julia's good humor and ease in front of the camera. WGBH offered Julia the opportunity to film a series of 26 subsequent cooking episodes of *The French Chef*, which aired weekly. The program became the longest-running program in the history of public television, and Julia's knowledge and finesse was recognized with a Peabody Award in 1965 and an Emmy Award in 1966. It was Julia's boldness and flair for teaching that made her a legend.

As her teaching continued to build a broader fan base, she expanded her writing and television enterprise. Her dedication to the craft and rigor involved in cooking inspired Americans

Figure 1 Julia Child's kitchen at the Smithsonian.

to take risks and become show people in their own kitchens. Whether flipping a pancake or frosting a cake, in front of an audience or on the pages of a text, Julia's message was that food was something to be savored and trusted, not feared.

Julia's desire to find someone with whom she could be simpatico was echoed in the devotion of millions of fans, but her number one fan and supporter remained her husband Paul. In 1989 Paul suffered a stroke and was forced to relocate to a nursing home to receive the care he needed. Julia reduced her feelings of loneliness by immersing herself in new projects. She had founded COPIA: The American Center for Wine, Food, and the Arts in northern California in 1981, and she continued work that would promote an understanding of the quality and overall importance of wine and food. She began collaborating with fellow chef Jacques Pepin, who had envied and praised her work on *Mastering the Art of French Cooking*. Their relationship proved to be very satisfying, as their rapport contributed to the comfortable manner in which they chatted comfortably preparing and eating French food.

Un nouveau debut – A New Beginning

When Paul – husband, friend, and artist – passed away in 1994, Julia continued to write and work on television programming for two years. She had been inducted into the Culinary Institute of America's Hall of Fame in 1993, which elevated her to a new level as the first female inductee. She was awarded France's highest honor, the Legion d'Honneur, in 2000. In 2001 she moved to a retirement community in Montecito, California and donated her house and office to Smith College. Her kitchen, however, including utensils and a collection of 800 knives, was generously donated to the Smithsonian National Museum of American History in Washington, DC. She donated her cookbook collection to the Shlesinger Library at Harvard University. Her legendary pots and pans were brought to Washington, DC from COPIA – reunited and appreciated by a new generation of fans and followers.

Julia Child passed away a few days shy of her 92nd birthday, due to complications of kidney failure. In the year before her death she endured knee surgeries, kidney failure, and suffered a stroke. She opted not to receive treatment when her doctor informed her of an infection that would require hospitalization, remaining the conductor of her own symphony to the last.

Toujours bon appetit! – Always Bon Appetit!

Julia Child's contributions to the culinary field reflect a level of creativity that was unsurpassed by her peers. She was not born a talented chef, nor was she exposed to innovative cooking techniques and meals as a child that inspired her to pursue a career as a French chef. Rather, she possessed a predisposition toward cooking that was manifest when her temperament met with circumstances that resulted in opportunities for her talents to flourish. Throughout her career she was able to adapt cooking to the trends of the times and the needs of consumers. Several qualities stand out as particularly relevant to her creative success:

1. *Learning environment*: Julia's life path brought her to foreign countries, where she felt invigorated and met Paul, whom she credited with awakening her senses. In Paris, the environment sustained her initial appreciation for French cooking, but strengthened her developing knowledge of aesthetics and gastronomy, encouraging her to try her own hand at creating delicious, innovative food. Her travel experiences afforded her the opportunity to combine knowledge from diverse cultures, broadening her palate as well as her vision.
2. *Gift of association*: through her own methods of scientific research, Julia gained a working knowledge of the chemical properties of ingredients and the physical properties of cooking equipment, as well as their respective limitations. As this knowledge base developed, she was able to make associations between otherwise unrelated ingredients and recognize unique combinations that resulted in truly savory dishes and accompaniments.
3. *Comfort with the unknown*: the learning process, which Julia believed to be a lifelong endeavor – entailed not only testing of hypotheses but also exploring uncharted territory in the culinary world. Recognizing the ambiguity in a combination of ingredients or a process of combining the ingredients did not serve as a deterrent to her professional pursuits, but rather awakened her imagination to new possibilities, combinations, and ideas that she could work into a recipe.
4. *Acceptance of mistakes*: a natural extension of experimentation and exploration is sometimes making mistakes. Julia's ebullient approach to cooking was linked to her self-forgiveness and sense of humor. Mistakes were not viewed as failures, but necessary steps in the learning process that revealed new information that translated into opportunities for deeper understanding.
5. *Flexibility of mind and spirit*: Julia's ability to move between countries and cultures, to speak and understand different languages in different contexts, and to coordinate materials and people served her well in her cooking, writing, and television activities, and was evident in her earlier years as well. Her mental and manual dexterity proved invaluable as she worked on numerous projects throughout her career.
6. *Persistence in the face of obstacles*: The burning passion that Julia possessed for food and eating may have fueled the fire for her tireless energy creating dishes for others to enjoy. Her efforts creating *Mastering the Art of French Cooking* are but one example of the tremendous effort involved in seeing a project through from inception to completion. The delay of gratification required as she toiled in the kitchen perfecting recipes and narrative, while publishers suggested that she shorten the cookbook to something briefer and catchier is an example of an inner drive that dominated any urge to quit or settle for a less-than-ideal product.
7. *Support of family and friends*: Paul's unwavering support was a critical ingredient in Julia's success. His own creative endeavors centered on art and photography, which he used to help Julia plan illustrations for her cookbook, design her incredible kitchens, and document their life together – capturing the sights and people that served as constant visual reminders to Julia. Julia also surrounded herself with encouraging, stimulating friends and teachers. Many of these friends served as inspiration for her to follow her dreams, and others served as vital contacts that moved

her career forward at critical points throughout her lifetime. Recognizing the strengths in others, she strengthened the likelihood that she would succeed in her efforts.

Julia Child's career spanned more than 40 years as a television personality, and her writing continues to influence people today. Her respect for *la cuisine française* never faltered as she opened the door to new and wonderful opportunities for American home cooks. Inasmuch as she inspired people to enjoy cooking, she ultimately set in motion a new approach to education and communication, forever laced with her signature *joie de vivre*.

Camille Claudel 1864–1943

B Cramond, The University of Georgia, Athens, GA, USA

© 2011 Elsevier Inc. All rights reserved.

Background

Camille Claudel was a sculptor during the very artistically active Fin de Siecle, or end of the nineteenth century, in Paris. Although her work was lauded by critics and fellow artists, she had little commercial success during her life-time. The popularity of her work and interest in her life have grown in recent years. Much of the interest is due to the details of her life, which include beauty, extraordinary talent, romance, betrayal, defiance of convention, and tragedy.

This renewed interest is not just because of her talent, though she was certainly a talented artist, nor due to her beauty, though that does add appeal to her tale. The interest is not even due to her very tempestuous relationship with Rodin, though that ensured her place in history. In fact, it has been argued that her story and talent were often obscured by her relationships with the two creative men she loved: her brother, Paul, poet and statesman, and her lover, Rodin, an established sculptor at the time they met. Her story is of continued interest because it is such a tragedy and such a lesson about what can happen to someone who steps out of society's limits, in her case, the limits imposed upon young women creators.

This resurgent interest spawned an eponymous movie about her, released in 1998 starring Gerard Depardieu and Isabelle Adjani; a musical, which premiered in 2003; several recent art exhibits featuring her work, one alongside the sculptures of Rodin; the publication of several biographies about her; a novel and poem; and the establishment of at least one school named after her, the Lyceé Camille Claudel. Yet, her immortality is best ensured by her distinctive features evident in some key sculptures by Rodin and what remains of her own art.

Early Life and Family

The oldest of three children in a middle class family, little is known of Camille's early childhood, except that the family was described as bourgeois, arrogant, and quarrelsome. By all accounts, Camille's father, Louis-Prosper, was a civil servant who provided the family with a comfortable lifestyle and moved them often due to position reassignments. He had a volatile temper, but favored Camille and supported her interests in sculpture, both emotionally and financially.

Her mother, Louise, on the other hand, neither understood Camille's disinterest in feminine pursuits nor had patience with Camille's volatile temperament. Louise paid little attention to art and much preferred her younger daughter, also named Louise, whose interests and temperament were more like her mother's. The two Louises disapproved of Camille's choices and lifestyle, and it is clear that the youngest child, Paul, was often jealous of his accomplished older sister, Camille. He wrote a preface for Camille's posthumous exhibit in 1951 in which he said, "I see her once again as she was, a superb young woman, triumphant in her beauty and genius,

wielding an often cruel ascendancy over my early years." In spite of their rivalry, Camille and Paul were very close growing up, and it has been speculated that their artistic competition, though in very different fields, inspired both to greater heights.

Other early influences on Camille's work include the countryside in which she grew up, the effects of her family's frequent moves, and her father's interest in the classics. It was said that Camille was almost preternaturally drawn to nature, and she and Paul often took long walks where she undoubtedly was impressed with large rock formations they saw. In addition, the family's frequent moves prevented Camille from making close friends outside of her family, so she had long periods of solitude. An avid reader, Camille had access to her father's library, which included a good collection of classics. She also had time to model figures out of clay, something she reportedly started at an early age.

One of the most important developments in her artistry occurred in 1876 when the family moved to Nogent-Sur-Seine. The family hired a tutor for the children, and Camille, 12 years old, continued with her nascent art, getting family members to model for her. It happened that the sculptor, Alfred Boucher, had a home near the Claudel family at this time, and he was struck by the young girl's talent. Although it is not clear how much instruction he gave her, he undoubtedly introduced Camille to some techniques, art exhibits, and eventually to other sculptors, most notably Auguste Rodin. During this time, Camille sculpted works that showed such promise that an art critic, Morhardt, later commented upon them in an article.

In 1881, Louis-Prosper established his family in a home in Paris while he continued to live in the country. There is some dispute as to why Camille's family split at this time. One theory is that Louis-Prosper wanted his growing children to receive the kind of education that they could not get in the more provincial schools. But, Paul wrote that it was Camille who forced the family to move to Paris so that she could pursue her career in sculpting. It is likely that both are true; Camille was ambitious, and Louis-Prosper wished to afford his talented children the opportunities to follow their ambitions: Camille in art, Louise in music, and Paul in writing.

Paris and Rodin

Even in Paris, Camille was not allowed to enroll in the all male and prestigious Ecole des Beaux-Arts, so she enrolled in a private art school that did admit females and rented a studio with three other female students. For the first time, Camille had the companionship of females with similar interests. One of the girls, Jessie Lipscomb, remained a friend for life.

Boucher stopped by the studio regularly to advise the young women, until he won the Grand Prix du Salon and left for Italy the next year. He asked his friend, Rodin, to visit the girls in his absence and help them. There is no record of Rodin and Claudel's meeting, and various accounts place it sometime

between 1881 and 1883. At the time, Rodin was in his 40s and Camille was between 17–19; he was 24 years her senior. He was a ground-breaking sculptor who was beginning his ascent to fame, and she was a beautiful, talented, and bright young woman. Her brother, Paul, described her as having magnificent blue eyes and hair as “red as gold.” Her beauty surely caught Rodin’s attention, as did her passion to sculpt. His talent and passion for his art must have been very attractive to her, too. That they were soon lovers has been verified by the discovery of an ardent love letter from Rodin to Camille written in the fall of 1883.

By the next year, both Camille and her friend, Jessie, were employed in Rodin’s studio where he was feverishly working on the Gates of Hell and The Burghers of Calais. As with most such studios of the time, students were required to work on the parts of the sculpture assigned to them while the entire project was overseen by and credited to the head artist. During this period, Camille became very involved in the creations, both posing for figures and doing more and more of the sculpting. Rodin much preferred modeling with clay to working with stone, and Camille showed great proficiency in the latter. So, she quickly moved from the role of student to one of an assistant. During this time, Rodin even finished and signed his own name to some of Camille’s sculptures. Although the Claudel family, and later Camille, accused Rodin of exploiting Camille in this way, it was typical of the apprenticeship practice in the nineteenth century for the master to teach the assistants in exchange for their work, and all work completed in the atelier belonged to the master. On the other hand, the master provided many opportunities for the young artists besides lessons – they had access to expensive equipment and materials, opportunities to meet other famous artists, introductions to possible buyers, and an entrée to the Salons. It was a symbiotic relationship that worked for a while for both Rodin and Camille.

By the time that Camille went to work with Rodin, they were involved in a fervent love affair, though she still lived at home with her mother and siblings for several years. Rodin lived with his long-time companion and former model, Rose Beuret, with whom he had a son just two years younger than Camille. Rodin’s continued relationship with Rose was one of the sources of conflict in the relationship between Camille and Rodin. Their art was another. The relationship between these two very passionate and strong personalities was never peaceful, and it was marked with drama, splits and reconciliations, long trips together, at least one pregnancy, and possible additional infidelities. By the time Claudel split with Rodin for good, they had been together for about ten years. Although Rodin finally married Rose Beuret very shortly before they both died, many of Camille’s and Rodin’s mutual friends believed that they only ever truly loved each other.

Camille’s Art

How much Rodin influenced Claudel’s work and vice versa is a matter of debate in the art world. However, it seems reasonable to believe that the two gifted sculptors who worked and lived so closely together for some time influenced each other’s work to some degree. However, in the end, they each had their own

unique style that represented their own backgrounds and influences. It is said that Camille never lost the classical influence that marked her work from the time of her study of the classics in childhood to the early influences of Boucher on her work. Her later pieces were very small and delicate. Rodin, on the other hand, specialized in large pieces, ones that were more forceful than lyrical.

It is clear that Camille was already a very talented and accomplished artist at the young age at which she met Rodin, and she continued to produce important pieces long after they had split. It has been said that her inability to support herself by selling her art was due to the difficulty of women to work and live independently at that time. Also, it was considered improper for a woman to model the human body, especially from a live model. The most prominent art critics of the time praised her work, but few bought it and even fewer commissioned it. She began to think that Rodin and his friends were conspiring to destroy her.

When Rodin established his museum in Paris at the Hotel Biron, he agreed to include a number of Camille’s works there. However, by that time, she was confined to a mental institution and was never to see it. The Musée Rodin has 15 pieces by Camille Claudel on permanent display.

Descent and Confinement

Split from Rodin and his world of friends, effectively estranged from her disapproving family, Camille isolated herself more and more to her home studio where she barricaded herself from the outside world. Her behavior, always volatile, became more erratic. At one point, she destroyed over 90 of her works. The nature and degree of her mental illness is not clear, but it seems that she did exhibit signs of paranoia in her view of Rodin’s conspiracy against her, and her personal care and hygiene suffered. However, there was no indication that she was ever a threat of violence to herself or anyone else. Whether crazy or eccentric, her condition was an embarrassment to her family.

The family balance, in Camille’s favor when it was the two Louises against Paul, Camille, and Louis-Prosper, was upset when a rift occurred between Paul and Camille. When Louis-Prosper died, the balance tipped against Camille. Camille was not present at her father’s funeral; it is assumed that she was not told. Just a few days later, her brother Paul arranged to have her taken from her home and confined in a mental asylum. At the time, one could have a family member committed with a medical certificate. Paul contacted a family doctor to write the certificate, and he and his mother acted quickly to sign the order of commitment. Paul watched with some distress as the terrified Camille was taken away in an ambulance, and he later confessed his conflicted feelings when he saw the poor mad creatures at the asylum who would be his sister’s house mates.

For Camille, confinement to the institution meant the loss of the two things she valued most: her freedom and her art. The loss of freedom for one who was once such an independent person had to be hard, but the crowning blow had to be the loss of her first love, sculpture. There are differing reports as to whether the doctors disallowed the sculpting as part of her therapy or she refused to sculpt as an assertion of her will

and manifestation of paranoia that they would steal her product. It is known that for the 30 years she was confined to mental hospitals, she did not sculpt. During those 30 years, there is a record of only one visit from her sister, after being prodded by Jessie Lipscomb, but her mother never did visit her.

Camille spent most of her time in the mental hospital, especially in the beginning, writing letters in her attempts to be released. The letters show that she still had her keen intellect and was capable of rational thought and sympathy. She wrote kindly and caring of her mother, though her mother repeatedly thwarted her efforts to be freed. Though her letters sometimes exhibited signs of the paranoia that caused her to fear 'Rodin's Gang,' poisoning, and other conspiracies against her, she also wrote movingly of her reflections on her life. She wrote to a friend, "I have fallen into an abyss. I live in a world so curious, so strange. Of the dream that was my life, this is the nightmare."

Camille and Paul

Camille and Paul were very close as children and their closeness continued into their teens and young adulthood. In fact, some have insinuated that their closeness was incestuous, or at least had erotic undertones. There is no evidence for this other than their observed closeness and intimacy, as well as Camille's strong expressions of love for Paul. It is reported that her dying words were of affection for Paul. Very likely, their closeness was fueled by their isolation, similar temperaments, passion for art, and distance from their mother and sister, Louise.

The family was Catholic as were most families from the region, but they were not religious. Camille decided early on that she was agnostic. It was only once the family had moved to Paris, and Paul attended a Christmas service in Notre Dame, that he became very devout with a strong belief that marked his work throughout the rest of his life. Undoubtedly, Paul's conversion created a distance between Camille and him. He blamed her for the family's religious lapse as he had blamed her for the move to Paris. It is probable that her growing talent inflamed his jealousy, and her illicit relationship with Rodin further upset him. Although there are differing reports, there is evidence that Camille became pregnant by Rodin and may have had an abortion. Some contend that she had multiple pregnancies and abortions, and that she may have given one or more infants up for adoption. It is sure that Paul with his newly inflamed Catholicism would have despised this sinful behavior.

Perhaps this rift explains Paul's eagerness to confine Camille to an asylum only a few days after their father's death, and his seeming indifference to her pleas to be allowed to come home. He believed that she was possessed and that she had to be confined to pay for the sins she had committed. In those days, many people believed that mental institutions were the appropriate places to confine individuals who were guilty of moral crimes, and women were the ones most likely to be so confined. As the male family member, Paul had total control over Camille's fate, and the laws of the time gave mental patients very few rights. Therefore, he was able to keep her confined, even though Rodin and others argued for her release, and her doctors agreed that she could go home. Even if Paul truly believed her to be mentally ill, he only wrote to her and visited her sporadically, once allowing seven years to lapse between his visits.

The conditions of Camille's confinement give further credence to the belief that the Claudel family was punishing Camille. First, there was a difference between regular commitment and sequestration. The former one might use with individuals with milder disorders, especially those that are not dangerous. Sequestration, cutting one off completely from the outside world, was usually reserved for the most dangerous and severely mad. The Claudels chose to sequester Camille, closely controlling her mail and visitors, perhaps in an attempt to squelch scandal. Second, there were levels of service for those confined, from first class to fourth. The first class patients got significantly better meals and accommodations than those in the fourth class, and their families paid considerably more for those privileges. Although there are indications that Camille may have started at one point in the first class, in later years she was in third class, although her family had enough money to give her a more comfortable existence. It was only after Paul quarreled with the Louises about the mother's sale of the family home to one of the younger Louise's sons, that Paul realized he had unfairly abandoned his older sister and offered to pay for her movement to first class. Paul was a diplomat and successful author who traveled around the world and had a very large chateau for his family home. He could well afford to pay all of his sister's expenses, but by the time he offered to move her to first class she refused, used to her life and reluctant to change.

Influences on Camille's Creativity

In order to examine the influences on Camille Claudel's creativity, the themes elucidated by Sally Reis in the entry, 'Women and Creativity,' in the first edition of the *Encyclopedia of Creativity* will be used as a template.

Theme One: Personality Characteristics of Creative Women and Internal Barriers to Creativity

Reis explained that introspective analyses indicated that creative women had "the ability to overcome challenges, the need for or absence of support, the opportunity to learn independently in the absence of formal education, and the willingness to live a different life from their peers or counterparts." Camille certainly overcame many challenges in seeking to become a sculptor in nineteenth century France. Women were neither allowed to enroll in art schools, nor allowed to use real nude models for their sculpting studies. Camille, a country girl, found a way to attend a private art school in Paris and employed a male model, in defiance of cultural norms. She certainly did not have the support of her mother or sister, but found support in her father. She learned independently by reading the classics in her father's library, modeling from nature and her family, and learning from the tutelage of Boucher and Rodin. She certainly lived a different life from most other girls in France at the time, and she even differed from her good friend, Jessie Lipscomb, who married and had children. Camille chose her art over the domesticity that was expected of the women of her time.

Reis went on to cite the research of Walberg and his associates that "as girls, notable women were intelligent, hard

working, imaginative, and strong-willed." All of these descriptors certainly applied to the young Camille, especially the last. She was considered to be imperious in her influence over her family, and even dared to stand up to the older and more famous Rodin.

Thus, Camille Claudel certainly possessed the characteristics typical of creative females; she enjoyed the success and suffered the consequences of their manifestations in her time. Her independence and iconoclastic nature allowed her to challenge the mores of her time, but they also isolated her from others of her gender and resulted in disdain.

Theme Two: Societal Factors that Facilitated or Impeded the Development of Women's Creativity and Why There Are so few Eminent Female Creators

That girls were not offered the same educational opportunities as boys in Camille's world is clear. She was very fortunate that her father did not have such narrow gender stereotypes as her mother, and that he encouraged her education and art. However, another major societal factor that impedes many women is the time and commitment to child bearing and rearing. In this sense, Camille seems to have made a Faustian bargain; she gave up her children, through abortions or adoptions, for her art.

The beneficial societal factors include her family's relatively comfortable lifestyle that afforded her the time and opportunity to begin to sculpt, and the opportunities to be mentored by both Boucher and Rodin. Even her family's frequent moves may have been beneficial in affording Camille the comfort of solitude, experiences with nature, and independence from peer pressures.

Theme Three: Gender Differences in Creativity and the Creative Process

Camille wanted to compete with men and sought recognition in a male dominated field. Although the content and style of her art were influenced by her femininity, she attempted to work and live as the male artists did. However, her art was not judged at the time as a male artist's work would be judged. People were scandalized by her bold, overtly sensual depictions of the human body, and her lifestyle as a single woman with a married lover was appalling. Her later works, small and detailed, were not like the bold and grand sculptures of Rodin.

Theme Four: New Initiatives or Research on Issues Relating to Women and Creativity

This theme suggests that women often manifest their creativity in more diverse and diffused ways, whereas men tend to be more single-minded. If this is so, Camille certainly expressed a more masculine type of creativity. She was very focused and driven in her sculpting from an early age, and she became more focused as she matured.

It should not be surprising that Camille expressed a more masculine focus in her creativity. She clearly identified more closely with her father than her mother. Louis-Prosper was intelligent, well-read, sophisticated, and interested in classics and the arts, everything that Camille's mother was not.

Theme Five: Internal and External Barriers to Creative Work in Women

In the years preceding and since Camille's death, much had been made of Rodin's exploitation of her and her family's mistreatment of her. The facts about these situations indicate that all parties had a part in both facilitating and hindering her creativity. But, Camille, herself would have to claim some of the credit and blame for her success and downfall. Her stubbornness and determination fortified her to pursue a career in a very masculine field in the nineteenth century. Yet, these same characteristics estranged people and further isolated her from society. Her behavior before her institutionalization seems by all accounts to have been bizarre and worsening, and she clearly exhibited signs of paranoia. So, her family did not institutionalize a perfectly normal person; though her sequestration seems to have been an extreme reaction.

Yet, Camille did not seem to be held back by many of the other personal barriers that can hinder creative women. Although she clearly had high standards for her work, she was not such a perfectionist that she was unable to complete work. She was a prolific sculptor; so few of her pieces can be found because she did not have the prestige to ensure their preservation and she destroyed so many of them herself in fits of pique.

Nor was she held back by the difference between her ambition and the facts of reality. She defied reality. She did not try to minimize the differences between herself and other women; she did not seem to have a need to be accepted by other women. Her friendship with Jessie Lipscomb was established and maintained because of their similar interests and ambitions; Camille did not change to be more popular with other young women.

She certainly did not subjugate her creative talents, at least not for long. Although she did work under Rodin for a time, her refusal to accept his style and live in his shadow was one of the major sources of contention in their relationship.

Although Camille may have suffered from periodic self-doubt, self-criticism and comparisons to others, her life was marked more by her belief in her talent, feelings of superiority to others, and disdain for those less dedicated to art. This confidence and self-esteem was characteristic of her family, and Camille seems to have gotten a strong dose of both. There is no evidence that she ever doubted her talent; she blamed her failures on Rodin. As her situation worsened, she blamed Rodin's friends as well as part of the conspiracy.

One area Camille may have had in common with other creative females is the loneliness and absence of support by other women. She had few friends as a young girl, and even Jessie Lipscomb, her only true, close female friend as an adult, was distanced from Camille when Jessie chose to marry, have children, and return to her home in England. Her last years living alone were marked by extreme solitude and isolation, then, she was sequestered in the mental institution for 30 years with very few visits from family or friends. Even in the institution, Camille kept to herself away from the other patients.

Finally, Camille certainly shared the satisfaction of the act of creation with other creative women. A study by Kirschenbaum and Reis found that female artists, especially sculptors, enjoyed the physical work of the creative process. One could

not work as long and hard as Camille did without deriving satisfaction from the work. Her satisfaction did not come from wide public acclaim or sales of her work. It probably did not even come from enjoyment of the finished product; she destroyed so many of her sculptures. Yet, she continued to work constantly, as if driven, without any other apparent source of entertainment or companionship, except for her cats. Surely she gained satisfaction from the work.

Mystery and Gamble

In the end, a good part of the interest in Camille Claudel's story is the mystery that still surrounds so much of her life. Of the many letters she wrote, very few remain. Many were destroyed by her family, and others were destroyed by individuals wishing to protect Rodin's legacy. There are continuing questions and speculation about her relationship with Paul. Differing accounts about Camille's pregnancies and whether there were living children who were put up for adoption have left lingering questions. Many of Camille's sculptures, which were not destroyed by her, have disappeared.

Whether Camille Claudel would have developed into as gifted an artist in another time or place is unknown. Whether she would have had a successful career if she had been more conforming, or more sociable, or less defiant, could only be conjectured. Was her meeting with Rodin fortuitous or disastrous? If she had been less beautiful would she have been more accepted? Camille Claudel's talent was surely the result of a number of coincidences of talent, circumstances, time, and events, as well as her actions and those of others. She gambled on living like a man and pursuing her art single-mindedly, and

she wound up paying a high price for it. It is not clear that she really had much of a choice.

Climate for Creativity

T L Friedrich, C K Stenmark and M D Mumford, The University of Oklahoma, Norman, OK, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Autonomy The perception that one has independence in decision making and goal setting with regard to the accomplishment of work tasks.

Climate The perceptions of environmental conditions that shape individuals' beliefs about the work environment.

Dispositions Underlying psychological processes that, in terms of creative climate, contribute to perceptions of support for creativity.

Participative safety The perception by team members that there is no interpersonal threat for contributing ideas.

Vision A clear, achievable mission that aligns team members toward a goal.

Introduction

It is clear that creativity and innovation are critical to the long-term survival of most modern organizations. However, creativity, or the generation of ideas that are both novel and useful, and innovation, or the implementation of those ideas, are complex and multilevel phenomena. There is a multitude of factors that influence the creative process at the individual, group, and organizational levels, some of which are complex phenomena unto themselves. Climate is one such influence. As Denison pointed out in his 1996 *Academy of Management Review* article about organizational climate and culture, climate is defined generally as the perceptions of environmental conditions that shape individuals' beliefs about the work environment. For instance, this may include perceptions of outcomes, expected behaviors, interpersonal interactions, requirements, and contingencies. Relative to organizational culture, which is a set of organizational values that influence individuals' behaviors, climate is more localized, dynamic, and domain specific. In this article we will review the aspects of a team or organization's climate that may influence creativity, outcomes of a creative climate, potential moderating factors, and ways to assess and develop a creative climate.

Given the cognitive nature of the creative process, it is easy to see that an individual's perceptions of environmental conditions relevant to the creative work will play a role in how the creative process proceeds. For instance, in their 2002 *Harvard Business Review* article 'Creativity under the gun,' Amabile, Hadley and Kramer discuss the negative impact that perceptions of time pressure have on the creative process. Additionally, in another 1998 *Harvard Business Review* article entitled 'How to kill creativity,' Amabile mentions that rewarding individuals for creativity may interfere with their intrinsic motivation and shift their focus to the reward, which decreases their creativity. Given that engaging in the creative process is incredibly cognitively demanding, perceptions of work pressure or being overly concerned about rewards contingent on creative production may overwhelm individuals and make it difficult to devote the cognitive resources needed to solving the creative problem. In this instance, work pressure and contingent rewards are examples of environmental elements that would create a poor climate for creativity.

In their 2007 *Creativity Research Journal* meta-analysis on climate for creativity, Hunter, Bedell, and Mumford demonstrate that evaluating the components of a creative climate is an important endeavor for three main reasons; creative individuals and their creative process are particularly influenced by the conditions of their work environment, climate variables are effective predictors of creativity, and climate measures provide information for specific steps organizations may take to improve creativity. Given the importance of understanding the components of a creative climate, creativity scholars have taken a variety of approaches to interpreting the dimensions, antecedents and outcomes of a climate conducive to creativity. We turn now to a review of these approaches.

Frameworks and Dimensions of Creative Climate

Motivation

Although commonly thought to be a 'light bulb' moment, developing creative ideas is actually a quite difficult and involved process. For this reason, motivation plays a particularly important role in whether individuals are likely to engage in creative problem-solving and their capacity to be successful. In this vein, Amabile, Conti, Coon, Lazenby, and Heron reviewed the development and validation of their measure of organizational factors influencing motivation and creativity in a 1996 *Academy of Management* article entitled 'Assessing the work environment for creativity.' These researchers approached evaluating climate for creativity with regard to the influence aspects of the work environment have on individuals' motivation to engage in the creative process. They identified five general dimensions of the work environment that may facilitate or inhibit individuals' and teams' engaging in creative problem-solving. These dimensions include: (1) encouragement for creativity (organizational encouragement, supervisor encouragement, work group support), (2) autonomy or freedom, (3) resources, (4) pressures (challenging work, workload pressure), and (5) organizational impediments. In general, these dimensions indicate that being encouraged, having control, and being presented with challenging yet personally fulfilling projects will positively influence an individual's motivation to engage in a creative problem-solving endeavor.

Specifically, to engage in the challenge of creative projects, studies indicate that individuals and teams must perceive that the organization is supportive of them spending time on the effort, it is acceptable to take risks, and that creative ideas are valued in the organization. Supervisor support is also critical in that leaders should provide clear, yet not overly restrictive, goals, should give fair and constructive evaluations of creative ideas, and should be willing to reward creativity, particularly with rewards that will not impede intrinsic motivation, such as recognition. For instance, a 1996 study conducted by Oldham and Cummings demonstrated that employees were most creative when they were engaged by challenging tasks, and were supported by their supervisors while not being overly restricted by them. The final element of encouragement involves support at the level of the work team. An individual working on a creative problem can perceive encouragement from his or her work team through a willingness to exchange ideas, sharing a goal to solve the creative problem, and willingness to provide fair and useful evaluations of generated ideas.

Additionally, research indicates that individuals are better able and more inclined to be creative when given autonomy in how to interpret and develop creative problem-solutions. As Amabile notes in her aforementioned 1998 article, not only does autonomy reduce the limitations of how they might go about solving the problem and thus increases the potential for a creative solution, but it also increases the individual's sense of ownership in the process. Perceptions of creative freedom and personal ownership have a positive impact on intrinsic motivation. In addition to autonomy, creative individuals also thrive when challenged. However, if the challenge and work pressure becomes too great, it may impede individuals' ability to focus on the creative problem or will draw cognitive resources away from the resource intensive creative process. Along with cognitive resources, individuals, and project teams must perceive that they have the necessary physical resources that are required. Not only does knowing that adequate resources have been provided ease the cognitive burden of finding them, it also serves as an indicator that the project is valued which has direct implications for an individual's willingness to engage in the project.

On a related note, the final climate dimension suggested to influence motivation is organizational impediments. Often there are conditions affecting the entire organization that may have an impact on individuals' and teams' perceptions that creative problem-solving is possible and valued. These conditions may include turbulence in the market, an overly rigid structure, financial insecurity, or internal conflicts. For instance, individuals in a research and development team for a struggling organization may perceive that engaging in innovation would be fruitless because the organization will ultimately not be able to implement the ideas, thus creating a poor climate for creativity. Based on relevant research, Amabile and colleagues noted this relationship and included it in the development of their previously mentioned measure of organizational climate for creativity.

Team Interactions

While some creativity researchers focused on how perceived characteristics of the group and organization create a climate

for creativity based on their impact on individuals' motivation, West and his colleagues have taken a second approach to evaluating creative climate that has focused on how team-level interactions create a climate for creativity. In their 1998 article describing the development and validation of a measure of team climate for innovation, Anderson and West indicate that members must interact regularly, that there should be an overall goal that focuses their efforts in collective action, and that their tasks are interdependent such that they have come to develop a shared understanding of how the group operates and the ways in which other members work. The specific elements of the team climate that are proposed to be relevant to creativity are (1) vision, (2) participative safety, (3) task orientation, and (4) support for innovation.

A group's vision is important to creativity because it both aligns the members of the group toward a specific goal, and is also motivating by providing focus and direction. In order for the vision to be useful, however, it should be clear, achievable, and agreed upon by all members of the team. Creative tasks are challenging unto themselves, but in a group setting, with multiple individuals working through the creative thought process individually, it becomes exponentially more complex. Along these lines, Pearce and Ensley's 2004 study on shared vision in innovation teams demonstrated that a group's shared vision of a goal was positively related to ratings of innovativeness. Thus, for individuals and groups to succeed, it is necessary that the individuals within the team share a common understanding of what is to be achieved. In addition, the goal must be clear to facilitate coordination of multiple individual efforts, and should also be achievable so that members stay motivated.

In addition to having a shared understanding of the goal, another important aspect of the team's climate for creativity is participative safety, or the perception by members that there is no interpersonal threat for contributing. Edmondson and Mogelof discuss the concept of psychological safety in a chapter in Thompson and Choi's 2006 book entitled *Creativity and Innovation in Organizational Teams*, and indicate that individuals are more likely to contribute ideas or engage in necessary critiquing of others' ideas if it is understood that they will not be judged for doing so. Not only does this result in more ideas being proposed, and a more thorough review of those ideas that are proposed, but it also increases engagement in the outcome of the creative process when the team members participate more in the development.

A third element of team interactions that promotes a climate for creativity is a general orientation of the team towards improving the team's performance on the given task. In this regard, team members are collectively committed to excellence by holding one another accountable, implementing a system for monitoring progress and establishing performance criteria, providing feedback and advice to one another, and maintaining an openness to adopting changes to improve the project outcome. In the dynamic interpersonal environments that are present within teams, it is critical to a creative effort that the focus on the task is maintained and the team be united in a desire to seek the best possible outcome. In his 2002 *Applied Psychology: An International Review* article on characteristics of work teams that promote creativity and innovation, West highlights many of these and other related factors as important for innovation success.

The final element of team interactions relevant to creative climate is support for innovation. Support for innovation can take many formal and informal forms. Formally, the team, or organization more broadly, may clearly articulate expectations and support for innovation through mission statements, job descriptions, reward systems, among others. It is also critical to individual's perceptions of team and organizational support that resources be made available. Specifically, if individuals do not feel that they have the time, technology, or financial support that they need to develop new ideas, they will be less likely to participate in innovative efforts. Informally, members of the team and organization may also create norms that indicate a general appreciation for creativity and innovation. Each of these four team processes, vision, participative safety, task orientation, and support for innovation, plays an important role in creating a team climate that will foster creativity.

Dispositional Factors

The third main approach to evaluating climate for creativity takes into consideration the dispositions, or underlying psychological processes, that contribute to perceptions of support for creativity. Ekvall, in his 1996 article entitled 'Organizational climate for creativity and innovation,' focused on individual psychological factors that may influence these perceptions and identified nine different individual dispositions. Specifically, these are personal psychological factors that are influencing an individual's willingness to act creatively. They include challenge, freedom, idea support, trust/openness, dynamism/liveliness, playfulness/humor, debates, conflicts, risk taking, and idea time.

Similar to the motivational approach, the first two dispositional factors are challenge and freedom. Under challenging conditions, individuals are stimulated, engaged and obtain meaning from doing their work and are thus more likely to put forth additional effort and engage in creativity and innovation. If individuals are distancing themselves from their work or are disengaged because of apathy or lack of a challenge they are less likely to go the extra mile to be innovative. A 2000 study by Andriopoulos and Lowe published in *Management Decision* demonstrated that organizations could promote innovation by continually challenging employees to keep them engaged. Additionally, as mentioned earlier, individuals are more likely to be creative when their behavior is not overly restricted and they are given the freedom and autonomy to find new ways to accomplish their tasks. Individuals become active participants in the work, take ownership of it and are more likely to think of better, alternative ways to accomplish their goals.

The next two dispositional factors overlap somewhat with the team interaction conditions mentioned earlier. Idea support and trust/openness are both critical to ensuring that individuals within the team and organization feel comfortable being creative. Idea support refers to the understanding that it is acceptable to question the status quo and that presenting new ideas is valued and encouraged. Trust or openness is, as mentioned before, paramount to creative climate because individuals should not worry about their contributions being ridiculed, nor should they be concerned about judgment should the new ideas fail. In a 1976 *Journal of Applied Psychology* study, Klimoski and Karol evaluated the relationship between perceived interpersonal trust and creativity and found that more

ideas were generated when individuals perceived higher levels of trust in the group. Both of these conditions create a climate that encourages individuals to voice new ideas and does not break them down for doing so.

Two other dispositional conditions within the team environment that effect creativity are the degree to which it is dynamic, engaging and lively, and the level of playfulness or humor. In a team in which these conditions are present, individuals are stimulated because they must react to a rapidly changing environment and also because the sense of playfulness releases the psychological restrictions of an overly rigid environment. It is proposed that an environment that is designed to be stable, caters to the status quo and is void of humor and levity will hinder the flow of new ideas.

Along those lines, it must also be acceptable within the group and organization to challenge the status quo and each other through constructive debate. Everyone should be given room to have an opinion. However, care must be taken to ensure that fostering debate does not lead to unnecessary and unconstructive conflict. The emotional and psychological turmoil caused by interpersonal conflict within the group can sap valuable cognitive resources and would likely lead to disengagement and a decrease in psychological safety, making it increasingly unlikely that new ideas would be shared. Chen's study on the benefits and detriments of conflict during creative projects, published in 2006 in *Creativity and Innovation Management*, supported the proposition that conflict related to the task or solving the problem can be beneficial but interpersonal conflict is likely to be detrimental to team processes.

Finally, groups and organizations that avoid uncertainty and risk will not be open to innovations. Organizations and groups must be able to respond rapidly to opportunities that call for innovation and thus must be able to accept the risk of responding quickly. All innovations are departures from the norm and thus are, in some way, risky. In addition to being allotted room to take risks, individuals must also be given the time to be creative. Innovation does not happen in an instant, so the organization and team must ensure that individuals are afforded the room to spend time considering alternative ideas. Although there has been substantial overlap in general concepts between the three approaches reviewed so far, they are not entirely comprehensive unto themselves.

An Integrated Framework

There are several other ways that researchers have gone about describing climate for creativity. In addition to the three approaches already discussed, others have focused on organizational learning, appraising the environment, employee engagement, and specific requirements for developing new products. More recently, there has been an effort to integrate the various ways that researchers have described climate factors. In a 2005 article entitled 'Dimensions of creative climate: A general taxonomy,' Hunter, Bedell, and Mumford reviewed available creative climate taxonomies and determined that nearly all of the variables included in the range of approaches could be encompassed within 14 dimensions. These dimensions include: (1) having a positive peer group, (2) having positive relationships with supervisors, (3) available resources, (4) challenging work, (5) having a clear mission or vision,

(6) being given freedom or autonomy over one's work, (7) positive exchanges with other members, (8) being intellectually stimulated by the work and those around you, (9) receiving support from top management, (10) being rewarded, (11) acceptance of risk taking and flexibility in thinking, (12) a focus on products, (13) encouragement of participation, and (14) integration of organizational processes.

This final collection of factors seems most useful because it incorporates both interpersonal elements (e.g., positive peer group, positive supervisor relationships), and task elements (e.g., challenging work, clear goals) but is also multilevel. It demonstrates that developing a climate for creativity involves individual level processes (e.g., freedom or autonomy), group level processes (e.g., positive peer group), and organizational level processes (e.g., top management support). Having reviewed the dominant ways in which the literature has defined the components of a creative climate, we now turn to the critical outcomes of a climate for creativity.

Outcomes of Climate for Creativity

Research on climate for creativity has made it clear that climate does, in fact, have a significant influence on critical creative outcomes. Additionally, these outcomes span all levels of the organization, from the individual to the organization as a whole, and also generalize across types of organizations, cultures, and focus of the work. When teams and organizations take care to establish a climate that facilitates creativity, it has been shown to have significant effects on the creative problem-solving of individuals, project adoption, project success, as well as long-term organizational outcomes.

Much of the climate elements reviewed in the previous sections are focused on the conditions that will encourage individuals to engage in creative problem-solving and help them succeed should they do so. For instance, having challenging work, autonomy and a clear goal to work towards is likely to jump-start creativity. Trust, openness and constructive criticism will keep the creative process moving forward in a positive direction. Finally, having support from team members and supervisors, and the resources required to carry it out will fuel the individual's creative process.

Another significant, and less obvious, outcome of establishing a climate for creativity is the increased chance that a creative project will be adopted. There are several components of the creative climate taxonomy that are specifically relevant, including top management support, flexibility in risk taking, and organizational support for innovation. If it is clear through organizational documents, norms, and discussion that innovation is of value, members of the organization will be more likely to buy-in to supporting the innovation – a critical point due to the level of organizational disruption that innovation often causes. The organizational support is particularly effective if it is communicated by the top management team. Additionally, if the organization is not risk-averse, it will be more receptive to implementing new initiatives.

Along similar lines, not only does a climate that supports creativity facilitate project adoption, it is also likely to increase the chances of project success. If the climate is such that all individuals feel comfortable contributing their ideas, it increases

the chances that a high quality idea will be presented. Additionally, a psychologically safe environment that encourages constructive conflict will increase the evaluation and adjustment of project ideas, resulting in more refined and higher quality solutions. In a study along these lines, Baer and Frese's 2003 *Journal of Organizational Behavior* article on climates for initiative and psychological safety demonstrated the link between critical climate variables, innovation in the organization, and ultimate firm performance.

Finally, by improving creativity and innovation, establishing a climate supportive of creativity will lead to long-term organizational outcomes such as competitive advantage, and survival. The critical role that innovation plays in the overall success of organizations has been regularly documented by organizational research and it is particularly critical in the current dynamic, technology-driven marketplace. Any organizational strategy that improves creative problem-solving and facilitates project adoption and success is a worthwhile intervention. However, while the organization or group may facilitate creativity by developing a climate that supports it, there are several intervening variables that may moderate the relationship between a creative climate and team and organizational outcomes.

Moderators

Based on prior research, it is evident that there is a variety of work, group, organization and environmental variables that may moderate the relationship between creativity and the outcomes discussed in the previous section. Specifically, the effect that climate has on creative outcomes may vary as a function of task conditions, characteristics of the group, characteristics of the organization, or the environment in which the organization is operating. It is critical to understand these moderating variables so as to implement climate characteristics appropriately based on the given situation.

With regard to work task conditions, research indicates that stage of the innovation process plays a role in how great of an impact climate has. For instance, a study published in *Small Group Research* in 2001 by Bain, Mann, and Pirola-Merlo indicates that climate has a stronger effect during research tasks than it does during development tasks and is more critical during the early stages of creative efforts rather than the later implementation stages. Additionally, other research indicates that task complexity or difficulty, and the autonomy that individuals are given may moderate the relationship as well. Specifically, the criticality of the climate variables may have a decreased impact for simpler innovations where engagement is not as critical, or for tasks in which individuals have little control over their work and thus can engage in little innovation regardless of the climate.

Along with characteristics of the work being done, there may also be characteristics of the work group that moderate the relationship between climate and creativity. The findings of a 2001 *European Journal of Work and Organizational Psychology* study by Curral, Forrester, Dawson, and West supports this in that they found that larger groups had weaker team processes as measured by climate indices. Thus, in larger groups it may be more difficult to have a clear and strong climate that would influence individuals to be creative. Additionally, varying

levels of cohesion, coordination and interdependence may impact the relationship between climate and creativity. For instance, in a group with low cohesion or coordination, it may make little difference that team members feel safe contributing ideas because the ideas will not be well integrated with the ideas of other members.

In addition to work and group characteristics, there are also organizational characteristics that may have intervening effects in the climate and creativity relationship. Although a team's climate may facilitate creativity, conditions within the organization may make it more or less likely that the product of the team's creativity can be capitalized on. For instance, Nystrom, Ramamurthy and Wilson's 2002 *Journal of Engineering and Technology Management* study on technological innovations indicated that an organization that is larger or has more available resources will be better equipped to support project ideas than a smaller firm could. In addition to size and resources, an organization's learning orientation, structure and level of professionalization can also play a role. A positive learning orientation will make the organization more receptive to new ideas, horizontal and vertical structures may be differentially appropriate given the type and scope of an innovation, and encouragement of participation may play a bigger role in a highly professional organization where members have the capability to contribute to the creative process.

Environmental factors that are external to the organization may also moderate the climate-creativity relationship. Some potential environmental moderators include turbulence, market demands, and competitive pressure. For instance, if the environment that the organization exists within is rapidly changing with ever-changing demands from customers or pressure from competitors to adapt, it is likely that enhancing a creative climate will be more critical than for an organization in a stable environment in which it is not critical that the organization develop new products or processes to satisfy customers or keep up with competitors. A meta-analysis conducted by Damanpour in 1996 supports the proposition that the environment that the organization is in plays a role such that environmental uncertainty moderated the relationship between organizational variables related to climate (i.e., structural complexity, size) and innovation.

At this point it is clear that climate is a multi-faceted phenomenon that plays an integral role in organizational creativity and innovation, but that the influence of climate may vary depending on work, group, organizational and environmental factors. To determine what the effect is, exactly, it is necessary to evaluate the presence and effectiveness of the climate dimensions. Assessment of climate dimensions also proves important if we hope to ultimately intervene in organizational processes to create a climate that supports creative efforts.

Assessment and Interventions

There are a number of ways in which climate for creativity is assessed within organizations including standardized, validated measures and localized measures used for specific organizations. On the whole, it is clear that climate can be measured; however, it is also apparent that standardized instruments, such as the KEYS: Assessing climate for creativity,

Creative Climate Questionnaire, Situational Outlook Questionnaire, Team Climate Inventory, and the Siegel Scale of Support for Innovation, are the most reliable ways to evaluate creative climate. A recent *Creativity Research Journal* meta-analysis conducted by Hunter, Bedell, and Mumford in 2007 compared the relationship between these measures, localized measures and creative outcomes and found that the standardized measures produced stronger effects sizes in their measurement of creative climate than did locally developed measures. It was thus recommended that standardized instruments be utilized when evaluating climate for creativity.

In discussing the evaluation of creative climate it is also critical to understand the measurement of the outcomes by which the influence of climate is assessed as the differences between the criteria may play a critical role in the overall evaluation of the interventions. At the individual level, creative problem-solving is often evaluated via self or supervisor ratings of creative output. Clearly both of these methods are prone to biases and, whenever possible, should be utilized in conjunction with objective measures of creativity, or at the very least be made with clearly benchmarked rating scales. A more objective criterion measure would be expert assessments of products produced (e.g., professional reviews, publication). At the organizational level, some of the criteria used to assess the contribution of climate to creativity have included innovation adoption rates, return on investment, organizational profits, and market share, among others. When evaluating the relationship between climate interventions and creative performance, it is critical that the criteria be taken into account and ideally selected to be appropriate to the climate element being focused on.

Following an evaluation of a team or organization's creative climate, it may be necessary to improve the climate or to intervene to create a climate for creativity in the first place. Given the multifaceted nature of climate, it may only involve an intervention for one element of the climate (e.g., resource availability) or one level of influence (e.g., the leader). Based on the available research and the dimensions of climate reviewed in the first part of the chapter, recommendations can be made for interventions at the leader, group process, and organizational level.

For a leader of creative efforts, the research on elements of creative climate indicates that he or she should demonstrate support for the creative effort and innovation in general and demonstrate that taking risks and shifting the status quo is something that is desired. Interpersonally, the leader should establish a positive relationship with the subordinates, and engage in a positive interpersonal exchange. In terms of the tasks being accomplished and the structure of the work, the leader should establish a clear goal, but also give individuals the autonomy and freedom to develop unique ways of achieving the goal. The work should be challenging to keep them engaged but also achievable so as to maintain motivation. Finally, if the leader is rewarding creativity, it should be rewards focused on recognition rather than concrete benefits (e.g., bonus) and somewhat distanced from the immediate creative output so that intrinsic motivation is not diminished.

Project teams, themselves, must also take steps to create and maintain a climate supportive of creativity. Although the leader may initiate certain processes, the group members should also seek to establish positive relationships with one another, create

a psychologically safe environment, and encourage participation among team members. Given that much of the creative work in organizations is conducted in teams, it is critical that team processes not interfere with individual creative problem solving, or discourage individuals from engaging in the creative process. Members must perceive that their ideas will be heard without unnecessary ridicule from other members, but should also understand that feedback and constructive criticism should be accepted without any perceived threat.

Finally, the organization as a whole may take steps to improve the creative climate. Senior leaders within the organization can demonstrate support for creativity and appropriate levels of risk taking by discussing it, modeling it and infusing it into the culture of the organization. The organization can be structured such that work flow and management structures allow for autonomy and freedom. Additionally, the organization must provide the necessary time, technology, and human resources necessary to engage in creative efforts. These organizational interventions will give individuals the perception that creativity and innovation are valued, supported, and that they will have what they need to be innovative. As we mentioned earlier in the article, climate is a function of individuals' perceptions of environmental characteristics that play a role in how they behave. Thus, these interventions that the leader, team and organization engage in are only influential if they are perceived as legitimate and genuine.

Conclusions

There are several important conclusions that should be drawn with regard to the influence of climate on creativity. First, it should be noted that climate is a complex phenomenon with multilevel factors playing a role. It can be evaluated through multiple lenses, such as motivation, team processes, or individual dispositions. Additionally, not only does research consistently indicate that climate plays a role in the encouragement, facilitation and success of creative efforts, but it is also an

organizational process that can be manipulated relatively easily to foster innovation. There are, however, moderating factors with regard to the work task, and group, organization and environmental characteristics that should be taken into consideration when determining the potential impact of climate interventions. Finally, it is clear that the elements of climate can be successfully measured and that organizations can use these evaluations to intervene in establishing a climate that will foster creativity and innovation – a worthwhile endeavor in the current dynamic and technology-driven market.

Glossary

Cognition The process of perceiving, recording, storing, organizing, and using information.

Cognitive ability Efficiency in the processing and storage of information.

Cognitive strategies Systematic methods people use to process information and solve problems.

Cognitive style Consistent individual differences in the ways people experience, perceive, organize, and process information.

Mediator A given variable may be said to function as a mediator to the extent that it accounts for the

relation between an explanatory variable and a dependent variable.

Moderator A moderator is a human characteristic variable that affects the direction and/or strength of the relation between an explanatory predictor variable and a dependent variable.

Personality trait Consistent individual differences in dispositions for specific classes of behaviors.

Validity Correspondence between what test scores purport to measure and what they actually measure.

The Construct of Cognitive Style and Its Validity

Cognition embraces a wide scope of human information processing, which includes perception, memory, language, learning, thinking, problem solving, and creativity. Over the years researchers have identified many kinds of individual differences in several such aspects of information processing, and some of these dimensions have been construed as dimensions of cognitive style. Researchers have found it useful to make further distinctions within the construct of cognitive style, such as thinking, learning and intellectual styles. Clinical, differential and social psychologists have also used style concepts like coping styles, defensive styles, expressive styles and response styles. Recently, arguments have been made to the effect that cognitive styles and learning styles should be classified under the more general umbrella of intellectual styles. In this article we will primarily focus on the more classic conceptualization of cognitive style and subsequently its relationship to creativity. We recognize the fact that both concepts that are the topic of this entry are difficult to operationally and reliably measure, which makes the discussion of their relationship all the more problematic.

The term 'style' designates a preferred manner or way of doing things. Hence, cognitive style can be defined as consistent individual differences in the ways people organize, and process information. A number of style theories exist and operational definitions of cognitive style have focused on a person's typical mode of cognition as reflected in, for example, his or her main dispositions in perception, the organization of information in memory, the preference for different kinds of general problem solving strategies, the speed and accuracy of decision making under uncertainty, the preference for different types of problems to solve, or the profile of intellectual dispositions, and more. Some of these distinctions describe preferences for different approaches to dealing with the challenges involved in creativity.

While theoretical and operational definitions such as the preceding ones may appear fairly straightforward, it should be appreciated that the construct of cognitive style has been associated with several problems during its tenure in the scientific arena. Such problems impact on the validity of the construct. The more important of these can be grouped into six major issues.

First, most style researchers have made a distinction between cognitive styles and cognitive abilities. While cognitive styles are defined as describing *how to*, or in what way we process information, cognitive abilities are defined in terms of *how well* we process information. Cognitive abilities capture how much, how well, or how accurately we process visual, semantic, or numerical stimuli, and are rooted in structural conditions that do not leave much room for choice. In contrast, cognitive styles describe differences in dispositions to process information in certain ways, and are anchored in functional conditions that provide more room for choice in, for example, the types of general strategies we tend to employ when working on problem solving tasks. Cognitive style may also determine whether we primarily perceive wholes or parts in dealing with tasks of problem solving, learning or creativity. Lack of, or low, correlation between style and ability has commonly been seen as a necessary condition for a style construct to be valid. It seems reasonable to accept that under certain circumstances, cognitive ability and style should be rated. Certain tasks suit certain styles: brighter people may be able to adapt their style to suit the nature of the task. Further, preferences possibly 'grow out of' abilities. Thus, a facility with numbers may lead to a preference for convergent thinking, while a facility with words may lead to a divergent thinking style. Not all the postulated style constructs have, however, controlled for influences from abilities. Some style constructs have also been shown to have alarmingly strong correlations with measures of abilities, which puts them in serious jeopardy in terms of fundamental construct validity – that is the two are essentially indistinguishable.

A second issue is that the psychological basis for many style constructs may be seen as an accumulated personality impact on cognitive processes. This means that our motivational dispositions based on the traits in the five factor model of personality may dispose us toward using certain modes of information processing unless the task demands in the situation 'force' us into other modes of processing. It is just as conceivable that differences in personality profiles may correlate with preferences for cognitive styles. Moderate correlations thus must occur, yet the same requirement for incremental validity in terms of accounting for variance beyond what is explained by relevant personality factors, or other relative advantages, must be shown for cognitive styles to survive as a sound, autonomous construct. Under these conceptual requirements, the construct of cognitive style can be described as being placed at the intersection between personality and cognition. In this capacity it may serve an important function as a bridge concept that may bring personality and cognition together in a concerted way to optimize performance. Indeed, this is how the concept was initially conceived over 80 years ago. An implication of this is that several cognitive styles should be more strongly related to various personality constructs than to intelligence, and that style should be seen as a disposition more than as a situational preference. Very few, if any, style studies have controlled adequately for the effects of personality in the predictions of performance on cognitive tasks.

A third issue is related to a distinction between task specific strategies versus higher order strategies, sometimes called meta-strategies or executive functions. Most researchers in the field have chosen the latter option, where styles are held to be more strongly associated with more general, or higher order strategies, rather than task specific strategies. An implication of this is that styles should be relatively more consistent across tasks and stable over time than task-specific cognitive strategies. This issue has, however, received relatively little attention in research on cognitive styles.

A fourth issue is that style theories have flourished without the existence of any unifying model or framework for the several style constructs. Some progress has nevertheless been made in this regard, and Richard Riding and Stephen Rayner describe a theory where a large number of cognitive style constructs are organized under two superordinate style dimensions called verbalizer-visualizer and analyst-wholist styles. The first of these describes typical modes of mental representations and the second pertains to the way in which the individual organizes information. Other researchers have suggested that style theories can be described as cognition-centered, personality-centered, and activity-centered, whereas a later classification divided style constructs into Type 1 (preference for unstructured tasks, norm breaking and original thought), Type 2 (preference for structured tasks, conformity, respect for rules and authority), and Type 3 (situation specific adaptability of Type 1 and Type 2 styles). Maria Kozhevnikov argued that most style constructs could fit into a model where there are two levels or dimensions. The superordinate dimension was seen as related to executive cognitive functioning (associated with flexibility in the choice of lower level strategies), and (at least) two subordinate dimensions seen as describing either low-level information processing (like perception) or more complex

cognitive activities (like decision making). Despite these attempts, no agreed upon, clear typology of cognitive styles yet exists.

A fifth issue is whether style should be defined as being bipolar or unipolar. In the former case, one end of a style continuum should be associated with certain characteristics, while the other end would be associated with the opposite characteristics. People located in between the extreme scorers are seen as being more flexible or mixed in their dispositions. To investigate this issue more closely requires that each pole is operationalized separately, and that scores on both poles are negatively correlated with each other. Bipolarity can be inferred to the extent that there is a relatively strong and negative correlation between the two polar opposites, with lack of incremental predictive validity for one end of the continuum when statistically controlling for the other. Related to this issue is also the position taken by Eugene Sadler-Smith that, for example, intuitive-analytical cognitive styles actually describe two different cognitive processes, with a versatile style combining the two, or as Chris Allinson and John Hayes have posited, that the analytic-intuitive dimension describe two poles on a continuum. A further distinction in this respect is described as mobility-fixity, where mobile dispositions describe a tendency to use both styles, while fixity describe a tendency to use only one. Associated with the bipolarity issue is also the hypothesis that both poles of stylistic constructs should, in the general sense, be value free. In practice, however, one pole in most style constructs has tended to be more valued than the other, which is rarely the case.

The sixth issue concerns whether cognitive style theories should operate as self-contained models or be related to more general theories of cognition and eventually also linked to theories of personality in a broader perspective. The latter alternative implies that styles should be defined in ways that make their operationalizations meaningful in a perspective defined by the style construct itself. This has not always been the case for style theories, and a large number of theories have been formulated based on loosely defined ideas. Samuel Messick has made important strides in anchoring conceptualizations of cognitive styles more firmly, and suggests that styles evolve around underlying profiles of abilities, traits, or motives, which is strongly akin to the perspective advocated in this article. Moreover, while styles can be quite substantially influenced by both ability and personality, they should also be seen as shaped by individual experiences and adaptations. Finally, based on the review by Kozhevnikov, it can be suggested that cognitive styles have adaptive functions and that they typically describe dispositions towards using different kinds of heuristics that we use to process information about our environment. In this regard, style theories can be naturally related to theories of information processing, for example within the heuristics and bias tradition in the domain of judgment and decision making.

Despite the challenges associated with the six issues above, cognitive style has been a popular construct in psychological and educational research. Since the early 1950s and earlier, a large number of studies on style constructs have been published in journals and in edited and authored books. A number of these have touched on the relationship between cognitive styles and creativity. Moreover, several theories have been

postulated over the years, and cognitive style has indeed been looked upon as a promising construct within the field of creativity. The main reason for this is that it has been seen to have the potential to supply some of the missing pieces of the puzzle from the classic experimental research on human cognition. Here individual differences generally have been perceived as irrelevant, or as a 'nuisance' in terms of error variance. The construct of cognitive style has been used to describe *how* individuals process information in different ways and to show that the inclusion of data on individual differences adds to our knowledge of human cognition beyond the reaches of both classical experimental research and multivariate studies of intelligence. As regards the relationships among cognitive styles, problem solving and creativity, an important issue has been to investigate whether people solve problems or create novel and useful solutions in predictively different ways. Below, we briefly present a number of style constructs, although more such constructs, like convergent-divergent and verbalizer-visualizer styles, could have been presented if space had permitted.

Theories of Cognitive Styles and Their Relationship to Creativity

Classic Theories

Cognitive controls

Work on cognitive controls began in 1951 and was partly based on psychodynamic theory. A cognitive control was seen as a hypothetical construct in the sense of a delay mechanism that directs the expression of needs in socially and situation-specific acceptable ways. Seven different controls were theoretically specified and operationalized: tolerance for unrealistic experiences, conceptual differentiation, constricted-flexible control, levelling-sharpening, scanning, contrast reactivity, and field articulation. These several control constructs were originally measured experimentally, while other measurement methods were developed later. Cognitive styles were defined as patterns of controls.

As regards the validity of the cognitive control theory, several criticisms have been put forward. It has been argued, among other things, that various controls did not appear consistent across different studies, and that correlations with different criteria were generally low, and seldom significant. There have been theoretical inconsistencies associated with cognitive control research, and it has been argued that cognitive controls to a large extent were treated as value directional and unipolar.

The relation between cognitive controls and creativity was investigated in a sample of gifted children. The studies did not yield consistent results concerning the relationship to creativity. It turned out to be possible to isolate three styles (clusters) in this sample, which may imply that there are differences in the stylistic dispositions of gifted students beyond the level of ability. However, based on contemporary standards for validation, the limitations pointed out in the preceding criticism lead us to the conclusion that there is insufficient support for the validity of stylistic constructs associated with cognitive controls. Consequently, the relationship to creativity is also uncertain.

Field dependence–independence

In 1954 research was initiated on field dependence and independence as a stylistic construct. This construct was defined as a process variable, representing the degree of autonomous functioning in assimilating information from the self and field. On the basis of several later theoretical and empirical developments, field dependence–independence was defined as a bipolar construct. Specifically relevant for creativity was the thesis that field-independent subjects are better at cognitive restructuring, while field dependent subjects are more socially adept because they are more sensitive to external referents. Moreover, field-dependent and field-independent subjects could be *fixed* (those who appeared not to have any capacity for the properties associated with their opposite style), or they could be *mobile* (those who appeared to be more flexible with regard to the two types of styles). Thus, some people were seen as more flexible than others with respect to their stylistic dispositions. These stylistic properties were measured with two different tests. One was the Rod and Frame Test, where the task involved ignoring a visual or postural context to locate a true vertical. The other was the Embedded Figures Test, where the task involved locating a previously seen simple figure in a new figure where the simple figure had been embedded within a more complex design.

Results from several studies supported the hypothesis that field-independents are more creative than field-dependents. Moreover, it has been argued that mobile subjects would be more creative because of their ability to move flexibly between the two stylistic modes. While this work seems interesting from a creativity perspective, it is nevertheless necessary to interpret these results and ideas cautiously given the present conceptual status of the theory of field dependence–independence.

The theory of field dependence–independence was very popular and generated a substantial number of studies until around 1980, when interest in the construct declined.

During the eighties serious criticism was raised against this theory, for example, the frequently found high correlations with measures of general mental ability and, particularly tests of spatial ability. Based on such findings a cloud of basic doubt lingers over the concept of field dependence–independence as a pure measure of style versus ability. Several recent attempts to reformulate this theory indicate that research on field dependence–independence might continue in spite of previous challenges and disappointments.

Reflectivity–impulsivity

This cognitive style dimension relies on differences in decision speed under conditions of uncertainty. Its primary measure was the Matching Familiar Figures Test, where individual differences in speed and accuracy of decision making (conceptual tempo) under uncertainty were measured. Time to make decisions and errors in the accuracy of decisions were combined to categorize children as impulsives or reflectives, or more precisely as fast-responding/high-error, fast-responding/low-error, slow-responding/low-error, or slow-responding/high-error types. Previous reviews of this theory brought, on the whole, positive conclusions for reflectivity–impulsivity as a style construct. The overall conclusions from these reviews show that reflectivity–impulsivity is moderately stable and

generalizable across similar tasks. Task performance for reflectives and impulsives seems, however, to be dependent on task demands. Thus, reflectivity–impulsivity may describe a bipolar construct, where each pole has differential value. Impulsivity has, however, been found to be associated with lower intelligence and lower motivation than reflectivity, and the question is whether this cognitive style distinction yields results that are significantly beyond those obtained with measures of general mental ability.

The study of the relationship between reflectivity–impulsivity and creativity has provided mixed results. No significant differences were found among conceptual tempo groups on a series of common creativity and problem solving tasks. It has, however, been shown that fast/accurate and slow/inaccurate subjects obtained greater originality scores than slow/accurate and fast/inaccurate subjects. Significant relationships also have been obtained between reflectivity–impulsivity and some facets of musical creativity, and reflective subjects have been shown to score higher than impulsive subjects on the Torrance Tests of Creativity. Although no clear pattern in these findings has emerged, where significant relationships have been obtained, reflectives have had higher scores.

Recent Theories

Theories in the holist – analytic category

In Richard Riding and Stephen Rayner's organization of style theories a number of style constructs have been placed in the holist-analytic category and some of these bear clear relevance to creativity. Among these, the style theory advanced by Michael Kirton in 1976 has made a special contribution to the study of creativity. In this theory Adaptors and Innovators (A-I) are seen as describing two qualitatively different and consistent individual approaches in preferences for different ways of solving problems and approaching tasks involving creativity and in decision making. Kirton makes a distinction between style and level of creativity. Level of creativity is measured through evaluation of the quality of people's creative ideas or products. Style of creativity is supposed to capture the different approaches of adaptive creativity directed toward improvements within an existing framework, compared with innovative approaches directed towards basic change of the existing state of affairs. However, individuals are not seen as being fixed at either end of the A-I continuum, and when individuals depart from the behavior associated with their preferred style this has been called 'coping behavior.' It is argued that differences along the adaptive–innovative continuum should be unrelated to variations in the level of creative performance.

In several studies, it has been demonstrated that the Kirton Adaptor–Innovator inventory (KAI) typically does not in general correlate with measures of intelligence. On the other hand, a relatively strong relationship has been obtained between scores on several personality traits and the KAI, for example, between KAI scores and the sensation seeking trait. This means that Innovators tend to have a higher need for stimulation and excitement than Adaptors. Other researchers have found that the A-I continuum is positively related to Extraversion and Openness, and negatively to Neuroticism

and Conscientiousness in the five factor model of personality. Based on these style–intelligence–personality correlations, basic requirements for a theory of cognitive style seem to be fulfilled. Yet, there seems to be a need for studies showing that the KAI adds to prediction of creativity by abilities and personality.

As regards creativity, the main bulk of research shows that KAI scores are uncorrelated with various measures of divergent thinking. This has been taken as support for the idea that there are different types of creativity along the adaptive–innovative dimension that are independent of level of creativity. Generally speaking, however, zero correlations as such do not support the hypothesis that there are different types of creativity; they only support the idea of unrelatedness. Moreover, some studies indicate that Innovators obtain higher scores on some measures of creativity. On the other hand, it was found that Adaptors perceived creative products in their workplace as more logical, useful, and adequate than Innovators, while Innovators perceived creative products as more original and transformational than Adaptors. These findings were interpreted as supporting Kirton's theory that there are different types of creativity. However, self-reports on both style and creativity evaluations do not necessarily support this idea.

Although Kirton's theory is interesting, the bulk of research on the theory is correlational or factor analytic. This implies that some of this research may lack the necessary controls to permit making causal inferences. This is a limitation when it comes to testing the main hypothesis in the adaptation–innovation theory. Further efforts should thus be made to demonstrate experimentally that A-I indeed utilize qualitatively different strategies uncontaminated by level of creativity, and that these strategies have different implications for the direction of effort in creativity, problem solving, and decision making. Kirton's idea of a distinction between the style and the level of creativity is useful, but the support for this idea is so far too limited to warrant such a conclusion. Arguments have also been presented to the effect that the distinction may be conceptually flawed. Specifically, it has been argued that the concept of innovation/innovative logically requires the concept of creativity to be involved, whereas the concept of adaptation/adaptive does not.

Another theory in the holist–analyst category of styles is the theory of Assimilator–Explorer (A-E) cognitive styles which has been proposed by Geir Kaufmann and later elaborated by Øyvind Martinsen. The theory of A-E styles describes individual differences in dispositions toward using problem solving strategies, and Kaufmann based his original theory on cognitive schema theory with special reference to Piaget's core concepts of assimilation and accommodation. Assimilators are seen as more rule bound in problem solving behavior, and as having a disposition toward interpreting new events in terms of existing knowledge. In an expansion of Piaget's concepts, Explorers are seen as having a disposition toward novelty seeking, which manifests itself in a search for new types of solutions and new ways of solving problems without any external pressure to do so. The A-E styles have been suggested to be partially rooted in biologically-based preference for stimulus variability versus stimulus stability.

This stylistic distinction also has been found to have several correlations with measures of personality, while they are

uncorrelated with general intelligence. The A-E styles correlates quite strongly with a motivational factor, and also correlates with Neuroticism, Agreeableness, and Conscientiousness, and with Openness in the five factor model of personality. Significant differences have been found in mean scores for students in different types of educational settings, with art students having the highest scores (more explorative). A significant correlation also was found between the A-E styles and scores on a creative activities checklist (Explorers having higher creativity scores), but there was only a weak, yet still significant, correlation with measures of verbal and figural fluency. Taken together, the correspondence between the A-E theory and the pattern of empirical findings is consistent with the requirements in basic definitions of cognitive style.

Other studies have sought to validate core premises of the A-E theory more specifically. It has been found that Assimilators need task-relevant experience to use their preferred mode of processing efficiently, while Explorers are more proficient when exploring the task environment when they have low levels of experience. It has also been found that Explorers and Assimilators performed differently based on instructions to utilize different types of problem solving strategies on creative problem solving tasks. This finding was interpreted as experimental evidence for the idea that people with different stylistic dispositions normally utilize qualitatively different problem solving strategies where the experimental instructions may have compensated for task specific challenges associated with the poles of A-E styles.

In an extension of A-E theory, it has been argued that A-E styles can be seen as a relevant indicator of task-specific competence, but that such task-specific competence does not necessarily lead to superior performance. Other conditions contribute to impairing or facilitating performance beyond the degree of compatibility between stylistic dispositions and task demands. In this regard interactive effects between stylistic disposition, degree of task-relevant experience, cues in the situation such as solution hints, the salience of motivation arousing conditions, as well as positive mood, together may influence performance. This dynamic interplay may be explained by a theory of optimal motivation for the task, where task characteristics, styles, affect arousing conditions, and achievement motives together determine the quality of performance. This indicates the difficulty of research in this area.

In general, it can be argued that the A-E styles seem to have a base in human personality, are orthogonal to measures of general intelligence, and predict performance on creativity tasks in interaction with other influences. The theory has the advantage that it can be coherently integrated with theories of personality and achievement motivation, and recent theories of information processing. In such theories creative problem solving is conceptualized as search in large problem spaces, and/or as diverted search in an incorrect problem space. The perceived task structure is determined by the availability of solution constraints and adequate heuristics in dealing with such constraints. It has been posited that the A-E styles describe individual differences in preferences for such heuristics. Research on A-E styles may also shed new light on the relationship between motivation and creative problem solving, as well as the relationship between positive mood and creative problem solving. Consequently, this theory may have fruitful

implications in several areas of research extending beyond its 'hub' in the domain of problem solving.

Thinking styles

In 1988 Robert Sternberg based his style theory on a governmental metaphor which rests on an assumption that people govern themselves in a similar way to societies. The thinking styles describing different aspects of self-government include: functions, forms, levels, scopes, and leanings. The three major *functions* are the legislative (creative), executive (implementive), and judicial (evaluative) styles. Four major *forms* of government are the monarchic (preference for one goal at a time), hierarchic (preference for multiple goals ordered in a hierarchy), oligarchic (preference for multiple goals, where each is equally important), and anarchic (avoids rules and systems). Two basic *levels* of government are the global (preference for general problems demanding abstract thought) and the local (preference for tasks that require detail and precision). Two domains in the *scope* of government are the internal (preference for tasks that allows people to work alone) and the external (preference for tasks that allow working together with others). Two core *leanings* are the conservative (preference for the familiar and traditional) and the liberal (preference for going beyond existing rules and regulations).

Sternberg's theory shares basic similarities with other theories of cognitive styles: styles are placed at the interface between personality and cognition, express the manner of cognition, and should be uncorrelated with intellectual capacity. However, thinking styles can still be related to more local domains of capacities. Sternberg's theory, like Kaufmann's, has been developed within a theory of intellectual functioning, which may simplify both the operationalization and the evaluation of the stylistic dispositions compared with other style theories. Still, cognitive styles have typically been defined as bipolar constructs, while thinking styles are defined as unipolar constructs that together create a stylistic profile. The bipolarity assumption that is common in most theories of cognitive styles is thus rejected in the theory of thinking styles, although this may be an empirical question.

Sternberg and colleagues Elena L. Grigorenko, Li-Fang Zhang and others, have conducted a number of studies on the theory during the last decade. Among the most central findings are that nonsignificant correlations have been obtained between these stylistic dispositions and measures of IQ and grade point average (GPA). However, correlations between several aspects of thinking styles and grades have been reported, where the direction and magnitude of the correlations were contingent on the type of subject and education the students were taking. This is a finding that supports the idea that styles describe competencies in local domains. A number of correlations have also been found between the various thinking styles and other style measures, as well as with personality types.

In more recent conceptualizations of the theory, three superordinate dimensions of styles have been described, with different aspects of thinking styles included within each. The first of these, labeled 'Type 1 style,' includes the legislative, judicial, global, and hierarchical facets. The second, labeled 'Type 2 style' includes the executive, local, monarchic, and conservative facets. The third style, labeled 'Type 3 style,'

includes the oligarchic, anarchic, internal, and external facets. A number of studies have shown that the Type 1 style is associated with openness to experience and conscientiousness in the five factor model of personality, higher adaptiveness, higher self-esteem, enhancement of positive emotions, the motive to approach success, better mental health, and more. Type 2 style has been associated with neuroticism, the motive to avoid failure, and other typically conceived, negative influences, while tendencies to have higher academic achievements were also evident in association with this style. Further studies have focused on educational issues. The theory has moved away from a position where all styles have equal value.

Sternberg included styles in his theory of creativity and found negative relationships between creativity and the executive, conservative, and monarchic styles. A combined score on these styles was significantly and negatively correlated with an overall measure of creativity. Contrary to theoretical expectations, the legislative style was not correlated with the measures of creativity. However, more recent studies have shown that giftedness was associated with Type 1 style and that creative writers also scored higher on the same type of style.

Taken together, a growing number of studies have strengthened the validity of the theory of thinking styles. The theory of thinking styles also seem to be comprehensive, as other theories, like the A-I and A-E distinctions above, may be more narrowly focused. Yet, there seems still to be a lack of experimental studies in research on thinking styles, and such studies may be necessary to make more valid, causal inferences about core propositions in the theory.

Approaches related to creative problem solving

Other theories of styles have, in various ways, been related to the process of creative problem solving. One such theory has been developed by Min Basadur. This theory maintains that there are two main stylistic dimensions, one describing two different ways of *acquiring* knowledge, and the other relating to two different ways of *using* knowledge. The two different ways of getting knowledge are through experiencing and ideation, and the two different ways of using knowledge are through thinking and evaluation. Various combinations of these stylistic attributes yield different typological interpretations, and these are labeled Generator, Conceptualizer, Optimizer, and Implementor. This measure seems to be based on a measurement technique that has some limitations while the constructs themselves seem to echo the idea of problem finding and problem solving, which is also related to creative producing and creative solving of problems and ideas.

A second theory in this category has been developed by Gerard J. Puccio who maintained that there are four different individual preferences related to the process of creative problem solving. These four preferences were labeled Clarifier, Ideator, Developer, and Implementer. The Clarifier preference describes aspects of data finding and problem finding in the Creative Problem Solving framework. The Ideator preference describes aspects of mess finding and idea finding. The Developer preference describes aspects of solution finding and the planning aspects of acceptance finding. The Implementer preference describes action oriented aspects of acceptance finding. The theory and its measure have been developed in stages, and currently factor analyses and correlational analyses with other

popular and creativity relevant measures have been undertaken. However, it awaits further rigorous analysis.

A third theory has been called VIEW and assesses problem solving style. It has been developed by Edwin C. Selby, Donald J. Treffinger, Scott G. Isaksen, Kenneth J. Lauer, and others as a novel integration of constructs, while it also seems to be operationalized in a way that is close to some existing style and type constructs. Its main focus is individual differences in relevant aspects of creative problem solving, and it measures three styles. The first style is labeled *Orientation to Change* and describes a distinction between Explorers and Developers. The second style is labeled *Manner of Processing* and describes a distinction between External and Internal ways of processing. Finally, the third style is labeled *Ways of Deciding* and describes a distinction between a People and a Task orientation. The items in this inventory represent what may be conceived of as semantic differentials which may represent true opposites or contrasted constructs. Factor analyses support the conceptual three factor distinction, and a number of correlations with type and other style measures support the theory's initial validity. Also this theory seems to generate new research.

Discussion and Future Directions

Although cognitive styles indeed seem to offer an important approach to studying creativity, it is clear that cognitive style can only be part of a theory to explain creativity. This is also evident in several theories of creativity and related processes where cognitive styles have been merged with various personality traits, motives, abilities, experience, and social and training factors. In most of these theories, set-challenging or novelty seeking versus set-accepting and rule following thought have been emphasized as important for creativity.

Even in the present context of many cognitive style theories, varying findings on associations between cognitive styles and creativity, and the various theories of creativity that include cognitive styles, we may still point to some important limitations. In this regard there seems to be *three* major areas that may be improved in future research. The *first* concerns the validity of cognitive style constructs, the *second* concerns the design of studies on cognitive styles and creativity, and the *third* concerns the perspectives on style-creativity research.

First, although interest in style theories may have had an upswing in the last decade, the validity of several cognitive style constructs remains unproven. Through the history of style research, close links have been found both between intelligence and styles and between various measures of styles and personality. Further research is necessary to settle more definitively whether cognitive styles represent an *autonomous* construct, or whether it eventually boils down to a mix of stylistic expressions of ability and personality constructs. The older theories, like field dependence-independence, must be developed in line with newer theories to further validate the uniqueness of this construct. On the other hand, the more recent theories of adaption-innovation, assimilation-exploration, and thinking styles, and problem solving styles stand in need of sharper examination on the merits of their incremental validity against ability and personality factors. That is, does one advance or handicap the field by mixing

personality and ability/preference and power/concepts into style? After all these years the jury remains out on this issue.

One interesting path for future style research can be inspired by research on compound traits, or emergent traits, which has a long history in research on personality. Such traits, like integrity, emotional intelligence, managerial potential and more, are typically measured by criterion referenced tests that purport to measure specific behaviors in applied settings. Common for several such traits is that they are factorially complex and typically related to Neuroticism, Agreeableness, and Conscientiousness. In a related way, styles may be seen as describing specific, cognitive phenomena that mediate profiles of personality traits and/or abilities. Consequently, to the extent that style theories can be placed in a conceptual space with personality and ability constructs and shown to have some kind of advantage beyond the traits that they originate from, it would further validate style as a useful construct in psychology. A clarification of such ideas would also explain further the factorial complexity typically observed for some style measures and the multiple personality correlates for the same measures. In this regard, styles could be classified as Intellectually focused Personality Scales (IPS) with similar potential and limitations as the compound traits previously mentioned, or Criterion focused Occupational Scales (COPS). These ideas have been elaborated by Adrian Furnham and others. Elena L. Grigorenko recently speculated about whether styles actually share some of the genetic influence on intelligence and personality, but pointed out that genetic research on styles remains nonexistent, although it is likely to show heritability.

Second, the research designs that are most frequently applied in stylistic research on creativity still seem to be non-experimental. This limits understanding of the results and the possibilities of making causal inferences about style-creativity relationships. If we are to investigate the possibility that cognitive styles, for example, describe different ways of being creative, it is indeed necessary to apply aptitude-treatment interaction studies to shed light on such issues. In research designs like this, individual differences in cognitive styles are combined with experimental manipulations of task contents, work conditions, or other situation conditions, with the inclusion of necessary controls for alternative interpretations in terms of abilities and personality factors. Such research designs have been rare during the history of style research.

Third, it seems necessary to investigate further the relationship between cognitive styles and creativity based on different conceptions and measures of creativity. Presently we have at least four different perspectives on creativity that are important for stylistic research. The first one of these perspectives is a micro or ipsative perspective, where an individual's creativity is based on a comparison between the degree of novelty in a product or idea and that in the same person's previous products or ideas. This is an individual perspective where everyone can be seen as creative only in the sense of increasing their creativity. A second perspective is a macro or normative perspective, where a person's creativity is compared with other persons' creativity from an objective perspective. This is the invention or innovation perspective, where only a few people are creative – this is the idea of the normal distribution. The third perspective is a component perspective, which can be integrated with either of the two preceding micro and macro

perspectives. Here, the stylistic influence on various subcomponents of creativity (like insight, analogical reasoning, remote associations, ideational productivity, convergent thinking, etc.) can be studied. The fourth and final perspective is the domain specificity of creativity; will some styles predict creativity in certain domains but not in others? Style researchers need to be more aware of the several conceptual and operational distinctions that can be made in creativity research, and to adjust their research designs accordingly. Thus, the criteria and designs in style-creativity research must be specified based on *a priori* theoretical and/or operational definitions of creativity or creativity relevant processes.

Based on this overview of current research on individual differences in cognitive styles, the hypothesis that cognitive styles do indeed have a function in creativity seems quite reasonable. Still, the present theories need to be developed further in order to yield more precise information on the relations between style and creativity. Meeting this requirement also depends on further progress in creativity research where the criterion problem is multifaceted and difficult to solve. The evidence is not clear enough for a reviewer of the relationship between the style and creativity literature to despair or rejoice. The pessimist would point to the endless models, measures and theories of cognitive/learning/thinking styles, none with very impressive evidence of psychometric validity, particularly convergent, divergent, construct, and predictive validity. They would also point to the creativity literature which remains for differential psychologists something of a backwater, with little real development in terms of measurement. In other words, this is the relationship between two conceptually unclear and methodologically weak fields. The optimist on the other hand, may point to a lively applied and cross-disciplinary rather than moribund field using more sophisticated methods of research to investigate the intriguing issue of creativity. Both are very big areas and it may be that the area will best advance by concentrating on a highly specific area. Thus, if we have problem finding versus problem solving and arts versus science (divergent vs. convergent) problems, it is possible we could find the cognitive style associated with divergent problem-finding more convincingly. The importance of this level of analysis has been recognized.

Collaboration

V John-Steiner, University of New Mexico, Santa Fe, NM, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Collaboration "The process of shared creation: two or more individuals with complimentary skills interacting to create a shared understanding that none had previously possessed or could have come to on their own."

Complimentarity The ways in which collaborative partners compliment each other in intellectual expertise, working styles, and temperament.

Cultural historical theory Psychological interdisciplinary approach based on L. S. Vygotsky's

ideas with a strong emphasis on the social sources of human development.

Ensemble "A unit or group of complimentary parts that contribute to a single effect."

Networks A group of connected individuals whose closeness or distance is represented by the length of vectors on a graph.

Q sort A method to assess statements drawn from a theoretical source or practical domain along the dimension of most/least characteristic value for a participant.

Collaboration takes many forms in public and private life. In order to discover the commonalities across this diversity, this discussion starts with an introduction which highlights the growing importance of shared endeavors in our contemporary life, followed by definitions and a description of how partnerships vary from intermittent interactions to intense day-by-day transformative interactions. Following this section on patterns of collaboration is an examination of the various challenges of collaboration. These are considerable in a society that primarily emphasizes competition. When studying such a widespread phenomenon, such as collaboration, it is difficult to decide on effective methods that reveal the psychological and organizational complexity of this process. In the discussion on methodological approaches, the author presents some of the ways researchers address this challenge. Finally, we are used to studying human endeavors from the perspective of the individual, but together with the dramatic increase in collaborative activities, there has been a shift in point of view as there are an increasing number of theories which focus on human connectedness and cooperation as the basic conditions for our survival.

We are witnessing a striking increase in collaborative endeavors in the physical and social sciences, in the arts, in management, and in education. The most noticeable shift away from the solo practice of traditional research is in physics and in the biomedical sciences. The importance and the considerable expense of large scale accelerators have contributed to the joint use and coordinated work of physicists whose co-authored publications can reach a listing of hundreds of names on the title page. Biomedical research relies on the close collaboration of clinicians and laboratory scientists on the causes of serious illnesses. One of the many indices charting changes in research practices in the sciences is in the awarding of the Nobel Prize. In the first decades of its existence awards went to one individual in each of the designated domains. For example, the first physicist to receive the prize was Röntgen for the discovery of X-rays. Starting with the second half of the twentieth century, this pattern changed; the single recipients became the exception while most of the prizes are awarded to a group of collaborating scientists. Not all disciplines have

increased collaborative efforts at the same rate. Social scientists and educators do not collaborate as extensively as their colleagues in the physical sciences; however, coauthored papers and books have also increased in these disciplines.

In 2007, Wuchty and colleagues, researchers at Northwestern University, studied close to 20 million professional articles from the last 45 years in the physical, biomedical, and social sciences and in the arts. They found a doubling of the authors in the fields where laboratory research is particularly prevalent. While the role of equipment in physics certainly plays a role, there are similar but less dramatic shifts toward collaboration in mathematics, which has traditionally been considered the domain of the solitary thinker. Here, too, co-authorship has increased; mathematicians increasingly work together through the Internet.

The most recent and dramatic example of such collaboration is the Polymath Project. Timothy Gowers invited contributors online to participate in finding a solution to an unsolved mathematical problem. Just hours after the project was announced, contributions were made. Contributors ranged from high school teachers to a winner of the Fields Medal, the highest honor in mathematics. Six weeks later, Gowers announced that an elementary proof was found and a paper describing it was being written. One of the greatest contributions of this kind of open source collaboration is that it provides a record of how ideas grow, change, and are discarded. This project not only presents a better understanding of mathematical creativity, but it also provides opportunities for novices to work alongside famous mathematicians. As it is an open process, the identity of participants who make a major contribution to the problem solution can be identified.

Definition of Collaboration

One of the best definitions of collaboration was provided in 1990 by Michael Schrage. "Collaboration is the process of shared creation: two or more individuals with complimentary skills interacting to create a shared understanding that none had previously possessed or could have come to on their own."

In emphasizing the benefits of collaboration Schrage highlights the importance of complementarity.

Four patterns of collaboration were identified in 2000 by John-Steiner and coworkers. They are complimentary, distributive, family, and integrative. The most widely practiced mode of collaboration is the complimentary pattern in which expertise and disciplinary training, roles, and temperament are in complimentary relationship with each other. Pierre and Marie Curie illustrate disciplinary complementarity. (Marie's background was in chemistry, Pierre's in physics.) They also assumed complimentary roles. Marie took responsibility for a large part of the organizing work in the laboratory. Her husband provided some of the conceptual scaffolding of their research. They were also complimentary in temperament. He was retiring and cautious, she was quick, determined, and willing to engage in negotiation and compromise.

The complimentary pattern of collaboration is recognized in newer theories of situated cognition, collaborative networks, systemic use of creativity, and cultural historical theory. These new approaches consist of changes in organizational restructuring such as cross-disciplinary research and the explicit recognition of collaboration as a critical site of innovation. The increase in such endeavors reflects the reality that major societal problems cannot be solved without growing multiple-disciplined stakeholders.

Another pattern, integrative or transformative collaboration, is motivated by the desire to profoundly change existing scientific and artistic approaches into qualitatively new paradigms. The partnership of Picasso and Braque illustrates this mode of collaboration. Together they constructed cubism, a new twentieth century approach to painting which focused on the interrelation of objects. Rather than practicing clear division of labor which is common in complimentary collaborations, these partners achieved at times such complete fusion of styles that it was hard to distinguish the work of one from the other. If one partner created a pictorial innovation, the other incorporated it immediately into his own work. They were striving to eliminate individual ambition and focus on their shared vision.

Collaboration is not limited to two individuals working closely together. In 1997, Warren Bennis and Patricia Ward Biederman studied a variety of innovative communities. They refer to these as "Great Groups." Such groups have become more familiar to the general public since the establishment of computer research teams. Bennis and Bierderman describe them as follows:

Great Groups become their own worlds . . . [they] create a culture of their own - with distinctive customs, dress, jokes, even a private language. People who have been in Great Groups never forget them, although most Great Groups do not last very long. Our suspicion is that such collaborations have a certain half-life, that if only because of their intensity they cannot be sustained indefinitely.

Another approach to group creativity is the research of Keith Sawyer who has been primarily interested in improvisational groups such as jazz musicians, theater groups, and conversational partners. The definition that he quotes from the American Heritage Dictionary is that of ensembles, "a unit or group of complimentary parts that contribute to a single

effect." Other authors have focused on long term group collaborations. These include the sociologist Michael P. Farrell who in his book on *Collaborative Circles* in 2001 refers to the French Impressionists. He describes their weekly meetings, outdoor painting sessions and the informal role structure of their group ("which includes hero, jester, devil's advocate, scapegoat, and peace maker"). Members varied in the degree to which their roles were rooted in their personalities. These painters were committed to novel approaches including rejecting classical techniques by using short brush strokes and contrasting colors. "This technique brought a shimmering life to water that no one had ever achieved before. It enabled them to portray the transitory effects of light and atmosphere - goals they had been pursuing for years." The mutual support the painters provided each other helped them deal with the recurrent rejection they experienced from the French painting establishment of their time. Members of many groups who find themselves at the margin of their discipline rely upon each other for encouragement, resources, and a commitment to a shared vision. In 1975, the director Harold Clurman described in his book *The Fervent Years*, a similar pattern in his history of The Group Theater of New York.

From the beginning their emphasis was on joint creativity . . . central to the success of their collective endeavor was the development and practice of a powerful acting technique, Strasberg's adaptation of the Stanislavsky Method. His adaptation included improvisation and the use of affective memory.

Challenges of Collaboration

One of the hardest things to establish for collaborators drawn from different disciplinary traditions is the development of a shared language. Key terms have different connotations in different fields and, thus, necessitate negotiations to achieve a common meaning. This issue becomes particularly challenging when working partners attempt to write together. The term collaboration implies coordinated effort for achieving a solution to a well-defined problem for some, while others interpret it as a more open process where the end result cannot be predicted.

Another challenge is the establishment of trust among collaborators. Scientists as well as artists have more experience with competition in western societies than with working together. To overcome the practice of cautious self-interest requires sustained exploration of ideas, the discovery of complimentary skills and styles of working, and opportunities for relaxed interactions. Working partners who are evaluated for their productivity frequently worry about the ownership of their ideas or discoveries, a concern that can undermine the establishment of trust. Many collaborations emerge where intimacy or friendship is already in existence, or when partners find each other's contributions so stimulating that they work hard to overcome their socialization into competitive practices. In 1999, some studies by Palus found a lower performance in group members than by individuals working alone. These findings are based on situations where strangers spend very limited time with each other and work on problems of limited interest to them. Effective collaborations require trust, complementarity, and a shared vision. These characteristics are hard to achieve in short-term investigations.

Methodological Approaches

The most informative technique for studying group creativity is to monitor collaboration as it occurs in natural settings. In one study of young jazz musicians by Seddon in 2004, the researcher observed and videotaped 6 hour long rehearsals. A retrospective interview was also conducted with the participants who selected their own repertoire in preparation for performance. Both the participants and the researchers viewed the video tapes and helped to identify different communicative modes. In analyzing these tapes the researcher differentiated between cooperation and collaboration. The former dealing more with organizational issues, while the latter addressing the creative features of the musical performance. Of particular interest were the aspects of nonverbal communication of jazz musicians such as body language, eye contact, musical cues and gesticulation. The closest collaboration occurred when the participants took risks with "musical phrases and timing and in so doing challenged each other's musical creativity."

In 2003, Sawyer also used taped rehearsals and performances for examining the interactional features of jazz and theater improvisations. Relying on a variety of disciplines in which contingently generated verbal or musical utterances are created, he provides insight of how each participant scaffolds his/her partner's contribution. "They face a tension familiar to improvising groups: between the need for preexisting structures and the need to leave flexibility for emergent interaction to occur." The availability of audio and visual recording equipment has made it possible to study the way in which participants signal to each other a new turn or phrase in their jointly constructed, open-ended creative interactions. It also makes possible the ability to identify different levels of intensity that characterize improvisations.

A more retrospective approach is used in reconstructing sustained collaborations. The method used by John-Steiner is that of the Q sort and a subsequent joint interview with the partners. The construction of the collaboration Q sort was based on early interviews with collaborators who were asked about their motivation, collaborative roles, and working methods. Fifty statements were fine tuned to provide a broad representation of the collaborative experience. Once these items were finalized, they were printed separately on cards. Each partner is given a stack of cards to be arranged into a bell shaped distribution: a process that can entail multiple ordering. The final distribution ranges from items most characteristic of the collaboration at the high end to those least characteristic at the low end. After completing the Q sort collaborative partners are shown each other's placement of Q sort items. Differences in perception of their joint experience are reflected in the way in which each participant arranged these collaborative statements. The discussion of both agreements and disagreements provide an account and analysis of the partners' view of their shared endeavor. Since John-Steiner's original use of this method others have used it and at times modified the collaborative Q sort.

Researchers have also studied collaborative networks. One of the best known is the collaboration graph developed for the Hungarian mathematician Paul Erdős who was known for his extraordinary number of partnerships. Individuals who have worked directly with Erdős received the number '1' (they number almost 500) and those who have worked with

one of Erdős' collaborators received the number '2'. Five thousand people have been identified with that number:

In the history of scholarly publishing in mathematics, no one has ever matched Erdős' number of collaborators or papers (about 1500, almost 70 percent of which were joint works).
(De Castro and Grossman, 1999)

Researchers pursuing this method can examine the connections among collaborators both within a discipline and interdisciplinary collaborations. In Erdős' case, these included physics, economics, chemistry, philosophy, biology, and psychology.

Sociologists and the creativity researcher Dean Keith Simonton used biographic entries and published papers for their examination of coauthorship and its relationship to academic success and productivity. A related method is to look at how often a publication is cited and whether the work is solo authored or written by a team. In 2007, Wuchty and coworkers found that team authored papers are more frequently cited and that this trend has become more prevalent in recent years:

By the most recent period, a team authored paper has a higher probability of being extremely highly cited. For example, a team authored paper in science and engineering is currently 6.3 times more likely than a solo authored paper to receive at least 1000 citations.

Some researchers rely on linguistic techniques of discourse analysis in examining the reconstruction of joint experiences. These include looking at the length of utterances, sentence fragments, as well as joint productions where partners complete each others' utterances. One finding in looking at interviews dealing with collaboration by John-Steiner and co-workers is that the more highly integrated two collaborators are, the more they finish each others' sentences.

Another linguistic method also used by these authors is the examination of metaphors capturing the quality of the collaborative experience. One example of metaphors describes the costs and benefits of collaboration.

It is kind of like the (extended) Chinese family. You give up some of your freedom in a sense. On the other hand, you expand your research by such a great amount.

Theoretical Perspectives

Most theories in the human sciences address individual development. To date, the role of collaboration in human development and creativity has barely been explored. An important exception is cultural historical theory in which thinking is viewed as rooted in social practice. This approach is based on L. S. Vygotsky's theories. He proposed that people come to know the world through transforming information received in social interaction with others, and that in synthesizing diverse influences, individuals construct new concepts and strategies. Collaborative activities embody Vygotsky's social theory of human cognition.

Among contemporary writers, Howard Gardner emphasized the importance of collaborative support at the early stages of creative endeavors. His theoretical approach is a

synthesis of cognitive and Freudian approaches. He argued that the uncertainty of early explorations “in uncharted waters” requires intellectual (or artistic) and affective support. Without such support, creative individuals may experience some kind of breakdown. Gardner further wrote:

My claim, then, is that the time of creative breakthrough is highly charged, both affectively and cognitively. Support is needed at this time, more so than at any other time in life since early infancy. The kind of communication that takes is unique and uniquely important, bearing closer resemblance to the introduction of a new language early in life, than to the routine kind of conversations between individuals who already share the same language. The often inarticulate and struggling conversation also represents a way for the creator to test that he or she is still sane, still understandable by a sympathetic member of the species.

A different theoretical approach is proposed by the sociologist Michael Farrell. He is interested in the roles of leadership, marginality, and the concept of networks in investigating what he calls “collaborative circles.” He suggests that most novices within a discipline receive limited support from high prestige mentors at the beginnings of their career and turn, instead, to their peers. The connection between the individuals who eventually form a circle is at first a shared rebellion against the establishment. When dominant groups and new groups confront each other, their respective visions become more crystallized. As demographic and cultural contexts to innovation change, so does “the generating conflict over visions at the center.”

Collaborative circles provide the context to explore new ideas, and they protect participants from pressures toward conformity. Farrell also sees a role for charismatic leaders whose vision and impact help cement shared visions, but such leadership functions within a group that strives to attain relative equality, trading on each other’s particular resources. Farrell identifies a sequence of stages: the *formation* stage where members who have similar interests coalesce. The next, the *rebellion* stage is one where a dense network of participants focus on a charismatic leader. During the following *quest* stage, the circle’s own vision is developed as different members assume roles which contribute to articulating the circle’s shared perspective. Subsequently, in the *creative work* stage participants work in pairs as well as in a group and individually. Pairing is governed by the perception of equity between partners “... there is a sense that each gets a fair share of the rewards and costs.” The last two stages are the *separation* stage, and eventually, a meeting of the participants in the *reunion* stage. Throughout these stages, Farrell emphasizes roles as a central, sociological concept.

Organizational theorists have also contributed to the theoretical and applied literature on collaboration. In 1989, Barbara Gray proposed that independent actions by businesses and institutions are counter productive in turbulent times and during such times these groups are also faced with finite resources. Among the contextual factors which create incentives to collaborate, she lists global interdependence, rapid economic and technological change, and increasing competitive pressures.

While Gray recognized that there are significant differences among collaborations, she proposed a general, three-phased model of problem setting, direction setting and implementation for successful, large-scale partnerships. Collaborations are frequently beset by conflict; Gray describes a variety of

methods (including dialogs and negotiated rule-making) for overcoming discord.

Conclusions

The practice of collaboration has increased at a dramatic rate in recent decades. Projects range from two-person partnerships (like the famous joint discovery of DNA by Crick and Watson) to large-scale scientific projects, and multi-stakeholder endeavors addressing environmental and public health challenges. Nevertheless, our detailed knowledge of the processes involved in effective joint endeavors is still limited, particularly in creative domains. More research that documents and analyses ongoing collaborative projects, rather than our current, primary reliance on retrospective analyses, would provide the detail needed for a deeper understanding of this promising, and in many cases, essential activity.

Componential Models of Creativity

R J Sternberg, Oklahoma State University, Stillwater, OK, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Component In the context of this article, one of the elements that in some combination constitute creativity in a person or product.

Domain An area of creative endeavor, such as physics or painting. There is no generalized agreement as to what the domains of creativity are.

Intelligence The ability to learn and to adapt to environments.

Knowledge The organized body of information that serves as a jumping-off point for creative thinking. It is a prerequisite to creative thinking.

Motivation One's level of involvement in an activity; the energy one brings to one's creative or other activities.

Style A preference in the use of one's thinking or learning.

Definition of Componential Models

A componential model of creativity is basically one that seeks to specify the basic components, or elements, that work together to produce creative behavior. Some works on creativity hypothesize that multiple components must converge for creativity to occur.

Components Derived from Folk (Implicit) Conceptions of Creativity

Robert Sternberg, for example, examined laypersons' and experts' conceptions of the creative person. People's implicit theories contain a combination of cognitive and personality elements, such as "connects ideas," "sees similarities and differences," "has flexibility," "has aesthetic taste," "is unorthodox," "is motivated," "is inquisitive," and "questions societal norms." This work suggests that the basic components of creativity are not to be found within any single branch of psychology or any other field – cognition, personality, or social psychology, for example – but rather cross these different branches.

Components Derived from Explicit Theories of Creativity

Amabile

At the level of explicit theories, Teresa Amabile and her colleagues have described creativity as the confluence of intrinsic motivation, domain-relevant knowledge and abilities, and creativity-relevant skills. The creativity-relevant skills include (1) a cognitive style that involves coping with complexities and breaking one's mental set during problem solving; (2) knowledge of heuristics for generating novel ideas, such as trying a counterintuitive approach; and (3) a work style characterized by concentrated effort, an ability to set aside problems, and high energy. An important feature of this model is that it points out that creativity involves styles as well as abilities – that is, preferences in ways of thinking. It also points out the importance of sheer hard work in achieving creative solutions to problems.

Baer and Kaufman

John Baer and James Kaufman have proposed an amusement-park model of creativity, wherein the researchers analogize the components of creativity to the components of moving around through an amusement park. For example, one has to pick a section of the amusement park in which to walk and then has to pick specific things to do within the amusement park, just as one has to pick a domain in which to do creative work and then a specific problem or set of problems within that domain.

Gruber

The late Howard Gruber and his colleagues proposed a developmental *evolving-systems model* for understanding creativity. A person's knowledge, purpose, and affect grow over time, amplify deviations that an individual encounters, and lead to creative products. Developmental changes in the knowledge system have been documented in cases such as Charles Darwin's thoughts on evolution. Purpose refers to a set of interrelated goals, which also develop and guide an individual's behavior. Finally, the affect or mood system notes the influence of joy or frustration on the projects undertaken. Gruber's model emphasizes that components of creativity cannot be understood merely additively. That is, one cannot simply list components and ask a person whether he or she is at some reasonably high level on some or all of them. Rather, one must look at how they interact systemically in order to determine whether a person does and is likely in the future to continue to produce creative work.

Csikszentmihalyi

Mihalyi Csikszentmihalyi took a different "systems" approach and highlighted the interaction of the individual, domain, and field. An individual draws upon information in a domain and transforms or extends it via cognitive processes, personality traits, and motivation. The field, consisting of people who control or influence a domain (e.g., art critics and gallery owners), evaluates and selects new ideas. The domain, a culturally defined symbol system such as alphabetic writing,

mathematical notation, or musical notation, preserves and transmits creative products to other individuals and future generations.

Gardner

Other work complements that of Csikszentmihalyi. Howard Gardner and his various colleagues over the years conducted case studies suggesting that the development of creative projects may stem from an anomaly within a system (e.g., tension between competing critics in a field) or moderate asynchronies between the individual, domain, and field (e.g., unusual individual talent for a domain). In particular, Gardner analyzed the lives of seven particular individuals who made highly creative contributions in the twentieth century, with each specializing in one of the multiple intelligences: Sigmund Freud (intrapersonal), Albert Einstein (logical-mathematical), Pablo Picasso (spatial), Igor Stravinsky (musical), T. S. Eliot (linguistic), Martha Graham (bodily-kinesthetic), and Mohandas Gandhi (interpersonal). Charles Darwin would be an example of someone with extremely high naturalist intelligence. Gardner pointed out, however, that most of these individuals actually had strengths in more than one intelligence, and that they also had notable weaknesses in others (e.g., Freud's weaknesses may have been in spatial and musical intelligences). In the case of Gardner's model, the components are not so much additive as threshold determined. That is, the outstanding individuals Gardner cites are all people who excelled in one of the components of Gardner's model. They were not necessarily distinguished or even good at other components. For example, there is no reason to believe that Martha Graham would have excelled as a physicist, or Einstein, as a dancer!

Although creativity can be understood in terms of uses of the multiple intelligences to generate new and even revolutionary ideas, Gardner's analysis goes well beyond the intellectual. For example, Gardner pointed out two major themes in the behavior of these creative giants. First, they tended to have a matrix of support at the time of their creative breakthroughs. Second, they tended to drive a "Faustian bargain," whereby they gave up many of the pleasures people typically enjoy in life to attain extraordinary success in their careers. However, it is not clear that these attributes are intrinsic to creativity, per se; rather, they seem to be associated with those who have been driven to exploit their creative gifts in a way that leads them to attain eminence. Gardner further followed the path of collaborator Csikszentmihalyi in distinguishing between the importance of the domain (the body of knowledge about a particular subject area) and the field (the context in which this body of knowledge is studied and elaborated, including the persons working with the domain, such as critics, publishers, and other "gatekeepers"). Both are important to the development, and ultimately, the recognition of creativity.

Sternberg and Lubart

A final confluence theory considered here is Robert Sternberg and Todd Lubart's *investment theory of creativity*. According to this theory, creative people are ones who are willing and able

to "buy low and sell high" in the realm of ideas. Buying low means pursuing ideas that are unknown or out of favor but that have growth potential. Often, when these ideas are first presented, they encounter resistance. The creative individual persists in the face of this resistance, and eventually sells high, moving on to the next new or unpopular idea.

Research within the investment framework has yielded support for this model. Some of this research has used cognitive tasks such as (1) writing short stories using unusual titles (e.g., "the octopus' sneakers"), (2) drawing pictures with unusual themes (e.g., "the earth from an insect's point of view"), (3) devising creative advertisements for boring products (e.g., cufflinks), and (4) solving unusual scientific problems (e.g., how we could tell if someone had been on the moon within the past month). This research showed creative performance to be moderately domain specific, and to be predicted by a combination of six distinct but interrelated resources: intellectual abilities, knowledge, styles of thinking, personality, motivation, and environment.

In recent work, Sternberg and colleagues showed that it was possible to distinguish a factor for creative thinking from factors for analytical and practical thinking. Including creative items in assessments for college admissions increased prediction of freshman-year success in college and also reduced relative differences among students of different ethnic groups.

Concerning the confluence of components, creativity is hypothesized to involve more than a simple sum of a person's level on each component. First, there may be thresholds for some components (e.g., knowledge), below which creativity is not possible regardless of the levels on other components. Second, partial compensation may occur in which a strength on one component (e.g., motivation) counteracts a weakness on another component (e.g., environment). Third, interactions may also occur between components, such as intelligence and motivation, in which high levels on both components could multiplicatively enhance creativity.

General Aspects of Componential Theories

In general, confluence theories of creativity offer the possibility of accounting for diverse aspects of creativity. For example, analyses of scientific and artistic achievements suggest that the median rated creativity of work in a domain tends to fall toward the lower end of the distribution and the upper – high creativity – tail extends quite far. This pattern can be explained through the need for multiple and often diverse components of creativity to co-occur in order for the highest levels of creativity to be achieved. As another example, the partial domain specificity of creativity that is often observed can be explained through the mixture of some relatively domain-specific components for creativity, such as knowledge, and other more domain-general components, such as, perhaps, the personality trait of perseverance.

The various theories described above suggest at least six distinct but interrelated resources: intellectual abilities, knowledge, styles of thinking, personality, motivation, and environment. Although levels of these resources are sources of individual differences, often the decision to use the resources is the more important source of individual differences.

Intellectual Abilities

Three intellectual skills are particularly important: (a) the synthetic ability to see problems in new ways and to escape the bounds of conventional thinking; (b) the analytic ability to recognize which of one's ideas are worth pursuing and which are not; and (c) the practical-contextual ability to know how to persuade others of – to sell other people on – the value of one's ideas. The confluence of these three abilities is also important. Analytic ability used in the absence of the other two abilities results in powerful critical, but not creative thinking. Synthetic ability in the absence of the other two abilities results in new ideas that are not subjected to the scrutiny required to make them work. And practical-contextual ability in the absence of the other two may result in the transmittal of ideas not because the ideas are good, but rather, because the ideas have been well and powerfully presented. To be creative, one must first *decide* to generate new ideas, analyze these ideas, and sell the ideas to others.

Some studies have sought to test the role of intelligence in creativity through a variety of studies. Sternberg and colleagues presented 80 individuals with novel kinds of reasoning problems that had a single best answer. For example, they might be told that some objects are green and others blue; but still other objects might be *grue*, meaning green until the year 2000 and blue thereafter; or *bleen*, meaning blue until the year 2000 and green thereafter. Or they might be told of four kinds of people on the planet Kyron: *blens*, who are born young and die young; *kwefs*, who are born old and die old; *balts*, who are born young and die old; and *prosses*, who are born old and die young. Their task was to predict future states from past states, given incomplete information. In another set of studies, 60 people were given more conventional kinds of inductive reasoning problems, such as analogies, series completions, and classifications, but were told to solve them. But the problems had premises preceding them that were either conventional (*dancers wear shoes*) or novel (*dancers eat shoes*). The participants had to solve the problems as though the counterfactuals were true.

In these studies, Sternberg and his colleagues found that correlations with conventional kinds of tests depended on how novel or nonentrenched the conventional tests were. The more novel the items, the higher the correlations of our tests with scores on successively more novel conventional tests. Thus, the components isolated for relatively novel items would tend to correlate more highly with more unusual tests of fluid abilities than with tests of crystallized abilities. Sternberg and his colleagues also found that when response times on the relatively novel problems were componentially analyzed, some components better measured the creative aspect of intelligence than did others. For example, in the "grue-bleen" task mentioned above, the information-processing component requiring people to switch from conventional green-blue thinking to grue-bleen thinking and then back to green-blue thinking again was a particularly good measure of the ability to cope with novelty.

Other studies by Donald McKinnon and Frank Barron have suggested that there is a threshold effect for the role of intelligence in creativity. They suggested that intelligence is moderately correlated with creativity up to an IQ of about

120, but that after that, the two constructs are largely unrelated. More recently, however, David Lubinski and Camilla Benbow have argued that the relation between intelligence and creativity remains moderate to strong throughout the entire range of IQ.

Knowledge

Concerning knowledge, on the one hand, one needs to know enough about a field to move it forward. One cannot move beyond where a field is if one does not know where it is. On the other hand, knowledge about a field can result in a closed and entrenched perspective, resulting in a person's not moving beyond the way in which he or she has seen problems in the past. Thus, one needs to decide to use one's past knowledge, but also decide not to let the knowledge become a hindrance rather than a help.

Work by Robert Weisberg and David Perkins has suggested that knowledge plays a strong role in creativity. They have found that when more creative people are compared to less creative ones, a major difference is in the depth and breadth of their respective knowledge bases. Peter Frensch and Robert Sternberg have suggested, however, that expertise can lead to entrenchment, and hence that experts who are very knowledgeable can become susceptible to being less creative because they are used to thinking in traditional ways.

Thinking Styles

With regard to thinking styles, one kind of style is particularly important for creativity, namely, a preference for thinking and a decision to think in new ways. Sternberg has referred to this as a "legislative style." John Cacioppo has spoken of need for cognition. Joseph Fagan has found that even infants can differ in their preferences for novelty. This preference needs to be distinguished from the ability to think creatively: someone may like to think along new lines, but not think well, or vice versa. It also helps, to become a major creative thinker, if one is able to think globally as well as locally, distinguishing the forest from the trees and thereby recognizing which questions are important and which ones are not.

Personality

Numerous research investigations by Frank Barron, Donald MacKinnon, and others have supported the importance of certain personality attributes for creative functioning. At one time, the Institute for Personality Assessment Research at the University of California, Berkeley, was devoted to uncovering the personality traits linked to creative performance. These attributes include, but are not limited to, willingness to overcome obstacles, willingness to take sensible risks, willingness to tolerate ambiguity, and self-efficacy. In particular, buying low and selling high typically means defying the crowd, so that one has to be willing to stand up to conventions if one wants to think and act in creative ways. Note that none of these attributes are completely fixed. One can *decide* to overcome obstacles, take sensible risks, and so forth. However, there can be little doubt that people differ in their general predispositions toward the personality attributes of creative thought.

Motivation

Intrinsic, task-focused motivation is also essential to creativity. The research of Teresa Amabile, Beth Hennessey, and others has shown the importance of such motivation for creative work, and has suggested that people rarely do truly creative work in an area unless they really love what they are doing and focus on the work rather than the potential rewards. Motivation is not something inherent in a person: One decides to be motivated by one thing or another. However, the environment, discussed below, can play a major role in motivating people in one direction or another.

Environment

Finally, one needs an environment that is supportive and rewarding of creative ideas. One could have all of the internal resources needed in order to think creatively, but without some environmental support (such as a forum for proposing those ideas), the creativity that a person has within him or her might never be displayed. Teresa Amabile has found that in environments that do not encourage creativity, creativity is much rarer than in supportive environments.

Confluence

Concerning the confluence of components, creativity is hypothesized to involve more than a simple sum of a person's level on each component. First, there may be thresholds for some components (e.g., knowledge) below which creativity is not possible regardless of the levels on other components. Second, partial compensation may occur in which a strength on one component (e.g., motivation) counteracts a weakness on another component (e.g., environment). Third, interactions may also occur between components, such as intelligence and motivation, in which high levels on both components could multiplicatively enhance creativity.

Components of Creative Products

Robert Sternberg and his colleagues James Kaufman and Jean Pretz have proposed that not only persons, but products, can be understood in terms of different components.

First, some kinds of creativity accept current paradigms or try to extend them.

1. *Replication*. The contribution is an attempt to show that the field is in the right place. The propulsion keeps the field where it is rather than moving it. This type of creativity is represented by stationary motion, as of a wheel that is moving but staying in place.
2. *Redefinition*. The contribution is an attempt to redefine where the field is. The current status of the field thus is seen from different points of view. The propulsion leads to circular motion, such that the creative work leads back to where the field is, but as viewed in a different way.
3. *Forward incrementation*. The contribution is an attempt to move the field forward in the direction it already is going. The propulsion leads to forward motion.

4. *Advance forward incrementation*. The contribution is an attempt to move the field forward in the direction it is already going, but by moving beyond where others are ready for it to go. The propulsion leads to forward motion that is accelerated beyond the expected rate of forward progression.

Second, other types of creativity reject current paradigms and attempt to replace them or put them together in some way.

5. *Redirection*. The contribution is an attempt to redirect the field from where it is toward a different direction. The propulsion thus leads to motion in a direction that diverges from the way the field is currently moving.
6. *Reconstruction/redirection*. The contribution is an attempt to move the field back to where it once was (a reconstruction of the past) so that it may move onward from that point, but in a direction different from the one it took from that point onward. The propulsion thus leads to motion that is backward and then redirective.
7. *Reinitiation*. The contribution is an attempt to move the field to a different as yet unreached starting point and then to move from that point. The propulsion is thus from a new starting point in a direction that is different from that the field previously has pursued.
8. *Synthesis*. The contribution attempts to move the field by putting together ideas from a variety of paradigms and integrating them into a single conceptual framework.

The eight types of creativity described above are viewed as qualitatively distinct. However, within each type, there can be quantitative differences. For example, a forward incrementation can represent a fairly small step forward, or a substantial leap. A reinitiation can restart a subfield (e.g., the work of Leon Festinger on cognitive dissonance) or an entire field (e.g., the work of Einstein on relativity theory). Thus, the theory distinguishes contributions both qualitatively and quantitatively.

Domain Generality Versus Domain Specificity of Components of Creativity

An important question is whether the components of creativity are domain general or domain specific. The greatest challenge in understanding the domain generality versus specificity of creativity is in understanding the concept of a domain itself. Is literature a domain, or German literature, or modern German literature, or modern German literature in its original language, or what? Is cognitive psychology a domain, or psychology, or behavioral science, or social science? Because we have no good definition of a domain, we cannot, at this point in time, have a clear sense of exactly what domain-specificity means. Here, we recognize that domains may themselves be defined at varying levels of generality or specificity. There is not, at this time, any consensual definition of a domain.

First, creativity is, in part, an attitude toward life. This attitude can but does not necessarily extend across a variety of domains. That is, someone might adopt the mindsets that lead to creative thinking across domains, but they do not necessarily do so. Whether they do so or not will be one factor in determining the extent to which creativity is domain-general

for a given individual. For example, one such attitude is that creative ideas do not necessarily sell themselves, and hence it often is necessary to sell one's creative ideas. One might adopt this attitude, say, in one's work, but not in one's personal life, or vice versa. Even within one's work environment, one might adopt this mindset, say, in one's interactions with objects but not with people, or vice versa. So domain generality will be a function of the extent to which an individual thinks with a creative mindset across domains. More of these mindsets will be described shortly.

Much of the attitudinal effect is captured through what was called above a *legislative style* of intellectual inquiry. A person with a legislative style is someone who enjoys coming up with new ideas. The ability to generate new ideas does not necessarily go along with a desire to generate such ideas. Someone may be more comfortable in thinking in traditional ways, even if he or she has the ability to think nontraditionally. In this case, the issue is not how well one can think creatively, but rather, how much one desires to think in this way. This desire may be mediated, in part, by socialization. In some societies and some religions, creativity is discouraged. The individual may come to believe that one's conformity to existing norms is a good test of one's responsibility as a citizen. Extreme right-wing governments, for example – whatever they may call themselves – may encourage extreme conformity to a societal norm, which may or may not be for the common good.

A second variable in determining the extent to which creativity is domain-specific is knowledge. Typically, to think creatively in a domain, one has to know what is known in a domain to go beyond what is known. Someone who is knowledgeable is at an advantage to be creative in a domain. But the advantage is tempered by several factors.

First, some domains require very intensive knowledge, whereas other domains require more extensive knowledge. For example, to be creative today in neuroscience, one must be intensively knowledgeable about the workings of the brain and about the research that has been done to date on the brain. The research in this domain is expanding at a rapid rate, so one must constantly be working to keep up to date.

But in many domains, the most creative people are those who are broadly knowledgeable and whose expertise is not limited to one domain. For example, in psychology, many of the most creative scientists have been very broadly trained, often initially studying a discipline other than their primary one. For example, John Gabrieli, one of the most well-known of contemporary neuroscientists, majored in English as an undergraduate. The advantage that broadly trained people have is that they can bring ideas from one field into another. For example, Herbert Simon brought ideas from economics into psychology in his concept of satisficing. George Miller borrowed many of his ideas in psychology from linguistics. So being broadly as well as deeply educated enables one to enhance one's creative thinking, at the same time that it may mean that the individual gets a somewhat later start in his or her contributions to the field.

The situation becomes even more complicated, because expertise in a field can impair as well as facilitate creativity. One can become so used to seeing things in a certain way that one becomes less, not more creative with the development of expertise. So the acquisition of specialized knowledge does not necessarily facilitate creativity. It also can diminish it. Whether it enhances or diminishes it is largely a matter of attitude, as discussed below.

A third variable that affects the domain generality of creativity is the extent to which the environments in which one lives support creativity. An individual does not live in one environment, but rather, in a multitude of environments. For example, one's family may encourage creative thinking, but one's workplace may not, or vice versa. Certain religions are extremely intolerant of deviations from norms, and may even punish such deviations with death. So one might be allowed to be creative in one's work, but not one's religious beliefs, or vice versa, in the case that an organization for which one works insists on blind conformity to a set of norms. Someone may have creative attitudes and an extensive knowledge base, but not be allowed to use them in order to be creative.

Conclusion

Students of creativity generally agree that creativity is not a unitary phenomenon, but rather, a complex one involving distinct components. These components appear not to be strictly additive, but rather, interactive. Although there is some disagreement among theorists, there is general agreement that the components involve cognition, knowledge, personality, motivation, and environment, as well as perhaps other things.

Glossary

Artificial Intelligence It is the science and engineering of making intelligent machines, especially intelligent computer programs.

E-learning It comprises all forms of electronically supported learning and teaching. Applications and processes include web-based learning, computer-based learning, virtual classroom opportunities, and digital collaboration.

Elaboration A person's ability to add pertinent details (more ideas) to the minimum and primary response to the stimulus figure.

Flexibility A person's ability to produce differences in the trend of thought. All those ideas that differ in approach or trend are treated as one for the purposes of flexibility scoring.

Fluency In scoring for fluency, a scorer goes through the responses to the item in question carefully and strikes off those that are irrelevant and/or have been repeated.

The remaining number of responses is the fluency score.

Four P model A conceptual model for integrating four main approaches in the identification of creative talent in terms of "4 Ps", that is, 1P. Creative Person; 2P. Creative Process; 3P. Creative Product; and 4P. Creative Press (environment).

H-creativity Historical Creativity (H-Creativity) refers to something that is created or discovered which no one has ever created or discovered before (Boden, 1990).

Information processing Information processing consists of locating and capturing information, using software to manipulate it into a desired form, and outputting the data.

Originality The uncommonness of a given response. Responses given by less than 5% of the group are included and are given different weights.

P-creativity It refers to individuals who create or discover something that they themselves have never done before, even though others may have done it before them (Boden, 1990).

Simulation Simulation is the imitation of some real thing, state of affairs, or process. Computer simulations are used to study the behaviour of objects or systems that cannot be easily or safely tested in real life, such as weather patterns or nuclear blasts.

Technology Technology is the usage and knowledge of tools, techniques, crafts, systems, or methods of organization. It also refers to the application of knowledge to the practical aims of human life or to changing and manipulating the human environment.

Introduction

With the explosion of new knowledge and the expansion of global linkages, it has become essential to learn new techniques and skills for this technology dominated world. Computers are being used by people of all ages and in every profession, in their work as well as in their leisure. Many of the routine activities in today's society are performed by computers. Computers and software can also play a major role in improving the educational skills of our youth and in preparing them for the future. Our work has just begun. With computers, software, and people working together, the possibilities are endless.

The computer is becoming almost invisible and omnipresent. Washing machines, microwave ovens, cars, and televisions have already been computerized. This is the beginning of the invisible computer, which will result in virtually every electronic device known, or to be invented, being similarly computerized. Computer technology also represents access to new worlds. Computers provide information – text, audio and graphic-based – about new areas of learning, new places, new shapes, and new worlds. They stimulate new ways of thinking and analyzing problems. With computers, people are free to manipulate the information and look at facts and ideas in different ways. With increased storage capabilities, the computer is able

to take on even more critical roles as 'information grabbers' and organizers for individuals, schools, and businesses.

Hamza and Alhalabi anticipated that the 'virtual world' grows stronger and, hopefully, smarter and wiser as educators, engineers, computer scientists, and researchers of diverse disciplines attempt to locate better, more powerful ways to synthesize 'Artificial Intelligence' on the Net in order to increase productivity and efficiency in meeting future demands. Technology is in essence a manifestation of human creativity. Thus, an important way in which students can come to understand it would be by engaging in acts of technological creation. Lewis opines that technology as a context for creativity is an important area of research. Romeike emphasizes that everyday life requires creativity – and so does Computer Science.

The Computer – Its Functions

A computer is a device that computes, especially a programmable electronic machine that performs high-speed mathematical or logical operations or that assembles, stores, correlates, or otherwise processes information. A computer can do a variety of tasks easily. It works under a set of instructions, automatically accepts supplied data, processes and analyses the data and

produces the information. It does any complex problems speedily and perfectly if proper instructions or programs and data are introduced. Such unimaginable functions are possible because of its exceptional characteristics such as high speed, large memory and data storage capacity, accuracy, reliability, endurance, versatility, automation, and diligence.

Computer technology includes four basic functions: input, storage, control, and output.

1. *Input.* Input entails entering information or data into the computer, for example, keyboard, mouse, scanner, joystick, touch screen, barcode readers, optical/magnetic character recognizers (OCRs), etc.,
2. *Storage.* Once information is inputted, it is stored for eventual use on hard disks, floppy disks, compact disks (CDs), flash drives, etc.
3. *Control.* Control of stored information, as well as new input, is achieved through programs written in one of several possible computer languages that are translated by the computer's controller to the computer's assembly languages.
4. *Output.* The output or retrieval process transfers the processed information or data from the computer to the researcher, using one of a number of devices to communicate the results. The output may be displayed on a monitor, printed on paper, or recorded on disks.

In 1998, UNESCO identified 15 special properties of computers, which enhance student learning processes on a number of orthogonal dimensions. Dwight Egbert et al. believed that using computer vision research results could provide a high level of motivation to students. It is also an excellent learning tool for teaching students to integrate and use their acquired knowledge.

Computers – Its Application

Computers have entered all walks of human life across the world. They are used in a wide range of activities such as scientific research, business applications, office automation, the electronic office, stock control and sales, banking, insurance and stock-exchanging, industrial applications, space technology, communications, etc. Computers free our minds by alleviating the daily chores of writing (word-processors), making figures (drawing programs), time management (electronic calendar), communication (e-mail), information retrieval (Internet and database), presentations (MS-Powerpoint), mathematical/statistical calculations and graphs (spreadsheets), regression and predictions (multilevel modeling programs), air traffic control data, and multivariate education data (LLISREL), etc.

As observed by Maddux, Johnson and Willis, there is growing interest in the application of computer-based tools to support higher level thinking and metacognitive processes. Fitzgerald and Findlay stated that the application of computers is to enable organizations and individuals to 'learn faster' to cope with accelerating social and technological change. They also provide various possibilities for group learning, and self and peer evaluation. Computer networks, or teamwork at the terminal, open up prospects for communication, joint planning, mutual help, and moral support.

McLeod and Cropley believe that computer applications have an important role in maintaining interest, developing curiosity, and fostering the desire to master problematic situations. Computers can effectively promote learning, but only if they are used in ways which are consistent with the natural processes of learning. The analysis of several Computer-Assisted Instructional (CAI) projects reveals that computer-related learning environments are most successful when they closely resemble the natural learning environment found in the nonschool world, thereby capitalizing on the student's inherent motivation to learn. Bell suggests that educators should adhere to the following principles when utilizing computers:

- First, the computer-related learning environment should be interactive and subject to learner control, thus permitting creativity. This means that students will help plan lessons, define problems and solutions, use tests as learning experiences, and judge their own success.
- Second, students must be given the opportunity to make things work – to write and debug computer programs, for example – and should receive realistic recognition and rewards according to their degree of success.

Computers and the Internet have brought about a revolution in the world of information technology by providing searching facilities for exploring or seeking information from all over the world. Vernor Vinge states that the Internet is an international network connecting a large number of smaller networks that link computers at academic, scientific, government, and commercial institutions. The Internet provides convenient connections between computerized labs, simulations, and research databases. It also represents an enormous financial investment that is driven by the demands of hundreds of millions of consumers.

The Internet is a source of information, like a vast library which holds bundles of information in the form of texts, graphics, sound, video, etc. It also provides searching facilities for exploring or seeking information from all over the world and facilitating virtual online shopping accessible to purchasers all around the world.

E-learning is a flexible, quick and high quality learning method, which uses various learning tools of the Internet. Worldwide video conferencing is an emerging service on the Internet, which allows a group of users located around the globe to talk and interact with each other as if they were sitting and discussing in a single room. The Telnet and Usenet services allows a group of Internet users to exchange their views/ideas/information on some common topic, which is of interest to all the members belonging to the group. Such groups are called *newsgroups*.

The Computer as Productivity Tools

The computer itself is called a tool, tutor, and tutee. Hunt and Shelley believe that the computer can ease the load of administrative duties, leaving the teacher more time to concentrate on teaching. Scales and Snieder emphasized that modern experimental science would be impossible without computers. The key technologies inculcate the Internet and the applications enable the network, such as audio conference,

videoconference, e-mail, and collaborative software. Activities such as writing, literature searching, information management, idea management, and data analysis are the main functions of the computers.

According to Saunders and Thagard computers are unusual machines in being not only tools but also tools for making tools. The computer has its key metaphor of a carpenter's workshop (wood-working), which is similar to building a machine capable of designing furniture, and then building the product. When we want to make things with wood, we are allowed to use the brace and bit for drilling holes, and the handsaw for cutting. The manufacturers of Apple Macintosh computers stated that the ability to produce and the time taken were limited to the power of the tools and our energy in operating them. Now we use an electric drill, power sander, and circular saw, enabling us to make many more things in less time, with greater precision, and using much less energy. Similarly, computer software could be used as an efficient tool in problem solving for affluent outcome. Computers can be used as research tools to carry out various tasks. The use of software and the Internet deserve special mention here. The Internet is the newest innovation in the world of educational computing and it is being promoted by many as the most powerful tool for learning ever invented.

UNESCO opines that the computer is evolving into a tool to facilitate learning of most of the educational properties of older technologies (books, radio, film strips, phonograph records, television) with at least equal if not greater convenience of use plus communication capabilities. Computers can also be very accommodating – they can reach students at different study levels, any time of the day or night. Additionally, the sense of independence and accomplishment a computer offers children helps fuel their self-confidence. Alden has expressed that relying on a computer as a tool may be one of the most effective ways to build both a child's learning skills and self-esteem.

Spender appraises that as we move from book culture to digital culture, we are on the brink of being able to rethink the entire process of teaching and learning. Adler strongly believes that the challenge is in helping children learn to use a home computer to bring out their imagination and curiosity – and learn when to turn it off in favor of more traditional playthings.

Computers are tools, not slave-masters, are inert, unresponsive, incapable of thought, but we can accomplish much through and with them. Wilson says, that if you are a creative writer, you'll make the best use of whatever is the current writing tool – and that is now the word-processor. In much the same way that a word-processor does not directly help a writer create a better story, the computer is a tool enabling the writer to do some things better, such as moving text around, easy deletion, and inserting text in the middle of sentences.

Sally Bowman Alden, the Executive Director of the Computer Learning Foundation, has identified six key areas that all children should be exposed to in using computers and software as tools – tools for learning, creativity, productivity, research, communications, and entertainment.

1. As a learning tool, computers can help develop memory skills, offer after-school study or tutoring sessions, allow children to experiment, and investigate abstract science and math concepts through simulations.

2. As a creativity tool, computers provide access to an infinite color palette and a fine-tuned keyboard keeps children busy creating art and music.
3. As a research tool, computers offer children access to information that wasn't available at their school or local library.
4. As a communications tool, computers and software can enable children to share experiences with their next door neighbor or with other children as far away as Europe or China, all electronically.
5. As a productivity tool, computers and software programs such as word processing, databases, and spreadsheets can also help children work more efficiently.
6. And, as an entertainment tool, computers and various game software keep children involved for hours; and just like Monopoly, many entertainment programs help children develop important skills.

Saunders and Thagard speculated that computers often do unexpected things, but rarely in a way that leads to new discoveries. According to Boden, creativity is just an unpredictable combination of ideas. If so, computer modeling of creativity could be simple, and could combine ideas at random until something creative emerged. If not, we must find a more adequate theory of creativity before computer creativity is possible.

Creativity – Its Definitions

Guilford viewed creativity in terms of his theory of the structure of the intellect (SOI), derived from factor analytic procedures that divergent thinking enables the individual to be more flexible and fluent, involving a richer flow of ideas and resulting in some novel or creative solution. Creative thinking is problem solving. In convergent thinking the person follows the prevailing mode of thought, information, and action to arrive at one right answer, which could also be attained by other individuals. Taylor suggests that creativity operates at five levels: (1) expressive creativity, (2) productive creativity, (3) inventive creativity, (4) innovative creativity, and (5) emergentive creativity.

Repucci reviewed 50–60 definitions and classified them into six major groups or classes. These groups are not mutually exclusive, since each definition may contain elements which fall into different classes. The first class of definitions are labelled as: (1) Gestalt or perception, (2) end product or innovation oriented, (3) aesthetic, (4) psychoanalytic or dynamic, (5) solution thinking, and (6) varia.

Welsch reviewed 22 definitions of creativity and proposed the following definition:

Creativity is the process of generating unique products by transformation of existing products. These products, tangible and intangible, must be unique only to the creator, and must meet the criteria of purpose and value established by the creator.

Phyrooj reveals that all are creating something. Their creative energies are being manifested in different ways and styles. According to de Bono creative thinking is concerned with changing concepts and perceptions (i.e., lateral thinking). Lateral thinking is reserved for the specific techniques and

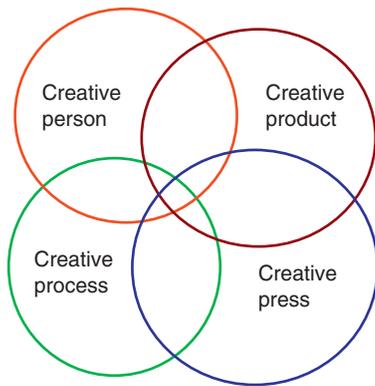

Figure 1 4 Ps (Person, process, product, and press).
(Source: Firezti, 1993, p. 262).

tools that are put forward as a systematic way of getting new ideas and new concepts.

In fact, as Gulati says, creativity makes an object or activity better, richer, more productive, fruitful, and aesthetically satisfying. Creativity is multifaceted. According to Runco the generation of new and valuable ideas is a core component in the ability of individuals and groups both to respond adaptively to change and to envision and bring about change.

Isaksen, Murdock and others revealed that creativity research, rather than having one universal definition, has used a variety of definitions, theories, and assessment approaches. Despite the apparent confusion and contradictions resulting from the use of multiple definitions, some degree of agreement has been reached.

A widely known and accepted concept of creativity, called the 'Four P' model, is based on the assumption that creativity can be defined as a holistic multidimensional concept. Rhodes developed a framework for a unifying approach to creativity; he collected 56 different definitions (40 of creativity and 16 of imagination) and observed that these definitions overlapped and intertwined, forming four strands: (1) creative person, (2) creative process, (3) creative product, and (4) creative press or environment.

Similarly, Mooney hypothesized a conceptual model for integrating four main approaches in the identification of creative talent: (1) the environment, (2) the person, (3) the process, and (4) the product. Further, Isaksen (1987) extended Rhodes's approach when he introduced the concept of the '4 Ps' (creative person, creative process, creative product, and creative press (environment)) of creativity as an overlapping Venn diagram (see Figure 1).

1. *Creative person*. Clustered around personality-related traits and abilities, motivational and affective states, and behaviors of the person to create something new (e.g., Torrance, Barron, Sternberg, Walberg, Amabile)
2. *Creative process*. The cognitive and social dynamics governing the creating ideas, expression and acceptance or adaptation of new ideas in the creative person, for example, searching, combining, and synthesizing (e.g., Graham Wallas, Rogers, Mackinnon, Hallman, Torrance, and Myers).
3. *Creative press (or environment)*. The influence of the ecological press on the person and upon his mental processes and

outcomes (e.g., Tardif and Sternberg, Csikszentmihalyi, Floistad, and Weisberg)

4. *Creative product*. Outcome or product being original, unique, valuable, and novel. The products of creativity can include behaviors, performances, ideas, things, and other kinds of output, through any channel or type of expression (e.g., Parnes, Taylor, Perkins, Torrance, and Johnson-Laird).

Criteria for Establishing Creativity

Shallcross states that the criteria for creativity are novelty or unusualness, appropriateness to the context in which it is placed, and transformation of materials or ideas that overcome conventional constraints. Johnson-Laird view that creative thinking must not be produced by recall from memory, rote computation, or any other simple deterministic process.

Gowan, Demos, and Torrance define human problem-solving as creative to the extent that one or more of the following conditions are satisfied:

1. If the product of the thinking has novelty and value either for the thinker or for his society.
2. If the thinking is unconventional, in the sense that it requires modification or rejection of previously accepted ideas.
3. If it requires high motivation and persistence, taking place either over a considerable span of time or at a high intensity.
4. If it deals with or solves a problem which, initially, as it was posed, was vague and ill-defined, so that part of the task of the creative thinker was to formulate the problem itself, to give it structure.

Torrance outlines criteria indicating a lack of novelty or a lack of invention: (1) changes requiring only mechanical skill; (2) change in size; (3) duplication of parts of a device; (4) omission of an element of a device or step of a method; (5) reversal of parts; (6) change of material; (7) use of an old process or method to a different but analogous object or material; (8) making a device adjustable; (9) change in an element of an old combination; and (10) aggregation of elements.

Moss, in examining the criterion problem, concluded that unusualness, usefulness, and combining unusualness and usefulness were the defining characteristics of the creative product produced by industrial arts students.

Murray and Stein opine that the criteria for establishing creativity are multidimensional and appear to depend not only on the end-product but also on the process involved.

Besemer and Treffinger reviewed the criteria of creativity set out in the literature (about 125) and developed a theoretical model, the creative product analysis matrix (or CPAM), which the creative product could be identified and measured in three general dimensions:

1. The novelty dimension: (a) germinal, (b) original, and (c) transformational.
2. The resolution dimension: (a) adequate, (b) appropriate, (c) logical, (d) useful, and (e) valuable.
3. Elaboration and synthesis dimension: (a) attractive, (b) complex, (c) elegant, (d) expressive, (e) organic, and (f) well-crafted.

Approaches to Creativity

Associationistic Approach to Creativity

Associative theory, as developed by Mednick defines the creative thinking process as “forming new combinations of associative elements which either meet specified requirements or are in some way useful.” Koestler’s bisociative theory claims that a creative act involves linking together two previously unconnected ‘frames of reference’ or ‘two separate entities’ (cf. Kohler’s theory of insight). Wallach and Kogan proposed that “creativity involves the ability to produce more associations and to produce more that are unique.” A similar view is asserted by Cartier that “there is only one way in which a person acquires a new idea: by the combination or association of two or more ideas he already has into a new juxtaposition in such a manner as to discover a relationship among them of which he was not previously aware. An idea is a fit of associations.”

Psychoanalytic Approach to Creativity

Psychoanalytic theorist Freud has emphasized the unconscious rather than the conscious. Creative activity is a form of daydreaming. According to Jung, creative people tend to suffer from emotional disturbances and are prone to be mentally ill. Freud argues that the creative process depends mainly on defence mechanisms, which are unconscious attempts to prevent the awareness of unpleasant or unacceptable ideas. The creative act is seen as transforming an unhealthy psychic state into a healthy one. Dacey intensify that an extreme position argues that “creativity is next to madness.” Kris, Kubie, and May state that though the source of creative thought may be unconscious, it is necessary for these thoughts to become conscious, otherwise they remain unrecognized and incommunicable.

Humanistic or Holistic Approach to Creativity

Humanistic psychologists feel that creativity develops throughout life and can be cultivated throughout the life span. They believe that humans, not divine, cosmic, or other forces determine their own fate. This is not to say that humanism is atheistic, but that self-reliance is a natural human trait. Rogers and Maslow take a holistic approach since they see the creative product as the result of an interaction between the creative person and his/her situation. Dacey states that “They see creativity as more conscious, cognitive and intentional than do the psychoanalysts.” The humanistic concept is that creativity is born through a striving for the highest possibilities in life, rather than as a defence against neurosis.

Gruber’s Piagetian Approach to Creativity

Gruber has analyzed Darwin’s evolutionary theory from a Piagetian point of view. He points to the long time periods involved in developing significant new ideas, emphasizes the slowness of changes according to Darwin’s system of ideas, and interprets the process of the changes in terms of Piagetian notions such as assimilation (incorporation of new information

into existing conceptual structures) and accommodation (changes in conceptual structure brought about by new information). Gruber argues that what appear to be dramatic breaks with the past, can be seen as the culmination of numerous small changes. This approach places ‘moments of insight’ within their long-term context and would suggest that little understanding of higher order creativity will result from laboratory studies of small-scale problem-solving. Gilhooly assumes that “If this approach is accepted, laboratory analysis of high level creativity would seem to be ruled out in favour of meticulous case studies.”

Information Processing Approach to Creativity

In the opinion of Gilhooly, the information processing approach takes the computer as its key metaphor for the mind, seeing people as computer-like systems that code, store, retrieve, and transform information. Information-processing technologists describe thinking as ‘dynamic processes.’ They equate the architecture of the brain with the computer and explain the process of thinking in terms of computer programming (algorithms and flowcharts).

Simon has indicated how the information processing approach might tackle the topic of creativity in science. Thinking is seen as a hierarchical organization of elementary process carried out one at a time. In a problem solving program, the solution efforts are guided and controlled by a hierarchy or ‘tree’ of goals and subgoals.

In a similar manner, Weisberg suggested that creative solutions develop as problem solvers acquire information indicating that their initial solutions were inadequate. In attempting to overcome these inadequacies, individuals try things they have not tried before. Finally, novel solutions to problems also arise in response to information that becomes available as the person works on the problem.

Boden’s Impossibility Theory to Creativity

Boden divides creativity into two categories: H-creativity (historical creativity) and P-creativity (psychological creativity). H-creativity refers to something that is created or discovered which no one has ever created or discovered before (e.g., Newton’s, Mozart’s, Picasso’s, Walt Whitman’s, Einstein’s), whereas P-creativity refers to something an individual creates or discovers, something they themselves have never done before, even though others may have done it before them. She notes that it is difficult to conclusively prove H-creativity, due to events such as the destruction of the great library at Alexandria.

An important aspect of either kind of creativity (‘H’ or ‘P’) is the ability to find new ways of looking at what is familiar and to find new connections between previously unrelated things.

1. Copernicus looked at the familiar sun in a new way and revolutionized astronomy.
2. Archimedes, in an inspired flash of insight, made the connection between his own body’s displacement of water in the bath, and the specific gravity of metals.
3. Kekulé discovered the ring structure of benzene while thinking about a ring of snakes chasing each others tails. He had actually seen such a ring some years before.

Computers and Creativity

According to Virtual Music Composer V3.0, the relationship between computers and creativity is a never ending story. And it will remain the same: things can always be better. And, we continue work on improving operating efficiency through new algorithms.

Essentially, there are two issues here. First, we need to define what creativity actually is. Second, we need to address whether this process can be done by a computer, or whether it is an inherently human ability. I have sidestepped this second issue by redefining the question slightly – can a computer do things that would be considered creative if a human did them?

Romeike explains that the term creativity is used with different meanings and is discussed controversially in psychology. Common speech usually defines something as creative when it comes from the arts or is something extraordinary. But not only artists can be creative. Everyday life requires creativity – and so does computer science. There is agreement in psychology that something is creative if it is new, original and useful.

Biggs reveals that the computer is a modeling machine, a language machine, and in this sense and by a stretch of the imagination, it is possible to conceive of a machine that in principle could model the human in sufficient detail to replicate the processes of creativity – if we accept a questionable concept of creativity founded on a linguistically heuristic system. Rather, it might be that the real value of the computer is not as a modeling machine, but as a metaphorical machine.

According to Margaret Boden, computers can generate novel ideas in all three ways, though they are best at modeling exploratory creativity. They can also aid human creativity.

Three types of creativity are:

1. Combinational creativity is the production of (valuable) unfamiliar permutations/combinations of familiar ideas.
2. Exploratory creativity involves exploring an unknown space, that is, a dimension or variable that has not been used before. Most professional artists and scientists engage only in exploratory creativity.
3. Transformational creativity involves thinking new thoughts which were previously impossible, with respect to the previous style of thinking. The conceptual space concerned must be transformed, by dropping/altering one or more of its dimensions. Then, new structures can arise which couldn't have arisen before.

Olson, in recognizing the importance of allowing students to create new products, stated:

Technology was born of creativity. . . . The creative imagination is the highest level of the intellect. . . . Emphasis on intellectual development, to think creatively, is the great imperative of industrial arts [technology education]. It draws out the individuality, discovers idiosyncrasy, establishes identity, and demonstrates potential, all essential to realization of self. . . . Designing with materials, tools, machines, energies, ideas is the way of technology and the way for industrial arts [technology education]. (p. 22)

Do Computers Think?

Do computers generate new ideas? Or help the people to think of new advertising slogans, write novels, or business plans, or think of new uses for things, or find a new way of doing things? Well, setting aside all these questions, we need to think how the people think about computers? As Sydney J. Harris, an American journalist, quoted: "The real danger is not that computers will begin to think like men, but that men will begin to think like computers."

Marvin Minsky views that most people think computers will never be able to think. That is, really think. Not now or ever. To be sure, most people also agree that computers can do many things that a person would have to be thinking to do. What the computer is doing is merely a superficial imitation of human intelligence. It has been designed to obey certain simple commands, and then it has been provided with programs composed of those commands. Because of this, the computer has to obey those commands, but without any idea of what's happening. Computers are good at storing information and retrieving this information. According to the manufacturers of Apple Macintosh computers the computers are also very good at manipulating information – sorting, selecting, and picking random items from lists.

The computer is not an especially visual machine. It has no special facility for imaging above that of other representational strategies. In a sense the computer is not a machine at all. It is a meta-machine, a control system for other machines. Biggs reveals that the computer can be employed with any machine or media, altering the manner in which it is organized and controlled.

In the opinion of Apple Macintosh computer manufacturers, the field of Artificial Intelligence (AI) is endeavoring to make computers emulate the human brain. AI may shed more light on how the brain works, but the view of using computers in thinking is that the computer is the tool and not the creator. The pioneers of AI see that computers might possibly go beyond arithmetic, and may imitate the processes that go on inside human brains. Marvin Minsky states that today, with robots everywhere in industry and movie films, most people think AI has gone much further than it has. Yet still, 'computer experts' say machines will never really think. If so, how could they be so smart, and yet so dumb?

AI indeed could solve problems that Frederick Brooks indicated as essential complexity in software development (source: softwarecreation.org):

- **Complexity:** computers could handle much more information than our individual brains, carry knowledge about all possible states of the system and effectively manipulate it.
- **Conformity:** computers could seamlessly conform to interfaces of the other system and support rules of interactions with brother computers.
- **Changeability:** computers will have full intellectual control over the system code and can quickly understand what should be modified and effectively support change requests.
- **Invisibility:** our brains are specialized on particular processing of information influenced by our biological origin. Computers don't have this problem and could naturally

manipulate information without need to visualize and limit scope for better comprehension.

Do Computers Think Creatively?

It is only natural to ask whether computers can think creatively. Many feel, in fact, that whereas computers can excel in well-structured areas of problem solving – for example, logic, algebra, etc. – they have little hope of ever producing truly creative work. For a work to be creative, it must be novel and useful – this represents an enormous challenge for artificial intelligence.

If creativity is the ability to produce different and varied solutions, which for computers is just a matter of seconds, the problem is that it has no idea what the solution means or implies. Butler views that “Many people would claim that a computer can never capture the essence of the mind because a computer could never, in and of itself, be creative.” Boden expresses that humans on the other hand, are creative in an aware fashion, prompted by heavy emotional baggage.

Computers are able to carry out well-defined tasks, but are of little use in solving the more vaguely defined problems common in research, or in the creative process generally. An ability to ask the right question is essential in doing innovative research. Computers can generate questions by drawing pre-defined questions from an existing database, but are unable to pose fundamentally new questions. The reason for this is that these machines can only carry out predefined numerical operations, whereas we do not have any algorithm that can translate our ability to ask exploratory questions into numerical operations. The over-intensive use of computers as a research tool may actually prevent us from posing the creative questions that drive innovation.

Do Computers Enhance Creativity or Destroy Creativity?

Creativity might be viewed as any process which results in a novel and useful product. People use computers for creative tasks; they flesh out ideas for text, graphics, engineering solutions, etc. Computer programming is an especially creative activity, but few tools for programming aid creativity. According to Selker, computers can be designed to foster creativity as well. In the opinion of Mills computers have traditionally been used as tools to raise efficiency. To realize the true value of computers, one should view them as tools to enhance human creativity.

As Hamza and Alhalabi state, technologies can be educators’ tools in finding creative ways that encourage students to self-test, self-question, and self-regulate learning in helping them to create solutions to complex problems. Application of ICT as a tool or medium for supporting or enhancing creative activity, and automation to attempts in artificial intelligence to replicate creative activity in machines.

Scragg et al. argue that computer science is a fundamentally creative endeavor. Students need to be encouraged to discover insights in the creative process of problem solving. Hill

describes open-ended problem solving and design processes in technology education as creative processes that engage exploration. She suggests moving away from making models to making prototypes for real-life contexts.

Computers are a wonderful interactive tool for making demonstrations. However, the danger is that the student only watches demonstrations without actively exploring the system that is simulated by the computer. Some researchers speculate that computer simulation technology may have a positive effect on creativity (e.g., Betz, Gokhale, Harkow). However, these researchers offer no empirical evidence to support their claim.

Some criticize computer use because computers – by their very nature are mechanistic and algorithmic – support only uncreative thinking and production. However, adults increasingly view computers as valuable tools of creative production. Educational research indicates that there is no single effect of the computer on creativity; technology can support either uncreative drill or creative production.

In the opinion of Eaglestone and Ford, it may at first sight appear that computers are irrelevant to creativity in that they are better at convergent than divergent information processing tasks, therefore having little if any role to play in supporting creative thinking.

Computers by their very nature are inherently algorithmic; and often the mechanical nature of algorithms is considered an anathema to creativity. As Bipin Indurkha questions, how can any creative insight result from following a predetermined set of instructions in a blind and seemingly mindless manner?

Clements states that computers have been found to be a fertile tool for supporting creativity. Many articles address IT supports for creative practice; however, there are just a few related to computer science education in schools. Research also provides strong evidence that certain computer environments, such as Logo, word processing, and design tools, hold the potential for the computer’s facilitation of creativity. There is equally strong evidence that the curriculum in which computer programs are embedded and the teacher who chooses, uses, and infuses these programs, are essential elements in realizing the full potential of technology.

As stated earlier, there are relatively few empirical studies on the effects of computers on creativity. The lack of research may be because instructional computing has only thrived over the last decade. The following are the few empirical studies found to date that address computers and creativity as measured by the creative product.

A study conducted by Joram, Woodruff, Bryson, and Lindsay found that average students produced their most creative work using word processors as compared to students using pencil and paper. Based on these results the researchers concluded that word-processing enhances the creative abilities of average writers. A reason for this result may be that word-processing helps average writers generate a number of ideas knowing that only a few of them will be usable and the rest can be easily erased.

However, the researchers also found that word-processing had a negative effect on the creativity of above average writers. These mixed results suggest that the use of word-processing may not be appropriate for all students. However, due to the

small number of subjects used in the study, results should be generalized with caution.

In a similar study conducted by Howe, two advanced classes in graphic design, consisting of 28 undergraduate students, were randomly assigned to one of two treatments. The first treatment group was instructed to use a computer graphic program to complete a design project whereas the other group was asked to use conventional graphic design methods to design their product. Howe concluded that computer graphics technology may enable graphic designers to generate an abundance of ideas, then capture the most creative ones and incorporate them into their designs. However, due to the small sample size and a lack of random assignment, results of the study should be generalized with caution.

However, an empirical study by Michael was to compare the effect of a computer simulation activity versus a hands-on activity on students' product creativity, originality, and usefulness. Fifty-eight middle-school technology education students from Northern Virginia participated in the study. Subjects were randomly assigned to either a computer simulation or hands-on treatment group. The computer simulation group used a Lego-type brick simulator to construct creative products on the computer; whereas, the hands-on treatment group used real LEGO® bricks to construct their creative products. The hands-on groups' products were collected by the researcher and copied into the computer simulation program. Both groups' products were printed using a color printer. The printed products were evaluated by expert judges using a creative product semantic differential scale. This study showed that there was no significant difference in product creativity scores among the computer simulation and the hands-on treatment group. The null hypothesis was accepted. Findings suggested that it was possible to use a computer simulation activity in place of a hands-on activity and still maintain product creativity, originality, and usefulness.

An exploratory study of Benedek et al., examined a computer-based divergent thinking training program with respect to its effectiveness in enhancing ideational fluency and originality on the basis of practice. Two training versions were developed: (a) a training of verbal creativity and (b) a training of functional creativity. Both training versions consisted of nine sessions with eight divergent thinking tasks each. Two training groups (consisting of 11 participants each) and a control group ($n=14$) were matched for creativity, intelligence, age, and gender; the groups were tested in a pre-posttest design. The findings point to the usefulness of a computer-based training to enhance creativity-relevant abilities.

Hinton combined the creative process and problem-solving process into what is now known as creative problem-solving. He believed that creativity would be better understood if placed within a problem solving structure. Creative problem solving is a subset of problem solving based on the assumption that not all problems require a creative solution. He surmised that when a problem is solved with a learned response, then no creativity has been expressed. However, when a simple problem is solved with an insightful response, then a small measure of creativity has been expressed, and when a complex problem is solved with a novel solution, then genuine creativity has occurred. Genuine creativity is the result of the creative process that manifests itself into a creative product. Understanding the

creative process plays an important role in enhancing the production of creative products produced within the technology classroom.

Scales and Snieder have the impression that computers often are a sink of valuable human time. Every computer system requires a certain amount of effort to make it operate. In addition, researchers often spend an inordinate amount of time tailoring their computer to their taste at a level of detail that is not required by the work that needs to be carried out. Of course, the investment of time up front in customization can pay long-term benefits in efficiencies, but it's easy to go overboard. The worries of using the computer can actually clutter the mind to such an extent that it makes creative thinking impossible. However, we also have the impression that present-day researchers might be much more creative if they would switch off their computer for one day per week.

Much like word processing and computer graphics technology, simulation technology is another type of computer application that allows users to freely manipulate and edit virtual objects. However, due to a lack of research, the true effect of simulation technology on creativity is still unknown and can only be surmised.

Summary and Conclusion

Computers are tools, not slave-masters, computers are inert, unresponsive, incapable of thought, but we can accomplish much through and with them. A computer can do a variety of tasks easily, which works under a set of instructions, automatically accepts the supplied data, processes and analyses the data, and produces the information.

Computer programming is an especially creative activity, but few tools for programming aid creativity. Computers can be designed to foster creativity as well. The steps of the creative process where software can be used include generating ideas, recording ideas, manipulating ideas, and implementing ideas. Many thinking techniques which are performed manually, maybe with pen and paper, can potentially be encapsulated in a program. The main benefits are the compact storage and ease of access.

The computer doesn't think; it can only execute the direction of a thinking person. If poor data of faulty programs are introduced into the computer, the data analysis will be meaningless. The expression *garbage in, garbage out* describes the problem quite well. It is critical when using canned programs to carefully follow the appropriate program syntax. If a comma or slash is missing, the program may stop processing the data, or worse yet, process the data incorrectly (e.g., Best and Kahn). Rather than knowing how to program a computer, most computer users simply need to understand how a computer functions, and what it can do. Even those who need to program a computer can do their job more effectively, with better understanding of how computers function, and their capabilities and limitations.

The computer is merely doing a superficial imitation of human intelligence. It has to obey the instructions encapsulated into the programs without knowing any idea of output. It is implicit that the computers are better at convergent (converges to one right answer) than divergent information processing

tasks, therefore having little if any role to play in supporting creative thinking.

Creativity cannot be derived in a logical way, in a step-by-step fashion. Computers by their very nature are inherently algorithmic; and often the mechanical nature of algorithms is considered an anathema to creativity. The reason for this is that these machines can only carry out predefined numerical operations, whereas we do not have any algorithm that can translate our ability to ask exploratory questions into numerical operations. The basic question as Bipin Indurkha posed was how can any creative insight result from following a predetermined set of instructions in a blind and seemingly mindless manner?

Creativity has different meanings, at different times, and in different contexts. Creativity is complex in nature. It is difficult to understand it by adopting one single definition. Different viewpoints have been put forward to explain the concept, emphasizing different aspects of creativity. Generally, creativity has been discussed in terms of its end product, the creative person, and also of the creative process and creative environments. There is agreement in psychology that something is creative if it is new, original, and useful. By and large, psychologists seem to agree that creativity involves the ability to produce original ideas and to perceive new relationships among unrelated things.

The associationistic theories emphasize that forming new combinations of associative elements which either meet specified requirements or are in some way useful or act involves linking together two previously unconnected 'frames of reference' or 'two separate entities.' Creativity involves the ability to produce more associations and to produce more that are unique. Psychoanalytic theorists have emphasized the unconscious rather than the conscious. The humanistic concept is that creativity is born through a striving for the highest possibilities in life, rather than as a defence against neurosis. Creativity develops throughout life and can be cultivated throughout the life span. Gruber points to the long time periods involved in developing significant new ideas.

P-creativity is more possible than H-creativity while working with computers, because P-creativity refers to when an individual creates or discovers something they themselves have never done before, even though other may have done it before them.

The most related approach to creativity is 'information processing' which takes the computer as its key metaphor for the mind, seeing people as computer-like systems that code, store, retrieve, and transforms information. They equate the architecture of the brain with the computer and explain the process of thinking in terms of computer programming (algorithms and flowcharts). Information-processing technologists describe thinking as 'dynamic processes.' Novel solutions to problems may arise in response to information that becomes available as the person works on the problem.

Creativity is the process of generating unique products by transformation of existing products. These products, tangible and intangible, must be unique only to the creator, and must meet the criteria of purpose and value established by the creator. In fact, creativity makes an object or activity better, richer, more productive, fruitful, and aesthetically satisfying.

As psychologists defined human problem solving as creative to the extent that one or more of the conditions are

satisfied. Creativity must not be produced by recall from memory, rote computation, change in size, aggregation of elements or changes in old combinations, duplication of parts of a device, or any other simple deterministic process.

According to McGuinness, computers are seen to be very smart, but they have no imagination. They can only slavishly follow instructions and rules – which means they can't think for themselves and generate original thoughts. What the computer is doing is merely a superficial imitation of human intelligence. It has been designed to obey certain simple commands, and then it has been provided with programs composed of those commands. Because of this, the computer has to obey those commands, but without any idea of what's happening.

Computers are good at storing information and retrieving this information. They are also very good at manipulating information – sorting, selecting, and picking random items from lists. Computers could handle much more information than our individual brains, carry knowledge about all possible states of the system, and effectively manipulate it. Our brains are specialized on particular processing of information influenced by our biological origin, whereas computers don't have this problem and could naturally manipulate information without need to visualize and limit scope for better comprehension.

For a creative work the product must be novel and useful. The ability to produce different and varied solutions, which for computers is just a matter of seconds has the problem that it has no idea what the solution means or implies. Computers can never capture the essence of the mind because a computer could never, in and of itself, be creative. However, humans on the other hand, are creative in an aware fashion, prompted by heavy emotional baggage, motivation, etc., and also the product of the thinking has novelty and value, either for the thinker or for his society.

Sally Bowman Alden identified six key areas that all children should be exposed to in using computers and software as tools – tools for learning, creativity, productivity, research, communications, and entertainment.

Except for a few educational researchers discussed earlier, there is no substantial research directly measuring the effect that the computer simulation technology can support either uncreative drill or creative production. Very few researchers speculate that computer simulation technology may have a positive effect on creativity.

Creativity, one of the hallmarks of the human spirit, has yet to travel deep into the domain of artificial intelligence and computers. As Bossomaier and Snyder opined that: "the major paradigm shifts of the future may be created by computers rather than people, in analogy with how acts of genius can arise from an autistic mind."

This article is a revision of the previous edition article by Kennon M Sheldon, volume 1, pp. 341–347, © 1999, Elsevier Inc.

Glossary

Acceptance Conformity that involves both acting and believing in accord with social pressure.

Compliance Conformity that involves publicly acting in accord with social pressure while privately disagreeing.

Conventionality Adherence to convention, or the normal ways people do things.

Ego-involved motivation In which action is prompted by an ulterior desire for social approval or a positive self-image.

Informational social influence Conformity that results from accepting evidence about reality provided by other people.

Interpersonal climate The sense of pressure versus freedom promoted when authority figures are controlling versus autonomy-supportive.

Normative social influence Conformity based on a person's desire to fulfill others' expectations, often to gain acceptance.

Reactance A motive to protect or restore one's sense of freedom in the face of normative influences.

Task-involved motivation In which action is prompted by an intrinsic interest in the task itself.

Defining Conformity

According to Merriam-Webster's on-line dictionary, conformity is "action in accordance with some specified standard or authority." As this definition implies, people may be powerfully influenced by social forces. Social influence can be *informational* or *normative*. Informational influence leads individuals to alter their behavior to accord with new knowledge obtained from others, whereas normative influence leads individuals to alter their behavior to accord with the conventional beliefs or practices of others. Informational social influence can aid the creative process, by enhancing a person's perception. For example, thoughtful criticisms of an artist's work from other members of a workshop may help to sharpen the artist's vision. In contrast normative social influence often works against creativity, in part by producing inaccurate perception. For example, Asch's classic studies in the 1950s showed that participants will agree with an incorrect group consensus regarding the length of presented line segments, ignoring the clear evidence of their own senses. Because it has received the most attention I will focus on normative conformity, and its potentially negative effects on creativity.

Another important distinction in the conformity literature is whether or not conformists actually believe the normative opinions that they espouse. Some individuals may be sufficiently lacking in self-confidence that they endorse a group's incorrect opinion both inwardly and outwardly. This form of conformity is termed *acceptance*. Research has made it clear that individuals who do this are unlikely to be creative. Other individuals may toe the party line in order to avoid making waves, while still maintaining a private, countervailing opinion. This form of conformity is termed *compliance*. The potential for individual creativity is more likely to be maintained in the compliance case, although by withholding their true thoughts from others, such 'expedient' conformers risk missing important feedback and information.

With more careful analysis the neat distinction between private acceptance and mere public compliance blurs. In most cases, normative influences concern more than simple perceptual judgments that have clear correct answers (e.g., the Asch line-length experiments). Group-level normative forces are most likely to play a role in the case of complex, many-sided issues, which have tangled ethical and doctrinal implications. Because of the ambiguity of many normatively informed issues, individuals may 'mistakenly' accept a prevailing opinion without realizing that it does not accord with their own prior inclinations or creative interests. Also, individuals may come to unwittingly accept a normative attitude that they originally merely complied with, because of self-perceptual or dissonance–reduction processes. In either case a danger is that over time people may lose, or fail to develop, the ability to discern their own values and interests. The inimical effects of such an occurrence are discussed below.

Another definitional issue concerns that of *conventionality*. This refers to the tendency to view or do things in the usual, socially accepted way. Conformity and conventionality are similar, but not necessarily the same; conformists may conform to conventions, but they may also defy conventions if the context establishes such defiance as normative. In contrast, a conventional person might conform to conventions in order to achieve social acceptance, but they may also do so out of habit or lack of imagination.

A final definitional issue concerns that of *reactance*. Those faced with strong normative pressure have a third option besides public compliance and private acceptance: they can resist, putting up a struggle against group norms. Although such counter-conformity can serve many useful functions, one danger is that the potential creator may become distracted by rebelliousness for its own sake. In other words, those who make a point of going against group opinion may, ultimately, be just as controlled by group processes and forces as those who passively go along with group opinion.

Why Conformity and Creativity 'Don't Mix'

Most commentators agree that there are powerful conflicts between creativity-related and conformity-related motives. Behavioral conformity typically involves a desire to be approved of by others, along with a corresponding fear of being rejected or ostracized by others. This desire is deeply rooted: given the importance of maintaining cohesive functioning within the small groups in which our ancestors lived, there is good reason to believe that evolutionary pressures selected for a strong motive to be approved of by 'the group.' Peoples' fears of being rejected by social groups if they do not conform are often justified – many experiments have demonstrated that those who persistently flout normative opinion are punished by, and finally excluded from, the groups of which they are a part. Interestingly, such results suggest that humans, besides having a built-in (or evolved) motive to seek approval by groups, also have a built-in motive to 'stifle' those who challenge the status quo of their social groups. This tendency to resist others' *non*-conformity is also likely to be antithetical to creative accomplishment, insofar as it prevents individuals from thinking about the new ideas or possibilities suggested by others.

In an influential early (1962) chapter, Richard Crutchfield described conformist motivation as *ego-involved*. Conformists are strongly focused on how they are perceived by other group members, and their primary goal is to protect or enhance their self-image and self-esteem. In contrast, creative performance tends to require strong *task-involvement* – that is, an exclusive focus on the problem at hand, in combination with a desire to get to the bottom of things no matter where the search leads. Unfortunately, the 'search' may often lead in directions which contradict or upset established beliefs, practices, or bureaucracies. In order to develop and market their new ideas individuals must often be willing to diverge strongly from group norms and accepted behavior, risking alienation and potentially drawing the group's wrath. Thus, one way in which conformist pressures may inhibit creativity is by reducing a person's willingness to follow through with a new idea or course of action. This may occur to the extent that a person's task-involved motivation is overwhelmed by his or her approval motivation.

A second potential negative effect of conformist pressures, alluded to above, is that they may cause people to lose touch with their own perceptions and thought processes. Creative activity depends on individuals' ability to access, and engage in open dialog with, their own experience. Very often the first glimmerings of a new idea or approach are subtle and evanescent, at the 'fringes' of consciousness. To the extent that individuals rely on others for guidance on how to think and behave, they may lose the ability to recognize and grasp such glimmerings within themselves. For example, one important first step in the creative process involves explicitly recognizing that there is a problem to be solved. Group mentalities are notoriously resistant to such recognition (i.e., when John F. Kennedy's 'group-thinking' advisors did not perceive the obvious flaws in the Bay of Pigs plan). Those who are over-invested in group approval may fail to notice their own nagging doubts or reservations regarding a course of action, or fail to recognize the seeds of a promising new idea when it occurs to them.

Thus far in this entry, the negative effects of conformity upon creativity have come about because group minds tend to resist or discourage innovation. However, it is also possible for negative effects to occur even when groups openly *welcome* creativity. For example, art professors may encourage students to compose works which are unusual and original, and students may receive many kinds of social rewards for succeeding in this aim. However, research by Amabile and colleagues indicates that creative functioning can be impaired to the extent that people become explicitly oriented towards such extrinsic rewards. Specifically, reward- or approval-oriented motivation has been associated with less cognitive flexibility, more shallow processing of new information, less integration of new information with preexisting knowledge, and less creativity in general. These decrements occur in part because thoughts of reward may intrude into actors' minds, distracting them and dividing their attention. In contrast those who can remain intrinsically or task-motivated are more likely to maintain access to their own deeper cognitive resources, and thus are more likely to be creative. Readers should know, however, that the question of whether rewards have detrimental effects upon creativity remains controversial, as Eisenberger and Cameron have shown that rewards can facilitate creativity under certain conditions, and even Amabile has suggested that in some cases of entrepreneurship, extrinsic motivation can have 'synergistic' positive effects in combination with intrinsic motivation.

To summarize, excessive concern for group norms and opinions is likely to inhibit a host of motivational, cognitive and self-regulatory processes essential to innovation. Such concerns may reduce the *quantity* of one's motivation to pursue an innovative line of thinking, as when one fears rejection by the group; or, such concerns may detract from the *quality* of one's efforts, when they involve excessive focus on receiving anticipated social rewards or avoiding anticipated punishments. It is worth noting at this juncture, however, that social groups need not *necessarily* pull for conformity. Some research suggests that group processes can even enhance individual creativity, such as group brainstorming techniques, or corporate climates which intentionally focus on change and encourage unconditional respect for each group-member's creative efforts (see Paulus and Brown's 2003 review of the group brainstorming and creativity literature). However, ego-involved motivations easily emerge even in the most egalitarian of social contexts, perhaps explaining why group contexts have a negative effect upon creativity, on the whole.

Conformist Forces Within Situations

Research on the contextual determinants of creativity has focused on the impact of authority figures upon creative performance. In 1995, Sternberg and Lubart noted a variety of perplexities in this literature. For example, some research suggests that creativity is *enhanced* when authorities set limits, explicitly structure the task, set up competitions, spell out criteria for evaluation, and render judgment upon individuals' performance. However, other research indicates that external constraints, competition, and evaluation pressures all *detract* from creativity. Sternberg and Lubart suggested that these contradictory research findings are in part due to differences in the

difficulty of the creative tasks employed in different studies, differences in subjects' prior experience with the tasks, or differences in subjects' initial arousal levels.

In addition to these possibilities, an important general factor determining when external constraints are detrimental may be the *interpersonal climate* in which they are administered. The theories of Amabile, Deci, and Ryan suggest that whenever constraints are viewed as controlling, they will tend to reduce task-motivation and hence creativity. Presumably this is because a controlling authority's demeanor induces reactance or approval motives, or leads individuals to become overly focused on extrinsic rewards or punishments. As noted above, any of these foci can drain away cognitive and self-regulatory resources. In contrast if evaluations and constraints can be delivered in a noncontrolling, information way, helping to better define the task while still supporting personal autonomy, an optimal context for intrinsic motivation and creativity may result.

Much research, conducted in both educational and work environments, is consistent with this conclusion. For example, teachers who conduct classes informally, welcome unorthodox views, and allow students to choose what to investigate, and treat students as individuals, are most likely to produce creative students. Similarly, 'open' classrooms, in which students are allowed considerable flexibility and individualized effort is encouraged, tend to produce more creative students than do traditional classrooms which rely on drill, large group instruction, carefully prepared curricula, and which emphasize exams and grading. Paralleling these findings, Amabile has identified manager characteristics conducive to creativity. Managers who set challenging goals and then grant employees substantial freedom and control over their work, who are not overly strict and who can evaluate work nonthreateningly, and who encourage new ideas, are most likely to engender creative performance in their subordinates. In contrast, organizations in which there is defensiveness, a lack of freedom, and an unwillingness to risk change, do not function as creatively; in such contexts, conformity and rigidity are likely to 'rule the day.'

Normative forces work not only at the level of the group, classroom, or organization. Increasing attention is being given to *cultural* differences in conformity, and the effects of such differences upon the creativity of citizens within various cultures. For example, recent research has examined aspects of Japanese, Chinese, Turkish, Senegalese, Hong Kong, Sudanese, Iranian, and Israeli culture which may predispose citizens of those societies towards greater conventionality and reduced creativity. Kaufman and Sternberg's 2006 *Handbook of International Creativity* contains more information on these issues.

Conformist Forces Imported into Personality

Besides studying social contexts which increase conformity and thus detract from creativity, researchers have also studied personality traits and styles related to conformity. In other words, conformity can be an enduring state of mind, not just a product of momentary situational influences. Such personality styles may develop when a child's efforts at independent self-expression are repeatedly punished or discouraged by parents or peers, or when love and affection are given only when the child conforms to rigid rules and regulations. This treatment may

create an abiding insecurity and anxiousness regarding the approval of others, crippling the growing person's ability to be creative (although some have argued that early experiences of alienation can catalyze the formation of powerful creative personalities). Sulloway's 1996 work indicates that birth order may also influence the acquisition of conformist traits. First-borns, being more naturally aligned with parents, are more likely to uphold the status quo. Although they tend to become high career achievers, they do so through relatively low-risk ventures and tend to resist important innovations in their fields. In contrast later-borns, having less power and receiving less attention, may be 'born to rebel' against the familial status quo. Later, they may be more likely to make innovative contributions to their fields, and quicker to recognize and support legitimate paradigm shifts within their fields.

Little research has directly studied the relation of conformist traits to creativity. Instead, research has focused on the opposite pole, personal *autonomy*, considered one of the 'core characteristics' of the creative personality. Autonomy refers to the preference for regulating oneself, instead of being regulated or controlled by social forces. Related personality traits include Independence of Judgment, Self-Directedness and Self-Determination, Self-Sufficiency, Self-Assertiveness, and Individuation. Such traits have been repeatedly shown to predict both momentary and lifetime creativity. This is because those high on these dimensions tend to (a) show less suggestibility and less need for the approval of others; (b) more courage and persistence in the face of criticism and pressure from others, and more willingness to express dissenting opinions; (c) more ability to maintain their task-involved or intrinsic motivation, and less susceptibility to ego-involved or performance motivation; and (d) more ability to maintain contact with and behave on the basis of enduring personal feelings and attitudes, rather than responding in a chameleon-like manner to momentary contingencies and norms. Although most of the above findings are correlational, some experimental work has been conducted. For example, Crutchfield and his associates demonstrated in the late 1950s that those high in autonomy-related traits are much less likely to conform to the (incorrect) group opinion in the Asch line-length paradigm, compared to those low in such traits.

One way of explaining the autonomy-creativity relationship is to posit that autonomous individuals are more inclined to perceive potentially controlling social environments primarily in informational terms. This could give them at least two extra resources in their creative efforts. First, because they are not heavily dependent upon others' approval, autonomous persons may be better able to take what is useful from the comments and opinions of their peers, while rejecting and discarding that which is not useful. That is, their autonomy may 'inoculate' them against the danger of losing touch with their own perceptions as they make contact with others' ideas. Second, the ability to perceive potentially controlling events in informational terms is likely to help individuals to maintain their intrinsic or task-focused motivation, and thus maintain full access to cognitive resources. Individuals do in fact differ in the ability to shrug off potentially coercive input. For example, Deci and Ryan reported that women are more likely to interpret ambiguous social feedback as controlling, detracting from their intrinsic motivation and perhaps creativity.

Another way of understanding the relationship between personal autonomy and creativity is in terms of an 'evolving systems' model. Gruber's psycho-biographical studies revealed that important new themes and realizations tend to emerge slowly within the work of notable innovators, rather than occurring in moments of sudden insight. For example, although the first inklings of the theory of evolution appear in Charles Darwin's notebooks early on, the model matured slowly and required much of Darwin's life span to be worked out fully. This indicates that lifelong persistence and dedication to self-posed and self-defined problems may be crucial for the development of extraordinary creativity. Such long-term task-involved motivation is unlikely to be manifested in those who are easily swayed by popular opinions of the moment, and who take the cue for their work from current fads and trends.

A related perspective concerns the progression of an organismic integration process, occurring in a deeper way or at a faster rate within notable creators. Sheldon proposed an 'attunement' hypothesis, in which autonomous persons are in better touch with the inner organizational tendencies that are inherent in developing life. Although such integrative tendencies are natural they are also fragile, and may be forestalled to the extent that the person cannot detect his or her own authentic reactions amidst the din of social influence. Creative accomplishment may thus be viewed as a mere side effect of a more general integration process, which occurs automatically to the extent that people are fully 'in touch' with themselves. This understanding of creativity is similar to that advocated by Maslow and Rogers, with their concepts of self-actualizing or fully functioning persons.

Creative Personality Development as the Overcoming of Conformist Tendencies

As suggested by the above, a number of theories posit that exceptional creativity occurs only after would-be creators have succeeded in psychologically differentiating themselves 'from the crowd.' Most prominent among these is the psychodynamic model of Otto Rank, published in 1932. Rank proposed three *types* or *stages* of personality: a *conformist*, adapted type who takes their cues from those around them; a *conflicted* type, who has broken free of norms, but is confused and unhappy; and a *creative* type, who has gone through both of the latter stages, to emerge with a powerful creative voice of their own.

A substantial body of research supports Rank's conception. For example, MacKinnon used the typological model to characterize the three groups of architects examined in the well-known IPAR studies. The nationally renowned creative architects in this sample were a good fit to Rank's 'creative' prototype; the less renowned associates of these architects fit the 'conflicted' prototype; and a control group of ordinary architects fits the adapted or 'conformist' prototype. Consistent with Rank's developmental assumptions, notable innovators often report an early sensitivity to controlling influences, which results in early rebellion against the *status quo*. For example, Hammer, in his extensive 1984 study of adolescent artists, found that the most gifted among them were experiencing profound conflict and emotional turmoil, and were also engaged in a retreat from their peers. These efforts at

detachment were motivated by an attempt to "resist the corroding effects of over-conformity." Similarly, Getzels and Jackson's comparisons of highly creative and highly intelligent youths in the early 1960s showed that creative youths were more mocking of conventional aspirations and beliefs, and were much less popular with their teachers, despite the fact that their level of academic achievement was no less than the high IQ group.

Creative individuals may begin to resist conventional thinking at a relatively early age, in response to particular developmental crises or environments. For example, in 1966 Torrance identified a 'fourth grade slump' in creativity, driven by children's increasing sensitivity to peer opinion at this age. A young child's ability to stand up to such early conformist pressures may represent a significant developmental achievement, and may serve as an important predictor of later creative achievement by that person. To be creative, one must sometimes 'defy the crowd' – perhaps the sooner this occurs, the better. As noted above, however, those seduced into pursuing nonconformity for its own sake, rather than as a way of gaining the freedom to work, may yet be slaves to group opinion.

Recent Priming and Small Group Research Relevant to Creativity and Conformity

Now, we return to the domain of 'conformist forces in situations,' focusing on subtle cognitive influences rather than interpersonal influences. In the last ten years, new methodologies have been developed for studying situational priming effects upon behavior. Several experimental studies with college students have shown that creative performance can be influenced by both conscious and nonconscious conformity-relevant priming manipulations. For example, Wiekens and colleagues showed that priming 'I' produced more divergent thinking than priming 'We'; Galinsky and colleagues showed that priming social power in participants through relevant semantic primes, autobiographical memories of power, or role manipulations of power, produced greater creative production, compared to participants in a control group; and Forster and colleagues showed that priming 'deviancy' or 'punk' produced more creative thinking compared to a control group. All of these studies indicate that creative performance can be enhanced when participants are cognitively primed with concepts that counteract or mitigate against conformity pressures. In other words, although people may automatically tend to follow the crowd and think inside the box, in some cases, the social or informational environment can work to *reduce* these unfortunate tendencies, rather than increase them (as was described earlier). Teachers, coaches, and leaders would do well to keep this in mind; 'the power of the situation' can be positive as well as negative.

In addition, the last ten years has seen an increase in studies of group creativity and problem-solving. What allows groups (not just individuals) to be most creative? Once again, results support the notion that situational influences can sometimes enhance, rather than detract from, creativity. Nemeth and colleagues found that allowing or encouraging dissent or conflict within groups promotes improved creative group cognition; Paulus and colleagues concluded that although greater group

diversity produces more conflict and frustration at first, later group creativity is enhanced; De Dreu and colleagues demonstrated that higher levels of minority dissent within groups predicted greater creative performance by groups as a whole; and Jung and colleagues showed that transformational (inspirational) leadership produced more group creativity than transactional (directive) leadership styles. This research is similar to research examining factors which prevent 'group-think,' but focuses on enhancing creativity as the outcome, rather than preventing premature or myopic group decision-making as the outcome.

Conclusion

In this entry I discussed both situational (priming, group context, reward structure, leader communication style) and personal (dispositional, motivational, and developmental) factors that influence conformity and creativity. The research suggests a variety of approaches that authorities and leaders can take in trying to maximize the creativity of their subordinates, and also suggests a variety of attitudes and approaches that subordinates can take to protect their creative abilities when leaders and groups fail to support them. Obviously, creativity is multiply determined, and there will always be exceptions to the 'rules' I have put forth – as when a highly controlled individual finally 'busts loose' from confining restrictions, producing a creative product that would not have happened without those restrictions; or when a conventionally oriented individual discovers their creative side only after an external incentive is provided to reward creative solutions. Still, in order to maximize creativity

on average, it is probably a good idea to design social environments and personal attitudes in the ways suggested by this review of the research. Authorities should support the autonomy and personal power of subordinates; should de-emphasize norms, conventions and rewards, at least during idea generation phases; and should be sensitive to developmental processes within subordinates that may lead to creative breakthroughs. Creativity by definition involves going beyond the norm and the known, and is very difficult to achieve if the norm and the known dominate the individual's thinking.

Glossary

Confucianism An intellectual and spiritual tradition based on Confucius' teachings that emphasize self-cultivation through effortful learning and the attainment of social harmony through virtuous and beneficent rule by the government.

Li (1) The Confucian notion of proper behavior. It refers to propriety (the right thing to do) as well as to the proper rites or ritual. (2) Reason or principle. It is the central construct in the study of Confucianism by Chinese scholars in the Song and Ming dynasties. (In written Chinese, these words are written with different characters.)

Ren The most important and supreme Confucian virtue. It is often translated as humanness, goodness, or benevolence, but can be better understood as the respect for and love of humanity.

Ru The Chinese word for Confucianism. It may refer in different contexts to the Confucian school of thought as in *ru-jia*, the Confucian religious tradition as in *ru-jiao*, or the study of Confucian classics as in *ru-xue*.

Xiao The Confucian emphasis on respect and love for one's parents and elder relatives. It is often translated as filial piety, and is the cornerstone of family and social order.

Introduction: Confucius and Confucianism

Throughout history, Confucianism has been one of the most influential systems of thought in China. It has continued to evolve during the past three millennia, and represents an integral and important part of Chinese civilization. Over the years, its influence has extended far beyond the borders of China, into Korea, Japan, Vietnam, and large parts of Southeast Asia, and more recently, into Europe and North America. The extensiveness of its influence can be attributed to the comprehensive system of ideas and beliefs that provides not only a philosophy of life for many millions of people but also a guiding ideology for some states, including the Chinese empire in pre-modern China and the governments of modern Singapore and South Korea.

Given that Confucianism is a major intellectual and spiritual tradition in the world, it is natural to ask whether Confucianism offers a distinct way of looking at creativity, and whether Confucianism values and encourages creativity. Interestingly, there is no exact word equivalent to creativity in Chinese. Yet, Confucianism has often been looked upon by scholars as a system of thought that goes against novelty and creativity. It is therefore somewhat puzzling to find that China as the country where Confucianism has its roots has a history of flourishing art and invention. To understand this paradox, the basic ideas of Confucianism will be introduced in this entry. We will first discuss the multiple meanings of Confucianism, the life and work of its founder, and the evolutionary history of Confucianism, to set the stage for understanding the importance of studying the Confucian texts as a path to self-cultivation and enlightenment, which could be interpretable as the wellspring of creativity. We will then explore why Confucianism has often been regarded as a conservative force against creativity. Finally, we will turn to the consideration of how Confucianism could be interpreted to inform our understanding of novelty and creativity from the Chinese perspective.

The Multiple Meanings of Confucianism

Even for Chinese scholars, Confucianism has multiple meanings. Confucianism (or *ru* in Chinese) may refer to *ru-jia* (Confucian school of thought or approach), *ru-jiao* (also *kong-jiao*; Confucian cult or religious tradition) or *ru-xue* (studies of Confucian classics and their annotations and commentaries). Tracing the original use of *ru* from different sources, scholars have found that *ru* was used to refer at different times to specific groups of people who were dancers and musicians in religious ritual, or who were masters of ritual and ceremonies, or who were teachers or trainers of dancers, musicians, and performers in ritual, rites, and ceremonies. Subsequently, *ru* was gradually extended to refer to specialists or experts with skills of ritual, history, poetry, music, mathematics, and archery. By the time of the Warring States period in Chinese history, Confucius, whose name gives rise to the naming of Confucianism, was recognized as the best representative in the *ru* tradition. Thus, *ru* came to be identified with the teachings or doctrines propagated by Confucius.

Confucius: His Life and Work

Confucius (551–479 BCE) is the Latinized form of Kong Zi (also Kong Fuzi; Master Kong) whose real name was Kong Qiu or Kong Zhongni (Figure 1). He was born in Qufu in the small state of Lu (in present-day Shandong province in Eastern China), and lived in the Spring and Autumn period of the Zhou dynasty. Although he was a descendant of aristocrats from the royal house of the Shang dynasty, he was brought up in poverty. It was said that his family declined and his grandparents were forced to migrate from the state of Song to the state of Lu. His family suffered further decline as his father died when he was three years old, and he was raised and educated by his mother. As a young man, he witnessed the downfall of the Zhou dynasty and the resulting social disorder and military conflicts among the many feudal states. Along with many thinkers from different schools of thought at the

Figure 1 The Statue of Confucius at New Asia College of the Chinese University of Hong Kong, Hong Kong.

time, Confucius attempted to provide an explanation for the social chaos and sought to put forth his ideas to the ruling autocrats for restoring social order and harmony. He believed that social disorder was developed from the misuse and abuse of *li* (ritual/propriety) and *yue* (music), and the restoring of social harmony required the ruler to govern by virtue, starting with the appropriate use of ritual and music, which reflected the cultivation of moral excellence on the part of the ruler.

Despite his vision of transforming government and restoring social order, Confucius held office for only a few years at Lu. His first important appointment was as magistrate of the district Zhongdu (501 BCE). Because of his successful administration, he was promoted to Minister for Construction (500 BCE) and Chief Justice, and he possibly served as acting Prime Minister for a short period (499 BCE). Realizing the difficulty in putting his ideas into practice in Lu, he left his home state and started his 13-year tour to different states, trying in vain to convince rulers of these states to adopt his ideas in governing and in social reform. With a change of the political climate at Lu, Confucius returned home, dedicating the rest of his life to teaching students and editing ancient classics. He died at the age of 73, and it was said that even the Duke Ai of Lu came to express his condolences. He was hailed as the Supreme Sage by historian Sima Qian who wrote his biography in the Han dynasty. However, as a sage and a great teacher, Confucius has left behind very few written works. The most important source of knowledge of his ideas and teachings

is *Lunyu* (*The Analects*), which is a compilation of conversations between Confucius and his disciples and other people.

It was said that Confucius had 3000 students, among whom 72 were more well-known disciples. After the bereavement period of three years (six years for his favorite disciple Zigong), his disciples and students went afar to different states to spread his teachings, either acting as administrators of states or as teachers who set up schools to teach the principles of the *ru* tradition. Gradually, *ru* became a name attached to a scholar who followed the footsteps of Confucius to teach and interpret the classics, and to engage himself in administration, education, and the preservation of ancient ritual and music. Since followers of Confucius might develop different understandings and interpretations of the master's ideas and teachings due to the multidimensional themes in the master's conversations in *Lunyu*, different sub-schools of *ru* emerged with slightly different methods of learning and practice, all considering themselves to be faithful followers of Confucius and his school of thought or *ru-jia*. A brief description of the evolution or development of Confucianism may be helpful for us to understand the emergence of the different sub-schools in *ru-jia*, and their possibly different views on creativity.

Brief History and Development of Confucianism

While Confucianism was named after Confucius, the core of Confucian thought can be said to go back to the time before Confucius, possibly to 1100 BCE after the Zhou people had conquered the Shang people. Confucius also talked about himself as a transmitter rather than a creator of the *ru* tradition. He believed that he was merely teaching the *Dao* (The Way) of the ancient legendary sage-kings, the three sovereigns (Fu Xi, Shen Nong, and Huang Di) and the five emperors (Yao, Shun, Yu, King Tang of Shang, and King Wu of Zhou). He further believed that these sage-kings had *de* (virtues) and therefore *tianming* (the Mandate of Heaven) to rule. Therefore, the mission of Confucianism or Confucian teachings was aimed at promoting the self-cultivation of virtues and the revival of the ethics of the early Zhou dynasty to restore social harmony. After the death of Confucius, Confucianism was spread by his followers, giving new characteristics to the Confucian doctrines, with an enriched content of Confucian practices and a broadened range of interpretations of Confucian teachings. Taken together, it is no surprise that Confucianism tends to regard nothing as novel, and it would be appropriate to attribute novelty to the results of a revival or continuation of what happened in the past.

Scholars examining the history of Confucianism tended to classify the development of Confucianism into stages. One simple, perhaps oversimplified, classification is to divide the development of Confucianism into a formative or creative stage characterized by the enriched elaborations of Confucian teachings by different philosophers before Confucianism became the state ideology in the Han dynasty, as opposed to the interpretative stage characterized by the emergence of different interpretations of Confucian teachings in a period of classical learning after the Han dynasty.

Perhaps, a more useful classification is one that expands the two-stage approach into a three-epoch approach with

sub-stages or transition periods to take into account the interplay between Confucianism and the many other traditions that also existed through the long history and development of Confucianism. The three epochs are the Pre-Qin *Ru-xue*, the Song-Ming *Ru-xue*, and the Modern New Confucianism.

Pre-Qin *Ru-xue*

The first epoch is the period of the *Ru-xue* of the Pre-Qin Scholars. This is the formative stage in which Confucianism took shape with the teachings of Confucius based on the teachings of the pre-Qin scholars during the Spring and Autumn period (770–476 BCE), through the modification, elaboration, and clarification by scholars such as Meng Zi and Xun Zi in the Warring States period (475–221 BCE), to the time of Dong Zhongshu in the Han dynasty when Confucianism was first declared the mainstream and state ideology.

A marked transition period between this first epoch and the second epoch was the reformation and revival of Confucianism in the interaction between Confucian schools and the schools of Legalism, Yin-Yang and the Five Elements (metaphysical forces), Moism (the teachings of Mo Zi) and Daoism (the teachings of Lao Zi and Zhuang Zi). This took place mainly in the Han dynasty when Confucianism recovered gradually from the setbacks under the Qin persecution and the Legalist discrimination. The revival was characterized by a more established theological and metaphysical doctrine of interaction between Heaven and human beings. The continuing debates on the interpretations of the Confucian classics inevitably led to a period of emphasis on the scholastic studies of words and sentences in the classics, which in turn led to further new developments in the second epoch. In a broad sense, this period lays the foundation for the notion that what is old encompasses what is new, and novelty emerges from the old only through active human efforts.

Song-Ming *Ru-xue*

The second epoch is the period of the Song-Ming Study on Principle (*Song-Ming Lixue*; *li* meaning principle as distinguished from the homonym *li* meaning ritual). Confucianism at this epoch is also known to Western scholars as Neo-Confucianism. In this epoch, Confucianism was faced with challenges from Buddhism and Daoism. Inspired by Buddhist philosophy and Daoist spirituality, Confucian scholars started to reformulate the Confucian view of the universe, society and the self, while at the same time removing elements that they considered to be Buddhist–Daoist superstitions from Confucian doctrines. Indeed, Confucian concerns were expanded to include metaphysics and new methods for self-cultivation and enlightenment. Consequently, a comprehensive system of new emphasis in Confucian learning called *Lixue* (the Learning of the Principle/Reason), or *Daoxue* (the Learning of the Way) emerged from this movement. Notable scholars of this epoch were Zhu Xi and Wang Yangming, and the two advocated somewhat different approaches. This period is marked by the initiation of the belief that, in addition to effortful learning, self-reflection or meditation is a path to achieve enlightenment, which could be the wellspring of creative work.

Although historical records suggested that Confucian doctrines and institutions were introduced to Vietnam, Korea, and Japan as early as the Han dynasty, it was in this epoch that Confucianism was introduced more formally to these East Asian countries, and appeared as new forms of presentation after integrating with local cultures and traditions to satisfy the social and political needs of their own countries. This epoch ended with the decline of the dominance of Confucianism in China and East Asia, corresponding roughly to the beginning of the twentieth century.

Modern New Confucianism or *Xiandai Xin Ru-xue*

The third epoch started to take place in the twentieth century, marked by the critical reflection on traditional doctrines initiated in the May 4th Movement (CE 1919). With the influence of Western thought, modern Confucian scholars started to reinterpret Confucian doctrines in the light of Western traditions and other world philosophies, especially European philosophical traditions and Christian spirituality in the modern age. Singapore (under Lee Kuan Yew) and Taiwan have looked to the ideas of Confucianism as crucial in morality and social harmony. In recent decades, Confucianism has also been identified as a vital part contributing to the booming economies of East Asian countries before the onset of the more recent worldwide financial turmoil, despite the claim that Confucianism is an obstacle to innovation and China's modernization. Contemporary scholars, including Mou Tsung-san, Carsun Chang, and Tu Weiming, have contributed to the revival of Confucian values and the transformation of Confucian doctrines, and they have named this rejuvenated Confucianism *Xiandai Xin Ru-xue* (Modern New Confucianism).

The Confucian Texts: The Five Classics and the Four Books

Despite the fact that Confucianism has undergone evolutionary changes throughout the years, a number of Confucian texts remain at the heart of the Confucian tradition. These texts are generally referred to as the Five Classics (*Wu Jing*) and the Four Books (*Si Shu*). It is believed that immersion in the study of these texts provides the path to self-cultivation, and therefore enlightenment.

The Five Classics

The recordings of the culture and wisdom of the sage-kings of antiquity, once edited and interpreted, became known as *Jing* or a classic. There are five of these texts: *Shijing* (*The Classic of Poetry*), *Shujing* (*The Classic of Documents* or *The Classic of History*), *Yijing* (also *I Ching*; *The Classic of Changes*), *Liji* (*The Record of Rites*), and *Chunqiu* (*The Spring and Autumn Annals*). Traditionally, Confucius was credited with writing *Chunqiu* as well as the *Shiyi* (*Ten Wings*), the commentaries on *Yijing* or *Zhouyi* (*The Yi of Zhou*), and with editing the four other classic texts. There was also a sixth text, the *Yuejing* (*The Classic of Music*), which was lost before the third century BCE. Each of the texts is said to capture an important component of ancient wisdom. Therefore, for Confucian scholars, ancient

wisdom could be made accessible through the study of these texts for the promotion of social harmony and order, and for the provision of the means to self-cultivation and becoming fully human. Accordingly, the Five Classics (*Wu Jing*) could be viewed as five perspectives or lenses in understanding the Confucian tradition.

Shijing is a collection of 305 poems ranging from court hymns to folk songs. This classic provides the poetic lens of the Confucian valuation of common human feelings. The verses generally represent emotions and sentiments of people from all walks of life expressed on different occasions. Many of the poems could be read as allegorical commentaries on the community and the government.

Shujing is a record of historical events and political treatises, dating to the time of China's remote past with legendary sage-kings and the three dynasties (the Xia, the Shang, and the Zhou). By referring, for example, to the time of Yao, Shun, and Yu, whose sagacity, filial piety, and dedication to work enabled them to rule on the basis of responsibility and trust by the people, this classic provides the political lens on the Confucian vision on moral behaviors and good government.

Yijing consists of a handbook of divination (*Zhouyi*) and the commentaries (*Shiyi* or the *Ten Wings*). The commentaries are believed to have been added by Confucius or Qin-Han scholars to help decipher the abstruse and opaque judgments of the text. This classic provides the metaphysical lens, as it not only captures the ancient practice and theory of divination but also underscores the intimate connection between the human and the natural realms. The system of divination is based on 64 hexagrams representing various combinations of the two interacting and vital forces of *yin* and *yang*. It was believed that the hexagrams and their transformations represented all possible conditions and scenarios in the constantly changing world, making it possible to seek guidance from Heaven.

Liji is a collection of materials that include comprehensive discourses on ritual, rites and learning, interpretations of ancient rites, recordings of the sayings and affairs attributed to Confucius and his disciples, ancient ritual or ceremonies, and ancient proverbs, maxims and aphorisms. It provides the social lens on society as a community of trust with emphasis on communication and appropriate behaviors, and articulates the basis of Confucian self-cultivation.

Chunqiu records political, economic, natural, and diplomatic events for a period of 242 years from 722 BCE to 481 BCE. It follows the chronicle of events in the state of Lu, the home state of Confucius. The annals could be read for moral judgments and guidance for rulers, providing the historical lens that reanimating the old could be regarded as the best way to attain the new.

The Four Books

From the Han and the Tang dynasties, the Five Classics were the key texts for Confucian teachings and for state examination. In subsequent years, other texts, including *Lunyu* (*The Analects*), *Mengzi* (*Mencius*), and *Xiaojing* (*The Book of Filial Piety*), were added to augment the teachings of the Five Classics, with a total of 13 texts identified by the ninth century CE.

In the Song dynasty, Zhu Xi took on the task of integrating different presentations of Confucian teachings by singling out four texts that he believed could represent the core of Confucian canon. Since then, they have been known as the Four Books (*Si Shu*): *Daxue* (*The Book of Great Learning*), *Zhongyong* (*The Doctrine of the Mean*), *Lunyu* (*The Analects*), and *Mengzi* (*Mencius*). Both *Daxue* and *Zhongyong* were originally written as chapters in *Liji*, and were selected for their philosophical and metaphysical import. Starting in the Yuan dynasty (CE 1313), the Four Books became the core texts of Confucian teachings for state civil examination in imperial China up to the time when the system of examination was abolished in 1905, with Zhu's commentaries considered orthodox.

Daxue consists of two basic parts: Confucius' teachings, and the commentaries by Zeng Zi, one of Confucius' students. The text provides the student a good foundation for learning. It teaches that self-cultivation is the first step in bringing the world into harmony, and describes how to cultivate one's own moral values and to exert moral influence on others. Thus, it could be said to be an exploration for the way of leadership in governing the world. It is now believed that this could be the work of Qin-Han scholars.

Zhongyong explores how one should cultivate oneself and strive to become a sage. *Dao* (the Way) figures prominently in the text and is defined in terms of *zhong* (centrality) and *he* (harmony). The notion of the triad of heaven, earth, and sage was accepted as the supreme ideal in orthodox Confucianism. In modern day language, we may consider *Zhongyong* as a human psychology text that has influenced the way the Chinese understand human nature, human aspiration, human relationships, and human learning.

Lunyu is a record of Confucius' sayings and the conversations between Confucius and his disciples. The dialogues and anecdotes could be regarded as showing Confucius at the center of relationships, and in thought and action dealing with moral and historical topics.

Mengzi consists of the recording of Meng Zi's discussions with disciples and political leaders. Meng Zi was said to have been the student of a disciple of Confucius' grandson Zisi. In this text, Meng Zi developed his teachings beyond those of Confucius, such as the original goodness of human nature, the possibility for everybody to become a sage, and the importance of humane government.

The Confucian Teachings

Song Confucian scholar Zhu Xi elevated the Four Books above the Five Classics as texts that summarized Confucian teachings. These texts, because of their complexity and because they were written in the terse and refined language of classical Chinese, have given rise to a tradition of commentaries aimed at elucidation and interpretation. In addition, the multiple meanings in the same word used to represent a construct, when applied to different contexts, often generate confusion. For example, the most important Confucian construct *ren* (translated as goodness or benevolence) might carry in different contexts the meanings of love, kindness, sympathy, warmth, tolerance, respect, caring, openness, altruism, and so on. In *Lunyu*, Confucius used some fifty applications in life situations to illustrate

the meanings of *ren* to students. Indeed, *ren* could be said to be central to Confucian teachings. We will discuss in a somewhat oversimplified way the two major themes of self-cultivation and social harmony in Confucian teachings.

Self-Cultivation

Broadly interpreted, *ren* could be said to be the quality of goodness in a person that makes the person truly human. A *junzi* is a person who practices *ren* or whose action displays *yi* (righteousness) and other virtues. Therefore, it is not surprising to find that the intrapersonal attribute of *ren* could give rise to multiple interpersonal behavioral manifestations as embodied in multiple virtues. Indeed, when Zeng Zi, a disciple of Confucius, attempted to clarify to other students what Confucius meant by the theme that ran through the teachings of Confucius, he referred to *zhong* (loyalty) and *shu* (consideration). Thus, it could be said that goodness is the one theme and that loyalty and consideration are basic manifestations of goodness.

More specifically, *zhong* (also translated as conscientiousness) could be interpreted as loyalty or being true to others as well as being true to oneself and to the true humanity in oneself. In order to be true to oneself, one has to learn to exercise self-control or self-regulation. Thus, Confucius explicitly suggested that goodness is to control oneself and subject oneself to *li* (rites). On the other hand, *shu* (also translated as altruism) could be interpreted as extending one's true self in one's behaviors towards others or to behave to others as a true human being should behave. In response to disciple Zigong's request for a saying that could always be acted upon, Confucius highlighted *shu* as to "never do to others what you would not like them to do to you."

In Confucian teachings, it seems that to be truly human is to desire spontaneously what is good, and to achieve self-cultivation requires effortful learning and education or meditation. While the path to self-cultivation is open to every individual, the process suggests a gradual and long-term development. Self-cultivation allows one to achieve enlightenment through unity with the universe, and therefore is also a process of creativity, as it is said that many great Chinese poets and artists have produced truly great art works through self-cultivation. In *Lunyu*, Confucius offered his self-cultivation as an example. The quotations are my free translation from the Chinese text.

At fifteen, I set my heart on learning.
At thirty, I established my goals in life.
At forty, I had a good understanding of people and things and was no longer perplexed.
At fifty, I accepted the givens of life, and knew what could and what could not be changed.
At sixty, I attended to truth readily and accepted them as they emerged.
At seventy, I felt free to do what I desired and was mindful not to overstep traditional rules.

Although self-cultivation could be directed intrapersonally for personal enlightenment as in the self-description of Confucius, it could also be extended to areas to allow one to become truly human at a more interpersonal or transpersonal level when the focus is on social harmony.

Social Harmony

Confucius believed that the world was controlled by an all-powerful deity, *Tian* (Heaven). It was assumed that *Tian* was aligned with moral goodness, and *tianming* (the Mandate of Heaven) was dependent on human agents to actualize. *De* is the virtue of successful rulers, without which they could not rule at all because they would not be able to maintain *tianming*. The early Zhou dynasty was the time when the ruler ruled with *de* and social harmony prevailed, in contrast to the social disharmony in the time of Confucius. To return to the social harmony of the early Zhou dynasty, Confucius was convinced that the improvement of society had to begin with the self-cultivation of the individual. Therefore, self-cultivation through learning should not only aim at achieving personal enlightenment or becoming *neisheng* (sagely within) but also should aim at contributing to society by offering meritorious services or becoming *waiwang* (kingly without).

For Confucius, the family, and relations within the family, could be regarded as a microcosm of society at large. Consequently, to achieve social harmony, relationships in society should be modeled on the ideal harmonious relationships in the family in which *xiao* (filial piety) in the parent-child relationship provided the paramount example. Within a society, there were different roles to be performed, and they were often defined in relation to other roles, giving rise to similar hierarchical relationships between ruler and minister, teacher and student, and so on. In order for the society to function harmoniously, it was vital that all members learned through self-cultivation to practice what was required of them in their various roles. Attention to rank, obligations, and ritual duties as they observed *li* would lead ultimately to the perfection of individuals and the improvement of society. The ideal social harmony or the age of great harmony (*da tong*) was described in *Liji* as a world that belonged to all people (*tianxia wei gong*). Confucius believed that *da tong* was realized at the time of Yao, Shun, and Yu. My free translation of the following quotations from the Chinese text should be illustrative (Figure 2).

When the Great Way was practiced, the world belonged to all people. The worthy and the able held government positions, and people trusted each other and lived together in harmony. Therefore, people took care of others' parents as their own parents, and others' sons as their own sons. They looked after the old. They helped the able-bodied to secure proper employment. They nurtured the young. They provided care for widows, widowers, the orphaned and the sick. Men and women worked as they took up their roles at home and outside of home. People did not allow the wasting of resources, yet they did not allocate resources only to themselves. They disliked not being able to do more for others, knowing that what they did might not benefit themselves. Therefore, there would be no plotting of wrongdoing by thieves and rebels, and people could even leave their outer gates open. This was the age of *da tong*.

Confucianism as a Conservative Force against Creativity

Confucianism was inextricably linked with the social structure and political system of imperial China. It has been used as a tool by political leaders to legitimize their rule since the Han dynasty. On this basis, modern Chinese intellectuals

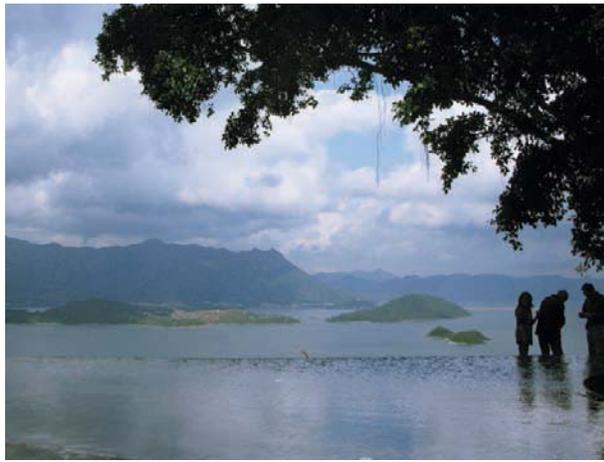

Figure 2 Heyi Pavilion, the site of Tian-ren-he-yi (One with Nature – the ultimate harmony in Confucianism) at New Asia College of the Chinese University of Hong Kong, Hong Kong.

have come to identify Confucianism with state power, with authoritarian relationships, and with rigid social hierarchies. Consequently, Confucianism is generally looked upon as a conservative force safeguarding and perpetuating the traditional order and a resistant force against China's modernization.

From *Wu Lun* to *San Gang*

A good example is provided by the legitimization of social and hierarchical relationships in society based on Meng Zi's discussion of moral and appropriate behaviors among members in society. Meng Zi referred to *wu lun* (the five relationships) as a microcosm of how individuals performed their roles in family and in society. These relationships referred to the love between father and son, the duty between ruler and subjects, the distinction between husband and wife, the precedence of the old over the young, and the faith between friends. With the exception of the relationship between friends, these relationships could be regarded as hierarchical in nature. But the hierarchy had to do with the roles and not the individuals in the relationships as they should be considered as equals in that each individual was considered to be endowed with the capacity to develop into a sage. Despite the distinctions made by Meng Zi, in later Confucian discourse starting as early as the Han dynasty, these relationships were used to legitimize a hierarchical social structure in the form of *san gang* (the three bonds) of society. The first and foremost one was the subordination of a subject or minister to the ruler, which was followed by that of a son to his father, and of a wife to her husband.

By transforming *wu lun* into *san gang*, political leaders managed to extend the boundaries of individual moral codes to social and political areas. In this way, Confucianism not only provided the state with an ideological format but also equipped the authority with the standards to judge individuals' behaviors and thoughts. Specifically, what the superiors did to the inferiors in these hierarchical relationships was interpreted as gifts (*en*) to which the inferiors should respond with gratitude (*gan'en*) and grateful behaviors (*bao'en*). Thus, *zhong* (loyalty) was the subject' grateful behaviors toward the ruler

(*bao-jun-en*); *xiao* (filial piety) was the son' grateful behaviors toward the father (*bao-qin-en*); and *jie* (faithfulness) was the wife's grateful behaviors toward the husband (*bao-fu-en*).

For many modern Chinese thinkers, especially those who came under the influence of Western education, *san gang* represented the state Confucian emphasis on the legitimized and unquestioned authority in hierarchical relationships that demanded obedience and conformity. The oppression could be regarded as discouraging individual initiatives and inhibiting creativity that involves bringing something new and useful into being.

Beyond *San Gang*: Teacher–Student Relationship

Since learning is strongly emphasized in the Confucian tradition, the hierarchical relationships in *san gang* could be readily applied to the teacher–student relationship. Thus, it is said that teachers in the Confucian tradition can be authoritarian and not allow their authority to be challenged, producing students who are docile and teachable. These teachers also tend to believe in the importance of inculcating discipline and morality in students, encouraging them to be hardworking, disciplined and respectful to teachers.

Based on these considerations, the teaching and learning of teachers and students in the so-called Confucian-heritage cultures that include China, Hong Kong, Japan, Korea, Singapore, and Taiwan has generated many research studies on Chinese learners and their academic achievement. It is said that the authoritarian nature of learning is based on a set of dogmas or assumptions regarding learning. First, education is perceived as the acquisition of correct knowledge in contrast to the conception of the discovery and generation of knowledge. Second, the written word is accepted as superior to oral discourse. This implies that a written text that is accepted as orthodox will be a text with authority that should not be challenged. Third, the teachers are regarded as the repository of knowledge to be transmitted to students. Thus, an older teacher should have a greater repository of knowledge, and should be more respected by students. However, as part of the Confucian tradition, the hierarchical teacher–student relationship might provide learning conditions that are not conducive to creativity. Indeed, the hierarchical relationship could constrain freedom of expression, self-assertion, and development of individuality in students, thus inhibiting their creativity. To counter this hierarchical and authoritarian teacher–student relationship, it is suggested that there should be a restructuring of the teacher–student relationship to one that might be considered more reciprocal and egalitarian.

Confucianism and Creative Building on the Past

Respect for Tradition

Respect for tradition is evident in Confucian teachings, which do not seem to encourage the introduction of anything new or any innovations. However, respecting tradition does not necessarily imply going against creativity. Confucius, while respecting tradition, did go against traditional or customary practices of his time in discouraging the extravagant celebration of festivities and extravagant performance of elaborated

ritual for funeral services. When his favorite student Yan Hui died, and he was in deep grief, he would not consent to an extravagant and elaborated performance of ritual in the funeral services despite the earnest requests from his students and Yan Hui's father. Thus, Confucius did not blindly insist upon returning to the ancient customs and tradition.

Although some scholars have suggested that Confucius was a creator who transformed several key traditional ideas, and the Confucian teaching of following the *Dao* could have its own sense of creativity, Confucius said the opposite. He was quoted in *Lunyu* as saying, "I transmit traditional wisdom and do not create new ideas. I believe in and admire the experiences and insights of our ancestors." However, Confucius also cautioned that to become a teacher of oneself and a teacher of others, one should always acquire and build new knowledge on the basis of what was known. In his own words in *Lunyu*, one should "review and reflect on the old in order to find out the new." Thus, Confucius seemed to imply that the study of the past was a prerequisite for the creation of new knowledge or more generally creativity.

Building on the Past

Perhaps, the conception that the new emerges from the old, or the old encompasses the new could be interpreted as the typical Chinese paradoxical thinking that denies the polarities of the old and the new. Accordingly, there should be no contradiction between respect for tradition and promotion of creativity, innovation, and invention. Indeed, in the opening paragraph of *Daxue*, the importance of learning in enabling individuals to constantly break new grounds is stressed. In a way, this learning process could be interpreted as the path of self-cultivation and the path to creativity. Again, I use my free translation from the Chinese text in the following quotations.

The way of *Daxue* is to enable the learner to recognize his inner virtues so as to bring the best out of his potentials, to inspire fellow human beings so that everyone will advance with new progress, and to facilitate this pursuit to achieve the highest level of perfection.

Zeng Zi's corresponding commentaries are also illustrative in highlighting the importance of constant self-renewal.

King Tang of Shang was said to have the following inscriptions on his bathtub to remind himself that he should "respectfully do a self-renewal once a day, do the renewal every day, and repeat renewing the renewal day after day." In addition, the Kang Pronouncement (quoting from *Shujing*) said that a good leader should encourage his people to habitually renew themselves. Further, it was said in the poem (quoting from *Shijing*) that the old state of Zhou obtained the Mandate of Heaven to rule from Shang because of its renewal.

Throughout Chinese history, there can be no doubt that art and invention have flourished even when Confucianism was dominant. There are examples of literary and artistic creativity in poetic verses of the Tang and Song dynasties, and the songs and operas of the Yuan dynasty. Gunpowder, silk weaving, paper and printing, clockwork, the waterwheel, the horizontal loom, the seismograph, and various astronomical instruments are other well-known examples of Chinese invention and innovations. While Confucianism has emphasized the call to return to the ancients, it could also be understood as a

renewing or transforming force that seeks to build on tradition and accomplishments of the past. Confucianism has demonstrated its success in assimilating or incorporating outside influences such as those from Daoism and Buddhism in the Tang, Song, and Ming dynasties, and those from systems of Western thought in the modern world. In this context, tradition is not perceived as the opposite of creativity. Rather, respect for tradition and past knowledge forms the basis for self-cultivation to achieve enlightenment, which could be the wellspring of creative work. Thus, the argument that individuals do not create and should not take credit for their creations since they only follow *Dao* or nature and discover the existing truth seems to make sense in this light.

In summary, Confucianism does not seem to have provided a well-defined perspective on creativity, nor does it seem to address explicitly any specific components of creativity, such as creative process, product, person, or press in the Western sense of the word. The question whether Confucianism could become an obstacle to creativity or could be used to promote creativity depends on how we choose to interpret Confucianism and creativity. If creativity means bringing something new into being in the Western sense, novelty is certainly not what is valued in the Confucian tradition. Indeed, in the Confucian tradition, creativity may have somewhat different meanings, and may take the form of modifications, adaptations, renovations, redirections, reconstructions, or re-interpretations, which could be perceived as the creative integration of the commitment to the past and the push for the future. These forms of transformations might serve to maintain stability and change through continuity with the past and the tradition. Thus, with this conception of creativity, Confucianism could be viewed not as an obstacle to creativity but as a potential force that has often been overlooked in efforts to promote creativity in our contemporary societies.

Glossary

Conceptual definition of creativity A product is considered creative to the extent that it is both a novel and appropriate, useful, correct, or valuable response to an open-ended task.

Construct validity The strength of the link between the term used to refer to a particular phenomenon or construct (e.g., 'creativity') and the actual features of the behavior or outcome being measured (e.g., 'degree of novelty,' 'degree of appropriateness'). Considerations of construct validity are sometimes further broken down into questions concerning both the predictive and the concurrent validity of a measure.

Convergent validity A means of establishing a test's validity by demonstrating the degree of relationship between a variety of measures of the same construct.

Ecological validity The generalizability of an experimental result to a relevant real-world population, setting, or situation.

Operational definition of creativity A product or response is considered creative to the extent that appropriate observers independently agree that it is creative. Appropriate observers are those familiar with the domain in which the product was created or the response articulated.

Reliability The reliability of a measure involves its consistency. In the case of the consensual assessment technique, reliability is measured in terms of the degree of agreement among raters as to which products are more creative, or more technically well done, or more aesthetically pleasing than others.

Validity The validity of a test or procedure refers to whether it is measuring what it is purported to measure.

Consensual Assessment is a technique used for the assessment of creativity and other aspects of products, relying on the independent subjective judgments of individuals familiar with the domain in which the products were made.

Introduction

Creativity is a concept that is difficult to define and even more difficult to measure. Since the *Encyclopedia of Creativity* was first published in 1999, the field of creativity research has seen a gradual shift away from an almost exclusive emphasis on the creative person towards a more balanced inquiry that centers both on individual difference issues and questions about the nature of creative products and the conditions that facilitate the creation of those products. But how are we to decide whether one product is more creative than another? Is it appropriate for such creativity criteria to be laid out by the researcher? Or perhaps the creators themselves should have the final say? The consensual assessment technique (CAT) for assessing creativity is based on the assumption that a panel of independent raters familiar with the product domain, persons who have not had the opportunity to confer with one another and who have not been trained by the researcher, are best able to make such judgments. Over 30 years of research have clearly established that product creativity can be reliably and validly assessed based upon on the consensus of experts. Although creativity in a product may be difficult to characterize in terms of specific features, it is something that people can recognize and agree upon when they see it.

The CAT has been successfully used in hundreds of between-subjects designs focused on the question of whether some conditions are more conducive (or detrimental) to creativity than others. The conditions to be experimentally compared can be naturally occurring (as in field studies conducted in industrial/organizational studies) or artificially created and manipulated by an experimenter in a laboratory setting. Study participants can be drawn from a single, underlying population or they might represent persons coming from different backgrounds, cultures, etc. Within-subjects designs can also incorporate the CAT to explore whether some conditions are especially conducive to or detrimental to creativity. And, again, these conditions could be naturally occurring or manipulated in the laboratory. In addition, the CAT can be used to compare product ratings made by different groups of judges. Ratings made by experts in a field can be compared to ratings made by novices. Ratings made by supervisors in the workplace or teachers in schools can be compared to ratings made by employees or students. Ratings made by children can be compared to ratings made by adults. And ratings made by judges in one culture could be compared to ratings made by judges in another culture.

The Unique Assessment Concerns of Creativity Researchers

Many empirical investigations of personality traits or cognitive styles associated with creative performance employ some form of paper-and-pencil creativity test. A variety of personality checklists, developed by Gough, Torrance, Cattell, and

others, have often been used to identify highly creative persons; however, some creativity indices have focused on behavioral factors. These behavioral assessments, such as the Torrance Test of Creative Thinking (TTCT, also known as the Minnesota Test of Creative Thinking), have typically built on Guilford's theory of divergent thinking; they elicit oral, written, and drawn (nonverbal) responses from participants.

What does it mean when someone scores high (or low) on these creativity tests? Should high scorers be considered 'creative persons'? Many creativity measures might accurately tap one or more creative abilities or predispositions, but it is most unlikely that a single test could be developed that would capture the full range of creativity components. Also troublesome is the fact that a variety of social and environmental factors have been found to influence test results. A number of studies have revealed that study participants' scores can be improved simply by telling them that creative responses will be valued. Testing environments can also influence test outcomes, and many investigations have shown variability in creativity test scores under different testing conditions and time constraints.

Even if these contextual and situational factors could be controlled for, the construct validity of many of these tests has been seriously questioned, as has the convergent validity of different test procedures considered together. This validity issue is especially problematic given the fact that many of the leading creativity tests have been validated against one another. Finally, one additional concern involves the fact that while the scoring procedures utilized in many of the creativity tests are purported to be objective, performance is often rated according to criteria based upon the test constructor's own, intuitive notion of what is creative.

Early Applications of Consensual Assessment

Mindful of these and other difficulties inherent in the creativity testing process, a number of researchers have chosen to follow a very different path. It is this group's conviction that creativity judgments can ultimately only be subjective. Rather than attempting to objectify the creativity rating process, these investigators rely on the consensual assessment of persons or products. Although, in the past, this approach was used much less frequently than creativity tests, the subjective assessment process has a long history. As early as 1870, Galton was relying on biographical dictionaries to select outstanding literary men and scientists – a technique that depended on both the subjective assessment of Galton and those who had compiled the dictionaries. Castle also used biographical dictionaries to construct an initial sample of subjects for a study of highly accomplished men and women and Cox drew her pool of geniuses for a personality study from a list of the 1000 most eminent individuals in history that had been formulated by Cattell. More recently, Simonton, in studies of sociocultural influences on creativity, developed a measure of creativity based on frequency of citation in histories, anthologies, and biographical dictionaries.

Other investigations have relied on the judgments of a select group of experts to assess the creativity of particular individuals. For example, an expert-nomination procedure

was carried out by MacKinnon and his colleagues for a series of studies in the 1960s at the Institute for Personality Assessment and Research in Berkeley, California. In order to gather their subjects, these researchers asked the dean and four colleagues at the College of Architecture at the University of California to list and rate the 40 most creative architects in the United States. Similarly, Helson and Crutchfield gathered mathematicians' nominations for the most highly creative women in their field; and Barron requested that three professors of English and one editor of a literary review suggest names of creative writers.

Shifting their focus away from the creativity of persons, some researchers have asked raters to make assessments of the creativity of particular *products*. In the majority of investigations of this type, the researcher has either presented judges with his own definition of creativity for them to apply or has trained them beforehand to agree with one another. While such methodologies may successfully avoid many of the problems inherent in paper-and-pencil creativity tests, the fact that judges have been carefully instructed in the rating process calls into question both the claim of judge-based subjectivity and the meaning of interjudge reliability. Rather than impose specific definitions of creativity or related dimensions, researchers would be better served if they allowed judges to make their own, independent product assessments. In this way, creativity assessments will more closely mirror real-world assessments.

In 1976, Getzels and Csikszentmihalyi did just this when they requested that four different groups of judges (two expert and two nonexpert) use their own individual criteria when rating subjects' drawings on originality, craftsmanship, and overall aesthetic value. Sobel and Rothenberg (1980) also utilized this subjective assessment technique when they asked their raters, two accomplished artists, to judge sketches on originality, value, and overall creative potential guided only by their own subjective definitions of these dimensions.

Investigations such as the ones described above managed to overcome much of the criticism levied against the earliest applications of consensual assessment to product creativity, yet a variety of difficulties still remained. First, many of the procedures being utilized failed to differentiate between the creativity of products and other related constructs such as technical correctness or aesthetic appeal. Further, most researchers using consensual assessment procedures did not clearly state an operational definition of creativity in their publications, even when they had trained their judges to recognize specific creativity criteria in products. Nearly all contemporary definitions of creativity are conceptual rather than operational. They were never intended to be translated into actual assessment criteria. Either investigators failed to explicitly state the definition of creativity guiding their research or they presented conceptual definitions that did not adequately reflect the rating procedures they had chosen to utilize.

Systematizing the Consensual Assessment Technique in Creativity Research

The consensual assessment of creativity was formalized and systematized by Amabile's work in the social psychology of creativity, beginning in the late 1970s. When this program of

investigation was begun over 30 years ago, existing creativity measurement tools, including available subjective assessment methodologies, could not meet the unique research requirements of investigators interested in the social psychology of creativity. The majority of available assessment techniques resembled personality or IQ tests, in that they viewed creativity as an enduring personality trait. Whether they requested that a picture be completed, unusual uses for a brick be generated, adjectives describing the self be selected, or remote associations be discovered, most paper-and-pencil measures had been specifically constructed to maximize individual differences. Even existing subjective assessment methods relied on products or entire bodies of work that depended heavily on an individual's level of expertise. Prior methods had been constructed to do exactly what social psychologists try to avoid.

Social psychologists often investigate the effect of the social environment on a person's motivation for creativity, assessing both motivation and product creativity. Effects of the social environment on product outcomes are best revealed when individual difference effects are minimized. In other words, creative performance on the task must not depend heavily on participants' specialized skills. For this reason, social psychological research requires either that the task not depend heavily on special skills, or that all study participants have roughly the same skill level. If these requirements cannot be met, then the researcher should at least assess initial skills levels so they may be controlled for in analyses.

Prior to Amabile's work, the literature had not identified a methodology that could de-emphasize individual differences between subjects. In addition, researchers had not agreed upon and consistently employed an operational definition of creativity. Amabile's first step was to adopt two complementary definitions of creativity: an underlying conceptual definition to use in building a theoretical formulation of the creative process and an operational definition to apply in empirical research.

Amabile developed the following conceptual definition of creativity: a product or idea is creative to the extent that it is a novel and appropriate response to a heuristic task. This definition is similar to a number of others that came before it. Despite the implicit emphasis on the person in creativity assessment, most explicit definitions have used the creative product as the distinguishing sign of creativity. Indeed, the criteria of product novelty and appropriateness have long been seen as the hallmarks of creativity by a number of theorists.

The CAT is grounded in the original operational definition that Amabile developed: a product or response is creative to the extent that appropriate observers agree it is creative. Appropriate observers are those familiar with the domain in which the product was created or the response articulated. Importantly, this consensual definition is based on the creative product rather than the creative process. In fact, the majority of creativity assessment techniques require that subjects produce something – a list of ideas, a series of pictures, or the like. What does set this methodology apart from the rest is that, rather than responding to a series of predetermined items or questions, subjects simply produce an actual product such as a poem, a collage, or a story.

Perhaps the most important feature of this consensual definition is its reliance on subjective criteria. In this way,

it overcomes the difficulty of attempting to specify 'ultimate' objective criteria for identifying products as creative. Indeed it may be impossible to articulate such ultimate criteria. Just as the judgment of attitude statements as more or less favorable or the identification of individuals as 'physically attractive' depends on social context, so too does the judgment of creativity. Certainly, there must be particular characteristics of attitude statements or persons or products that observers systematically look to in rating them on scales of favorability or physical attractiveness or creativity, but in the end the choice of these characteristics is a subjective one. Important writings by Gardner, Csikszentmihalyi, and others argue that creativity arises from a combination of three sources: a cultural/historical context that imposes specific symbolic rules on the creator, the creator who introduces novelty into that symbolic domain, and a field of experts who point out and validate the creative accomplishment. Thus, all judgments of creativity are necessarily relative and bounded by time and place. Creativity should not be seen as residing inside the head of the artist or scientist. Nor does it reside in a particular culture or time period or with judges representing a field of expertise within a particular era or culture. Instead, creativity must be seen as the result of a complex interaction between these three components of creator, domain, and field.

Amabile and her colleagues have attempted to capture the essential characteristics of the conceptual and operational definitions of creativity in the CAT as used in experimental studies of creativity. First, subjects are presented with tasks that leave room for considerable flexibility and novelty of response (open-ended, heuristic tasks). Second, these are tasks for which the range of appropriate responses has been clearly identified in subjects' instructions. Finally, in employing the CAT, researchers do not impose on raters their own specific views of what is creative or allow raters to influence each other; rather, raters work independently and are guided by their individual subjective conceptions about creativity.

Refining the CAT

The CAT rests on two important assumptions. First is the assumption that it is possible to obtain reliable judgments of product creativity, given an appropriate group of judges. In other words, although creativity in a product may be difficult to characterize in terms of specific features, it is something that people can recognize when they see it. Furthermore, people familiar with such products can agree with one another on this perception. A second assumption is that there are degrees of creativity such that observers can say, at an acceptable level of agreement, that some products are more or less creative than others.

Procedural Requirements

Researchers deciding to utilize the CAT should make certain that a number of requirements are met. First, the judges should all have had some experience (and roughly equivalent experience) with the domain in question. When Amabile was first developing the CAT, she and her colleagues sometimes relied

on the notion of 'expert' to describe an appropriate body of raters. Over the years, extensive work with this methodology has, however, brought about a tempering of this view. Basically, the method requires that all those rating products be familiar enough with the domain to have developed, over a period of time, some implicit criteria for creativity, technical goodness, and so on. For example, when asked to rate the creativity of paper collages, both children and adults from a variety of backgrounds have produced highly reliable assessments. When dealing with a more specialized and esoteric field, such as physics or computer programming, however, the range of 'experts' (i.e., appropriate observers) would certainly have to be considerably narrower. In either case, it is the judges' familiarity with the domain that is important, not the fact that they, themselves, may have produced work rated as highly creative.

A second requirement is that the judges must make their assessments independently. They are not trained by the experimenter to agree with one another; are given no specific criteria for judging creativity; and are not allowed to confer in their assessments.

Third, judges should be instructed to rate the products relative to one another, rather than rating them against some absolute standards they might hold for drawing, sculpture, poetry, and so on. This is important because, for most studies, the levels of creativity produced by the 'ordinary' subjects who participate will be very low in comparison with the greatest works ever produced in that domain.

Fourth, each judge should view the products in a different random order. If all judgments are made in the same order by all raters, high levels of agreement might reflect methodological artifacts.

Finally, if this technique is to be used to evaluate performance on a task to which it has not been applied in the past, judges should be asked to rate the products on other dimensions in addition to creativity. Minimally, they should make ratings of technical aspects of the work, and if appropriate, its aesthetic appeal as well. These additional assessments make it possible to examine the degree of relatedness or independence of these dimensions in subjective judgments of the products in question.

Once the judgments are obtained, ratings on each dimension should be analyzed for interjudge reliability. In addition, if several subjective dimensions of judgment have been obtained, these should be entered into a factor analysis to determine the degree of independence (discriminant validity) between creativity and the other dimensions investigated. Finally, if the products lend themselves to a straightforward identification of specific objective features, these features may be assessed and correlated with creativity judgments. Prior studies have identified some physical features of collages and some verbal features of stories that correlate with creativity judgments.

Reliability

Given the consensual definition of creativity, the most important criterion for the results of this assessment procedure is that the product ratings be reliable. In order to compute reliability, Amabile originally utilized the Spearman-Brown prediction

formula that is based on the number of judges (n) and the mean interjudge correlation (r):

$$\text{reliability} = \frac{nr}{1 + (n - 1)r}$$

This technique yields results highly similar to the Cronbach's coefficient alpha as calculated by the 'reliability analysis' procedure in the Statistical Package for the Social Sciences (SPSS). In the interest of simplicity, in recent years researchers employing the CAT have relied upon the SPSS calculation as their measure of interrater agreement. In most instances, a reliability figure of 0.70 or higher can be considered evidence of an acceptable level of agreement between judges. Once such a level is reached, it is then appropriate to compute a sum (or an average) across all ratings given each product. These sums (or averages) then constitute the unit of analysis for further computations.

By definition, interjudge reliability in this method is equivalent to construct validity: if appropriate judges independently agree that a given product is highly creative, then it can and must be accepted as such. In addition, it should be possible to separate subjective judgments of product creativity from judgments of technical goodness and aesthetic appeal. Within some domains, it may be difficult to obtain ratings of product creativity that are not highly positively correlated with judges' assessments of product technical goodness or aesthetic appeal. Yet it is essential to demonstrate that it is at least possible to separate these dimensions, otherwise the discriminant validity of the measure would be in doubt. In other words, judges might be rating a product as 'creative' merely because they like it or believe that it is technically well-done.

Supporting Data

In the program of research carried out by Amabile and her colleagues over the last 30 years, numerous studies have demonstrated that the subjective assessment technique described above does, in fact, yield reliable measurements appropriate for social psychological studies of creativity. In studies employing a paper collage task, participants are presented with a piece of cardboard, glue, and a variety of colored pieces of paper of different shapes and sizes. They are instructed to make a design that 'makes them feel silly,' and they are given approximately 15 minutes to engage in the task. In the majority of instances, professional artists and/or graduate students in the studio arts have served as the 'expert' judges. In those investigations enlisting elementary or preschool students as participants, classroom art teachers familiar with the work of children have also been recruited. For collage ratings, ten or so judges have typically been employed. Without exception, raters have yielded highly reliable assessments of collage creativity.

Equally important as interrater reliability is the requirement that judges' assessments of certain additional product dimensions do not correlate highly with their ratings of creativity. Here too the results have been very encouraging. In keeping with most theorists' conceptions of creativity, ratings of novelty and originality have typically been highly related to ratings of creativity, while ratings of various aspects of collage technical goodness have not usually been significantly correlated with creativity assessments.

In addition to the collage measure, Amabile and her colleagues have also employed a wide variety of other creativity tasks in their investigations. In an attempt to assess the impact of social constraints on verbal creativity, they have, for example, asked adults to complete five-line American haiku poems. In an effort to reduce product variability and make the judging task somewhat more manageable, study participants are typically provided with the first line of the poem they are to write. In one study, this technique was successfully adapted for use with young children. Sitting in front of a computer screen, elementary school students were prompted in a question and answer interactive format to enter one-, two-, or three-word lines. Other measures of verbal creativity that have also proven useful involve completing sentences; writing essays, descriptive paragraphs, and free-form poems; coming up with captions for cartoons; and telling a story to accompany an open-ended picture book without words. This story-telling task has been used successfully with children as young as first grade. Study participants look through the book with the experimenter and then are asked to tell a story by saying 'one thing' about each page.

Each of these verbal tasks has also yielded highly reliable creativity assessments. Whether they are poets rating haikus, elementary school teachers rating children's stories or graduate students rating cartoon captions, judges show consistently high interrater agreement.

In addition to measuring artistic and verbal performance, Amabile and colleagues have also used some creative problem-solving tasks. One assessment procedure taps spatial-mathematical creativity in children and calls for the construction of a geometric design on a computer screen. Another activity requires that young subjects fill in the outline of a geometric shape with colored pieces of felt. Problem-solving tasks involving adult subjects include the construction of computer programs, building structures from ordinary materials, generating survival ideas or ideas for high-tech products and coming up with business solutions. Although none of these techniques has been tested to the same extent as the collage-making or many of the verbal creativity tasks, it is encouraging that judges have rated products produced by children and adults with high levels of reliability.

Recent work by Hennessey and colleagues investigated whether the CAT would also produce valid and reliable creativity ratings in non-Western cultural settings. Specifically, one study recruited school teachers from the United States, Saudi Arabia, China, and South Korea to assess collages and stories created by children living in their local area. Results confirmed that across all four cultural contexts, judges' ratings of product creativity showed high levels of interjudge agreement. This suggests that the CAT is especially useful for cross-cultural investigations. Rather than impose a paper-and-pencil measure and scoring criteria originally developed for use in the West, the CAT allows for the subjective assessment of products by judges who come from the same cultural background as the study participants who produced the products.

Clearly, the CAT has wide-range application. It has been successfully employed with both child and adult subjects and allows for the assessment of creativity in a number of different domains. Over the years, subject populations have been expanded beyond the original pool of undergraduates and

elementary school children, demonstrating that the creativity of professional artists, professional art students, computer programming students, student poets, and employees of a high-tech company can also be reliably assessed. Most recently, the CAT has also been demonstrated to yield reliable assessments of product creativity across a wide range of cultural contexts. For these reasons, an ever-growing number of researchers have come to rely on this assessment technique.

Taking a Closer Look

The CAT was originally developed to yield reliable measures of the creativity of products produced in experimental studies of social-psychological influences on creativity. More recently, this methodology has also been applied to field studies in organizational settings. Whether they are asked to make a collage, tell a story, write a haiku poem, or come up with new ideas for products or solutions to problems, participants in these investigations are primarily engaged in behaviors resulting in what has been termed 'little c,' 'everyday,' creativity. The CAT has consistently been shown to yield reliable measures of product creativity in these contexts, but what is it exactly that judges are doing when they set out to make these ratings? Are they assessing only the completed product or are they also making assumptions about the process that went into producing that product? Can judges be expected to reliably assess features of the creative process? In 1994, Hennessey conducted a series of four studies with these questions in mind.

In the first of these investigations, undergraduate students rated either the creativity, technical goodness and likeableness of geometric line designs that had been created on a computer or they rated computerized replays of the procedure that went into producing each of these products. Reliability was high and raters who had been asked to make assessments of process had no more difficulty than did raters assessing finished products. A strong and positive relation was found between ratings of product creativity and ratings of the creativity of the processes that went into completing those finished products. And similar strong and positive correlations were found between ratings of the technical goodness of finished products and ratings of the technical goodness of the processes that lead to the completion of those products. In Study II, a separate group of undergraduate students made assessments of both process and finished products. Reliability was again acceptable. Judges found the rating of process no more difficult than the rating of finished products, and their ratings of process and product were positively correlated. A third study then explored whether these same results would obtain when 'real-world' drawings produced by Pablo Picasso were assessed. Undergraduates in this investigation rated videotaped segments of the processes that went into completing four Picasso drawings and stills of those drawings taken from the movie 'The Mystery of Picasso.' Importantly, these videotaped segments and stills had all been pretested on another sample of undergraduates, and not a single study participant had guessed that the drawings had been done by Picasso, or any other 'big-C' artistic master for that matter. These products were not typical of Picasso's work and were utilized simply as a matter of convenience, because a professionally-produced video of the process that

went into creating the drawings was readily available. Reliability among judges was again acceptable and correlations between ratings of process and product were of approximately the same magnitude as those obtained in the two previous investigations.

But what are judges actually doing when they make their ratings? When asked to assess product creativity, are they considering only the final product? Or do they also take into account other factors – factors such as information about the circumstances under which a product was produced or the characteristics of the creator? In investigations employing the CAT, judges are typically given very little information about the persons who have made the products they are to rate. Most often, they are instructed in the assessment process and are told simply that the materials they will be viewing were produced by university undergraduates, or preschoolers, or some other group. Implicit in this procedure is the assumption that creativity is a unitary construct independent of factors such as background or experience of the creator.

The last of Hennessey's four investigations was intended as a preliminary exploration of the impact of artist age information on judges' creativity assessments. One group of undergraduates was asked to judge collages made by children and adults after receiving accurate information about the age of the artists. A second group was asked to rate the same collages after receiving false, reversed information as to the age of the artists. Finally, a third group of undergraduates was asked to judge the collages without being given any information as to the age of the artists. Reliabilities were highly acceptable for all three of the judgment conditions, and age information was found to have a significant effect. The highest creativity ratings were given to adults' collages that had been falsely labeled as children's products. The lowest creativity ratings were given by judges who had received no age information to collages that had been produced by children. Overall, it was found that those raters receiving age information about the artists, whether accurate or reversed, gave products higher ratings of creativity than did raters for whom no age information was available. Within age information groups, no significant differences emerged between judges' creativity ratings of children's and adults' collages.

Six of the 33 judges polled reported that they had considered artists' ages when making their product assessments. Two other respondents mentioned 'fighting' against the tendency to take artist age into consideration. Contrary to expectation, it was the mere availability of age information and not the specific adult or child label that affected raters' judgments. Whether raters were given an accurate or a reversed age label, they judged children's collages to be higher in creativity than did raters given no age information. This finding suggests that creativity theorists and other researchers wishing to employ the CAT must be certain to note whether age information has been made available, either purposefully or unintentionally, to judges. Similarly, careful assessments should be conducted to determine whether raters have made any age inferences on their own.

Does knowing a subject's identity inject bias into judges' creativity ratings? This question is particularly pertinent to field studies of creativity within the realm of organizational behavior, as they frequently elicit supervisory ratings of subordinates'

creative behavior. This procedure necessitates that supervisors know the identity of the individuals who have produced the products or generated the ideas they are rating. While these studies typically control for workers' gender, age, organizational tenure, and other demographic variables that could impact creativity ratings, research has yet to determine the extent to which supervisors' attitudes, affective states or biases – such as feelings of liking and favoritism – might impact their ratings in significant ways. This issue is of particular concern because most organizational studies rely on the ratings of only a single supervisor, violating a central tenet of the CAT. However, a recent study by Baer and Oldham did find that independent ratings by two supervisors correlated highly. Of course, it is possible that both supervisors were subject to the same biasing forces. Thus, ratings of an individual's work by people who know that individual must always be regarded with caution.

Another related issue is whether individuals can make reliable ratings of the creativity of their own work. Researchers have typically found moderate correlations between creativity self-assessments and mean ratings made by others, although self-ratings often show a positivity bias. For example, in a recent study by Moneta and colleagues, workers' monthly self-assessments of their creative contributions to a project correlated moderately and significantly with independent ratings made by coworkers and supervisors. However, the mean self-ratings were higher than either the mean coworker ratings or mean supervisory ratings. Other researchers have found moderate correlations between self-ratings and peer-ratings. Indeed, a recent meta-analysis conducted by Heidemeier and Moser yielded an overall correlation of 0.22 between self and supervisory performance ratings. In sum, the literature suggests that self-ratings of creativity do relate to ratings made by external observers, but may be biased toward positivity.

A variety of papers have carefully explored these and other issues concerning the question of who should be considered an appropriate judge. In one study, parents and teachers were found to be equally accurate at recognizing the creativity of children's ideas. But other investigators found that young children's judgments about art were considerably different from those offered by older children. Runco and colleagues asked college students to each produce three three-dimensional artworks that were then rated by the subjects themselves, a group of their peers, and three professional artists. Analyses revealed that the student subjects saw significant differences in the creativity of their own three art projects. Similar differences also were reflected in the peer ratings of the artwork. The assessments made by the professional artists, however, failed to reflect significant differences in creativity between products. Thus, vast differences in level of expertise between study participants and judges may influence creativity judgments.

Dollinger and Shafran reopened the question of whether nonexpert judges might reliably rate the creativity of drawings made by a sample of nonprofessional artists. As mentioned previously, the CAT requires that researchers refrain from training judges so as not to impose their own views and risk shaping judges' ratings. However, in an interesting modification of the CAT, Dollinger and Shafran calibrated nonexpert judges' artistic creativity ratings by exposing them to 16 prototype drawings and corresponding ratings made by expert

judges in a prior experiment. Subsequent to the calibration, the mean correlation between expert and nonexpert ratings for a second set of products was 0.91.

Taken together, these results suggest that some clarification or modifications be made to the CAT specification about what qualifies as an appropriate level of judge expertise. When rating products produced by either nonprofessional or professional individuals, appropriate judges should be defined as persons whose expertise matches or exceeds the expertise of those individuals who created the products. In the case of products produced by nonprofessionals, if researchers desire nonexpert judges' ratings to correspond to ratings made by expert judges, researchers may use a calibration technique. Finally, if creativity assessment procedures require raters to have familiarity with the entire body of a given person's work – as is often the case in field research – the most appropriate judges will be those with the greatest knowledge of the subject's performance and output. Importantly, as cautioned earlier, future research should consider the extent to which knowledge about a creator's identity might bias the validity of such ratings.

Some Recent Developments

Over the years, the CAT has come to serve as an invaluable tool for a number of creativity researchers. This methodology has been extended to a variety of tasks in a variety of domains, and the diversity of subject populations and rater populations being studied is also constantly growing. Researchers have shifted from employing the CAT exclusively in tightly controlled experimental settings, to also using the CAT in quasiexperimental or field studies in which participants create products under a variety of different conditions and situations. Perhaps the most prolific expansion of the CAT in the recent decade has occurred in the organizational domain. In field studies designed to investigate the creative performance of professionals, supervisors and/or coworkers are frequently called upon to serve as raters. As noted earlier, the majority of organizational creativity studies rely on the ratings of a single supervisor per study participant. This dependence on supervisor ratings draws on a decades-long tradition in the organizational literature of using such assessments to obtain quantitative measures of an employee's performance. Although the traditional CAT involves multiple judges rating the creativity of products using a single-item scale ('creativity'), the organizational domain has adapted the CAT to involve a single supervisor who rates several subjects on a multiitem scale (e.g., 'Searches out new technologies, processes, techniques, and/or product ideas'; 'Generates creative ideas').

Investigations carried out in the organizational domain pose unique challenges that make strict adherence to the CAT protocol difficult, if not impossible. Most prominently, while it would be preferable to obtain independent creativity ratings from multiple judges, it is often difficult to find more than one person who has access to the same range of information about the work done by a given employee. Moreover, because employees often work in team contexts, the identification of a single individual's contribution to a creative product developed by a team requires knowledge about the specific set of tasks to which the individual was assigned. Due to intense

pressures in organizations, higher-level managers often do not have the time to interact with subordinates and instead rely on immediate supervisors to provide performance evaluations and feedback. Indeed, Hoegl and Gemuenden suggested that ratings made by higher-level managers reflect external market pressures more than they do the actual performance and functioning of team members. Thus, higher-level managers are seen as unsuitable judges of the creativity of most employees' work.

To circumvent these difficulties, some organizational research has employed peer ratings of creativity – requiring every member of a team to independently rate the performance of every other member. This method appears particularly promising, as it allows researchers to assess interjudge reliability. Moreover, research suggests that peer ratings are highly correlated with supervisory ratings of a target's performance, which, in turn, correlate significantly with some objective measures of creativity such as invention disclosures. The research evidence clearly suggests that it is preferable to use multiple raters (i.e., supervisors and coworkers, if available) to improve the reliability of creativity assessments in organizational studies. Nonetheless, perhaps for the sake of expediency, most organizational creativity researchers have tended to rely on ratings made by a single supervisor.

One additional arena of organizational creativity research that now frequently employs the CAT is the research on group creativity. Since the 1999 publication of this encyclopedia, the investigation of group creativity has blossomed into a distinct, multifaceted, and highly prolific field of inquiry. Early brainstorming studies in the laboratory typically employed the CAT, requiring three or more expert raters to judge the originality of each idea produced by a group. The developing body of group creativity field research – like field research on individual-level creativity – has measured creativity in a variety of ways. Some field studies have employed a single rater to assess a specific product. At other times, group creativity research has employed multiple raters assessing either a single product or the holistic creativity of a group. This CAT protocol allows for the calculation of reliability estimates, and is thus preferable to employing single judges.

Conclusions

Clearly, the CAT has been a great boon to many creativity researchers. It has broad application, is founded on a clear operational definition, and can be adapted to suit a wide variety of research situations. Moreover, with its similarity to real-world creativity judgments, the CAT enjoys a high degree of ecological validity. Despite these advantages, however, the CAT should not be considered an ultimate and universally useful means of creativity assessment. Indeed, this assessment methodology has some specific limitations. Most notably, if time concerns are paramount, this approach is decidedly impractical. Choosing an appropriate task as well as an appropriate body of judges can be extremely time-consuming, as can the assessment of products and the necessary statistical data analyses. However, a number of creativity researchers continue to believe that the benefits of the CAT outweigh its costs; and recently, Kaufman and colleagues successfully experimented

with a modified CAT technique that reduced time demands yet still yielded reliable assessments.

Perhaps the greatest strength of the CAT rests in the flexibility it affords to creativity researchers. First, the CAT can be used to obtain reliable assessments of the relative creativity (technical goodness, aesthetic appeal, etc.) of products made by a variety of individuals. Second, the CAT can be expanded to new subject populations, new performance domains, and new tasks that are quite different from those originally envisioned. In mimicking the way in which creativity is judged every day in the arts, the sciences, and the professions, the CAT helps bring creativity from the realm of the mysterious and the mystical, where it remained for centuries, into the realm of the understood and the accessible.

Glossary

Contrarianism Intentionally doing what other people are not doing. Adapted from economics, now a popular tactic for insuring originality in many other creative endeavors.

Creativity Original and useful or effective behavior, solutions, or insights. The usefulness criterion implies that contrarianism is not sufficient for creativity; contrarianism only guarantees originality.

Dark side of creativity Original and operational solutions and inventions used in immoral ways. One result of contrarianism that is not directed to creativity but is instead directed toward unconventionality.

Misplaced investments Occurs when a contrarian tactic is used, but used to the extent that the person is not investing

enough time and energy into the topic or problem itself. Time invested into being different is often time away from good focused work, and focused work is frequently necessary for creative insight.

Oppositional thinking Proclivity towards unconventional behavior. It leads persons to do what others are not, but it is often not a conscious decision and is therefore not strategic nor related to intentional creativity.

Postconventional contrarianism The recognition of rules and conventions, but making decisions for one's self. Exercising discretion before acting in a contrarian fashion. It may also be viewed as discretionary originality.

Introduction

Mickey Mouse was created by Walt Disney in the late 1920s. Mickey was a result of some collaboration; Disney worked with his brother Roy and Ub Iwerks. Disney could no longer use his 'star performer,' Oswald the Lucky Rabbit, because his old distributor held the rights. Disney needed a new star, and Mickey was conceived.

Why a mouse? As a matter of fact Walt apparently wanted a cat. He discussed this with Roy and Ub, and they decided on a mouse. That decision was implicitly contrarian. Disney and his collaborators wanted to do what no one else was doing. The character Krazy Kat was already widely known and a second feline would be unoriginal. For that reason Walt and his collaborators decided on a mouse – to be different, unique.

Interestingly, the original suggestion was to call Mickey 'Mortimer,' but Walt's wife Lily decided that Mickey was more appropriate. The discussion between Walt and Lily, summarized in *Walt Disney: An American Original*, can be described in terms of certain group dynamics and certain strategies, Walt being very contrarian, and Lily making sure that the new mouse would have a name which would sound right to the general public. 'Mickey Mouse' has a nice ring to it; and like other creative names, labels, and titles, it is fitting in some aesthetic sense. This is true of all creative insights and ideas, not just names, labels, and titles. Creative work is original, but it is more than just original. It is original and fitting.

Rationale for Contrarianism

The rationale for contrarianism is as follows: Originality is a critical aspect of creativity, and a contrarian tactic has a high probability of leading to an original idea or behavior. It is a

very practical tactic because people can think about what others are doing and then do something different and original. If you just ask them to 'be original,' they may have some difficulty. There is no criterion with which they can actually judge their originality. But if you tell them to 'do what others are not doing,' they have something concrete to think about and to use in their judgments.

It is easy to be taken in by this strategy, to be convinced of its value. There are several reasons for this.

First, as just noted, it is operational and practical. It gives individuals something they can use when judging their ideas or behavior.

Second, novel behaviors and actions are salient. For this reason the contrarian results of the tactic are easy to see. They often capture attention and are rewarding.

Third, it is an easy tactic to explain to others. Teachers, for example, can easily describe this tactic to their charges. A number of empirical projects have demonstrated how easily original thinking can be enhanced with some simple tactics.

Many biographies, autobiographies, and case studies mention contrarianism and tie it to creativity. The next section of this article reviews example cases. The pros and cons of the contrarian tactics are then explicated.

Persons Who Have Used Contrarian Strategies

Many famous creative persons have used a contrarianism tactic, in addition to Walt Disney.

Gandhi was a contrarian, especially in his methods of passive resistance. These were fitting, given his beliefs and objectives, and original. He found a way to both resist (which is in itself contrarian, at least *vis-à-vis* the British) and remain a passivist.

James Watson, who shared the Nobel Prize for his work on the structure of DNA, was contrarian in this sense. He collaborated with Francis Crick, but the competition with Linus Pauling was fierce. Sometimes competition requires contrarianism in that you do not want others to do what you are doing – or at least not until you have finished or established yourself.

In the medical research field Heimlich (who developed the Heimlich maneuver) was long known as a maverick and non-conformist. Most recently he proposed curing patients with AIDS by giving them malaria. The *Los Angeles Times* claimed that “this is not the first time the 74-year-old Heimlich’s headstrong approach to medicine has shocked, even outraged the Establishment.” Heimlich was quoted as saying, “I don’t do ordinary things. I don’t follow all the rules if there’s a better, faster way to do it” (Oct. 30, 1994: A30).

The *Los Angeles Times* also published an article, “Renegades Reinvent the Bicycle.” Apparently the mountain bike – a modification of what *Britannica* called “the most efficient means yet devised to convert human energy into propulsion” – “came out of nowhere, a product of counterculture – invented by hippies, no less, a ragtag of pot-smokers and Haight–Ashbury drifters who barely got through high school.” Note the term *counterculture* – a group of contrarians.

A final example from the *Los Angeles Times* can be given. I am referring to Rock ‘n’ Roll. In a 1998 Times book review rock is called “a disagreement with established power – a refutation of authority’s influence” (4/15/98, p. E6).

Nor is rock ‘n’ roll the only rebellious kind of music. Duke Ellington was, for instance, quite the contrarian. Arnold Ludwig, MD, author of *The Price of Greatness*, explained how this response style can play an important role in creativity . . . illustrated, for example, in the compositions of Duke Ellington. Knowingly or not, Ellington exploited traditional musical rules as inspiration for his jazz. If he learned that he was not supposed to use parallel fifths, he immediately would find a way to do so; if told that major sevenths must always rise, he would write a tune in which the line descended from the major seventh; and if the tritone was forbidden, he would find the earliest opportunity to use it and, to emphasize the point, would let it stand alone and exposed (pp. 7–8).

The comment, “knowingly or not” is critical because by definition tactics and strategies are intentional. Unintentional contrarianism may best be viewed as *oppositional thinking*, which Ludwig defined as “the almost automatic tendency to adopt a contrary or opposite response” (pp. 7–8).

Ludwig gave Freud as a second example. Certainly Freud’s work was original, and yet it fit with his observations and with certain lines of medical theory. Freud was oppositional, and perhaps contrarian, in his efforts to do original work and in his nonconformity.

In the arts, Picasso described cubism as follows: “We were trying to move in a direction opposite to Impressionism.” This is pure contrarianism, especially in the direction – namely, opposite to Impressionism. It is not just a reaction to others, and not just different, but *opposite*.

Stephanie Dudek argued that the Dadaists and Surrealists were “particularly determined to burn all bridges behind them.” In this light, contrarianism breaks with traditions. That implies that *avant-garde* is inherently contrarian. As Dudek put it, *avant-garde* is “by definition art that is ahead of its time,

that is shocking, disturbing, and therefore viewed as socially objectionable. Its specific aim is to undermine the existing order and to replace it by another. It attempts to do this by contradiction, challenge, confrontation, and self-assertion.”

Turning from the visual arts, consider Bruce Lee. He developed an original system of martial arts – Jeet Kune Do – but had to fight the establish schools because they did not want to teach any such techniques outside of Asia.

Howard Gruber described how the famed developmental psychologist Jean Piaget used several specific strategies used in his work.

First, he suggested that he always thought with a pencil in his hand. This is a simple but useful tactic, given how fleeting creative insights can be. Second, Piaget read outside his own field. Third, he did not read inside his own field. And last, he always had target or “whipping boy.”

B. F. Skinner also suggested that scientists read outside their own field. This is a kind of contrarianism. Focusing on what goes on outside one’s own field, and thus avoiding one’s own field, is even more contrarian.

Dr. Seuss, prolific author of children’s literature, broke rules on every page of every book. He made up his own words, used many an ungrammatical sentence, and defied the laws of physics in the actions of his characters. Gertrude Stein and E. E. Cummings also come to mind; they too broke certain literary traditions.

Although instructive, these cases – Disney, Gandhi, Heimlich, Ellington, Freud, Picasso, Piaget, Skinner – are famous creators. Generalizations from them are therefore questionable.

Contrarianism in the Service of Creativity

Two distinctions will help to insure that contrarianism is in fact associated with creativity. First is the distinction between contrarianism and oppositional thinking. The former is intentional and the latter an unintentional tendency toward nonconformity and unconventionality. Similarly critical is the distinction between contrarianism that is intentionally used for the sake of creativity, and that which is used merely to insure originality and salience.

Contrarianism does not guarantee creativity; it can have other results or be directed to other objectives, including originality. But originality does not insure creativity; it is necessary but not sufficient. It follows that contrarianism for the sake of originality may lead only to deviance and not to creativity.

Salience is a possibility because contrarianism does lead to originality – the contrarian is different and unique – but this can just attract attention. Original behaviors and actions are salient. They grab our attention. Creativity, on the other hand, probably is much more likely when the intention is creativity. This is *contrarianism in the service of creativity*. When that is the case, there will be some fit, some appropriateness, as well as originality. Recall here that creativity requires both originality and appropriateness. Contrarianism only contributes to the former and can inhibit the latter.

Even contrarianism in the service of creativity, there are potential problems. First is what has been called *misplaced investments*. This occurs when the creator uses a contrarian

tactic, but does so to the extent that he or she is not investing enough time and energy into the topic or problem itself. Time invested into being different is often time away from good focused work.

A second potential problem is that contrarianism can lead the individual to break rules that should not be broken. It may be that the creator is reinforced for contrarianism because it leads to creative insights, but then fails to exercise discretion and applies the same tactic in areas where some conventionality should be respected. In fact, Feldman, Gardner, and Csikszentmihalyi in 1999 and Gruber in 1993 proposed that moral and humanitarian values in work and creative efforts should be clearly encouraged. If contrarianism leads the individual to break the important rules that keep society running smoothly, we have yet another example of what Robert McLaren called *the Dark Side of Creativity*. Examples of this were given by Russell Eisenman and Richard Brower in the Special Issue of the *Creativity Research Journal* which was devoted to Creativity and Deviance. Brower provides long lists of eminent creators who have spent time in jail.

Creativity as Postconventional Contrarianism

One useful way to think of contrarianism is as postconventional creativity. This term is used in developmental theories. It is a third stage and follows the preconventional and conventional stages. A child in the first of these stages is unaware of rules, norms, and conventions, and in fact does not recognize the value of rules. His or her games are ever-changing; there are no stable rules to keep them moving toward an objective. Moral judgments at this age are based on rewards and punishers rather than a sense of right and wrong. The child is, however, often quite creative in art and expression. Ask a group of preschoolers to draw pretty trees and you will get mostly trees without green leaves. They pick their colors based on preference rather than convention.

Not so individuals in the conventional stage. They are well aware of rules – and in fact hold to very literal interpretations of them. They see the value of conventions for fitting it, but

sometimes put a bit too much effort into doing just that. The result is a tendency away from anything unconventional and original. Conventional individuals respond to peer pressure and hate bending rules. This explains the fourth-grade slump, when many children become noticeably less original in their ideation. Conventionality also leads them to a literal use of language, and it certainly is apparent in their playing games (by the rules) and their art. Children in this stage are likely to draw trees that will very likely have green leaves.

The third stage is postconventional. Here the individual is aware of rules, norms, and conventions, and typically abides by all. He or she does, however, make decisions for him- or herself. Conventions are taken into account, but so is the immediate context. If asked to draw “what trees look like,” leaves may very well be green, but if asked to draw what trees should or could look like, the leaves may be rainbow colors or whatever color is the individual’s favorite.

This same capacity to recognize conventions but think for one’s self is exactly what was meant earlier by exercising discretion. With that kind of discretion, contrarianism will be used appropriately, for creativity.

Creative Environments, Conditions, and Settings

D M Harrington, University of California, Santa Cruz, CA, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Audience Any person(s) other than the original creator(s) who come(s) in contact with a novel act or product in any field. Not restricted to viewers of performances.

Autonomously creative people People such as artists, designers, garage inventors, writers, and some academics who carry out much of their relatively solitary and unsupervised creative activity outside of organizations. As made clear in this article, however, such people are by no means entirely autonomous in their creative work.

Coworking spaces Settings which offer a combination of individual and communal work spaces to autonomously creative people who would otherwise probably work by themselves and often at home. The settings are designed to facilitate socializing, potentially synergistic exchanges of information, and opportunities for possible collaborations among people working in different domains. Contemporary amenities such as coffee and internet access are typically provided to create a modern cafe-like environment.

Creative cities Cities such as Paris, Vienna, and New York City which have been the site of historically noteworthy creative efflorescences in particular creative fields during certain periods of time.

Creative environment The physical, social, and cultural environment in which creative activity occurs. Creative environments may involve nested environments,

for example, an office space nested within a home, nested within a neighborhood, nested within a city, nested within a particular time in history.

Creative seeds The initial 'seeds' around which creative interests and activities first develop. Seeds may consist of problems or projects presented or discovered. Seeds may also consist of new ideas, perspectives, images, sounds, objects, materials, processes, or tools which elicit the curiosity and attention of creatively inclined people and which eventually evoke creative activity. Seeds are sometimes experienced as emerging from the self in the form of powerful images, mysterious phrases, haunting feelings, or dream fragments from which creative activity evolves.

Creatively active person A person who is currently engaged in a creative activity.

Creatively inclined person A person who tends to enjoy certain types of creative activity and who has a history of voluntarily, and often enthusiastically, undertaking those activities.

Designated and protected workspace A special type of workspace that is 'designated' in the sense that it is intended to be used primarily or exclusively as the person's central place of creative work and is 'protected' in the sense that it is not to be intruded upon, re-arranged, or 'cleaned up' without permission. These spaces may take many forms, including that of offices, studios, garages, basements, or even old barns.

Introduction

Creative environments help people function more creatively than they would in less creative environments. In view of the fact that other articles in this encyclopedia describe environmental factors which influence the creative functioning of people working within organizations, the present article will focus on environmental factors which tend to facilitate the efforts of autonomously creative people such as writers, artists, designers, garage inventors, and some academics, who carry out much of their creative work without the support, supervision, or resources which organizations typically provide.

This article will focus on five aspects of the creative working environments which such people often seek out or construct for themselves: (1) the physical spaces in which they often do much of their work (e.g., studios, offices, garages, workshops, and libraries); (2) creatively supportive spouses, partners, and friends; (3) informal settings such as cafes, bars, and creatively-active neighborhoods which facilitate interactions with other people involved in similar creative activities; (4) settings that have been designed specifically to foster creative work such as

artists' collectives and colonies, writers' retreats, and centers for advanced studies.

Need for a Conceptual Framework

The systematic study of environments which help support the work of autonomously creative people is much less developed than the study of environments which support the creative activities of people working within an organization. For example, whereas conceptual frameworks and related questionnaires have been developed and used to study work-settings and climates associated with creative performance within organizations, no such frameworks and almost no psychometric instruments exist for studying the multi-layered environments within which autonomously creative people function. In preparing to write this article, therefore, it was necessary to construct a conceptual framework that might be useful in organizing and making sense of what might be known about the kinds of environments that autonomously creative people tend to construct or seek out for themselves and about the actions they take in doing so. Once constructed, this framework was then used to help interpret descriptions of

those environments and of the actions taken to construct or seek them out.

A Conceptual Framework

The conceptual framework developed here rests on two working assumptions: (1) creative activities and projects present a variety of challenges to people who are attempting to initiate and carry them out; and (2) many of the qualities which tend to distinguish creative from less creative environments involve functional features of environments which help creatively-active people meet those challenges. For example, because many creative activities involve phases during which multiple strands of thought are being dealt with more or less simultaneously, those activities present creative people with the challenge of simultaneously handling several strands of thought. As a consequence, environments which make it easier for creatively active people to handle multiple strands of thought when the need arises, should be expected to support, on average, somewhat higher levels of creativity than environments which serve this function less effectively.

The specific framework described below and used throughout this chapter was developed by: (1) compiling a list of widely cited and presumably relatively common features of creative activities and episodes; (2) drawing inferences about the challenges those features would tend to present to people engaged in creative activities; and (3) drawing predictive inferences about the functional characteristics of environments that would tend to help people meet those challenges.

It is important to understand at the outset that the ways in which these challenges affect creative people and the creative working environments they construct in efforts to deal with those challenges almost certainly reflect the personality and cognitive characteristics, working styles, and personal preferences of the individuals involved as well as the nature of their typical creative activities and projects. Therefore, though it may be possible to sketch the general contours of 'typical' creative environments, the most creative environment for any particular person at any particular time is very probably a matter of person-project-environment fit.

Predicting the Functional Characteristics of Creative Environments from an Understanding of Creative Processes and Episodes

Creative Episodes: Common Elements, Features, and Associated Challenges

Creative episodes of the type being discussed here typically begin when creatively inclined people, (i.e., people who generally enjoy engaging in certain types of creative activities and who have a history of doing so) come in contact with pre-defined projects or, more commonly, when they encounter or generate creative seeds from which they construct motivationally appealing projects.

Creatively inclined people

Because creativity requires the presence and actions of a creatively inclined person, a creative environment must

contain at least one such person. Furthermore, because creatively active people often stimulate and amplify one another's creativity in ways that will be described below, adding creatively inclined people to an environment will tend to increase the level of creative activity within it. The challenge for potentially creative environments, therefore, is to attract and retain creatively inclined people.

Creative seeds and projects

Autonomously creative people are sometimes presented with more or less clearly defined projects in the form of invitations, competitions, or commissions which they are free to accept or ignore. In other cases, autonomously creative people decide to undertake more or less clearly defined projects which are available in the social or artistic-intellectual milieu as tasks which they are free to engage or ignore. Writing the Great American Novel, writing an essay explaining in convincing detail how consciousness arises from activities of the brain, or constructing an engine that will propel an automobile for 100 miles on a gallon of gas, are examples of projects that reside in the culture, and can be undertaken by anyone.

More commonly, however, creatively autonomous people construct their own projects from what may be thought of as creative 'seeds.' Seeds may come in the form of new ideas, images, sounds, objects, materials, processes, tools, and ways of thinking which are encountered in the outside world, which catch the attention of creatively inclined people and from which they construct new projects relevant to their long-standing creative interests. For example, a snippet of conversation overheard on a busy sidewalk might become the seed for a new song, a detective novel, or nothing at all, depending upon whether it was overheard by a singer-songwriter, a writer of detective novels, or by someone who is not creatively inclined. Creative people also sometimes experience seeds as emerging from within themselves in the form of dream fragments, powerful feelings, visual images, or ideas for possible projects that pop unexpectedly into consciousness. In other instances, creative seeds emerge from creative people's explorations and playful manipulations of the materials with which they typically work.

The challenge for creatively inclined people, therefore, is to place themselves in situations where they are apt to encounter potential projects or seeds, or in which 'internal' seeds are apt to arise, or in which they are apt to engage periodically in goal-free explorations and playful manipulations of the materials in which they work.

The corresponding challenge for environments is to provide such seeds and projects and to provide conditions conducive to their generation. Environments which serve these functions well should be expected to support, on average, higher levels of creativity than environments which serve these functions less effectively.

Motivation

People are motivated to initiate and carry out creative activities by a wide range of anticipated and experienced pleasures and satisfactions, some of which flow directly from the activities themselves, and others of which are contingent upon actual or anticipated reactions from the outside world. The first category would include, for example, the pleasures people often derive

from using their own imaginations, from manipulating their projects' physical materials, or from creating or discovering new things.

Though sometimes de-emphasized by scholars more focused on the first category of pleasures and satisfactions, many of the satisfactions, pleasures, and rewards which are contingent upon reactions from the outside world play very important motivational roles in the working lives of creative adults. Many professionally creative people, for example, are substantially motivated by the hope that their work will be recognized and valued by their professional peers. Some are strongly motivated by desires to produce work that informs, gives pleasure to, enriches, or in some way benefits other people. Most professionally creative adults who are financially responsible for themselves and perhaps others are also motivated by the hope that their creative work will contribute to their financial well-being.

There are several challenges to creatively inclined people related to this issue. It is important that they undertake creative activities from which they are apt to derive process-based pleasures and satisfactions. It is also usually important that they undertake projects which have reasonably good chances of evoking the kind of socially contingent recognitions, rewards, and responses they desire.

The corresponding challenges to creative environments are to (1) give people the freedom to choose activities from which they are apt to derive process-related as well as socially-contingent pleasures and satisfactions, (2) contain a wide range of 'audiences' that value a variety of creative products and are capable of and inclined to appropriately reward those who produce them. Environments which serve these functions well would be expected to support higher levels of creative activity than environments that do not.

Information

Psychologists generally believe that creativity almost always involves combining, building upon, and transforming pieces of information, constellations of knowledge, ideas, images, sounds, theories, perspectives, and ways of thinking that are encountered in the external world prior to or during any particular creative episode or which are generated in the course of the episode.

The challenge to creative people is to possess such information at the outset or know how to acquire it quickly during the episode. The corresponding challenge for creative environments is to contain such information and make it easily available to creative people or to facilitate the acquisition of such information from other environments.

Time

Creative people generally want to spend as much time as necessary on their projects. Creative people also often wish to exercise considerable control over how the total time available to them is configured. For example, some creative people can work effectively in many short blocks of time whereas others need long periods of time. Some autonomously creative people have very strong preferences regarding the time of day and, in some cases, even regarding the time of the week or year in which to work. In addition, people often want to be able to plunge quickly into their creative work in response to suddenly emerging ideas or to a strong sense that conditions are 'right.'

They also frequently wish to keep working for as long as the process is going well.

The challenge to creative people is to find or 'make' as much time as possible for their creative work and to find ways to control the configurations and availability of their work time as fully as possible.

The corresponding challenge to creative environments is to help people find or make sufficient work time and to make it possible for them to configure and access that time as needed.

Space

Most creative activities require space. In some cases this may involve little more than a place to sit, though in other cases it may involve larger and more complex spaces in which to store and use materials and equipment. Furthermore, as noted below, the spaces also may need to satisfy other special requirements.

The challenge to creative people is to locate or create such space. The corresponding challenge to creative environments is to provide such space or make it possible for people to construct or locate space that meets their needs.

Reliance upon easily disrupted concentration

I find it is very important to work intensively for long hours when I am beginning to see solutions to a problem. At such times atavistic competencies seem to come welling up. You are handling so many variables at a barely conscious level that you can't afford to be interrupted. If you are, it may take a year to cover the same ground you could cover otherwise in sixty hours.

Edwin Land, inventor of the Polaroid camera,
quoted in Bello, 1959, p. 158

As illustrated by Edwin Land's comment above, and as echoed by countless others, creative people often need protracted and uninterrupted periods of time during which they can become totally absorbed in their work and be able to handle the multiple elements and strands of thought frequently involved in creative thinking.

The challenge to creative people is to create or locate time and space in which such uninterrupted absorption in their work is possible. The corresponding challenge to creative environments is to provide the space and time necessary for such periods of uninterrupted concentration.

Reliance upon experimentation, exploration, and partially guided trial and error

... but sometimes the poem had to be taken in hand and completed by the brain, which was apt to be a matter of trouble and anxiety, involving trial and disappointment, and sometimes ending in failure.

A. E. Housman, in Ghiselin, 1985, p. 91

A. E. Housman's observation regarding his own writing process is typical of those made by creative people in almost all fields who frequently find themselves relying upon experimentation and partially guided trial-and-error in the course of their creative activities. In remarking upon the fact that such efforts often elicit anxiety and a sense of trouble and possible disappointment, Housman also describes feelings that are widely experienced and frequently expressed by creatively active people who realize, correctly, that resorting to trial and

error may mean that they are facing problems in their work which may require unpredictably long periods of time to solve or which they may not be able to solve at all. The challenge to creative people is to avoid, minimize, or manage such feelings and fears sufficiently that they do not disrupt or halt their creative work. The corresponding challenge for creative environments is to help people avoid, minimize, or cope with such feelings of anxiety and distress.

Reliance upon nonconscious cognitive processes

Creative people sometimes experience their work as being dependent upon the functioning of cognitive processes which are largely beyond their conscious awareness or control and which may or may not produce useful ideas. In some instances the products of these seemingly nonconscious processes pop up quite unexpectedly while people are engaged in relatively mindless everyday actions such as walking or taking showers, especially after having recently engaged in fairly intense periods of work on the project. In other cases, however, people attempt to engage these rather elusive processes by intentionally establishing what they consider to be particularly helpful internal and external conditions. Though such conditions sometimes include idiosyncratic sensory cues, they are often characterized by lack of distractions, a sense of peace and quiet, and sometimes the presence of an aesthetically pleasing visual scene. Such times and spaces, it should be noted, may be similar in some important respects to those needed for periods of creative absorption and concentration.

Reliance upon these marginally controllable and unpredictably helpful processes can also stir feelings of anxiety and doubt similar to those elicited by reliance upon experimentation and guided trial and error.

The challenges to creative people include making or gaining access to times and spaces which seem to facilitate conscious contact with the products of these processes, arranging propitious external and internal conditions, and avoiding or managing the anxieties sometimes associated with reliance upon these processes. The corresponding challenges to creative environments are to help make such times and places available and to help people avoid or manage the feelings of anxiety and self-doubt sometimes associated with dependence upon these processes.

Physical materials and tools

Most forms of creative activity require the use of certain physical materials, tools, and instruments. The challenge to creative people is to gain access to such materials and tools. The corresponding challenge to creative environments is to provide access to such materials and tools.

Assistants

Creative activities initially undertaken as one-person projects sometimes require more knowledge, skills, energy, and time than one person can provide. The resulting challenge to people centrally involved in such projects is to identify their need for assistants and to locate and recruit them. The corresponding challenge to creative environments is to help people identify their need for assistance, to contain and provide easy access to potential assistants, and to facilitate their identification and recruitment.

Tentative completion

Creative projects must eventually be brought to at least tentative completions despite their imperfections and undeveloped possibilities. The challenge to creative people is to at least tentatively complete their projects despite unavoidable uncertainties as to whether these imperfect products are good enough. The corresponding challenge to creative environments is to help people make good decisions about when to consider a project 'finished.'

Projection into and reception by the outside world

If creative products are to provide those who create them with the socially contingent benefits they need and desire and if the products also are to benefit people for whom they were created, they must be projected into the outside world and made visible to audiences (broadly construed) that are capable of recognizing, rewarding, and responding to them in motivationally satisfying ways. The challenge to creative people is to help project their finished products into the outside world where relevant audiences will become aware of them. The challenges to creative environments are to contain a wide range of audiences which are interested in a variety of creative products and which are also capable of rewarding those who created them, and to help creative people project their work to relevant audiences.

Pervasive uncertainties

Creative projects of the sort discussed here are fraught with uncertainties from start to finish that can threaten their successful completion. Because creativity, by definition, involves doing something that has never been done before, creative projects often lie somewhat beyond people's initial zones of competence. Successful completion of such projects therefore often depends upon whether, while engaged in the activity itself, people are or are not able to strengthen their initial skills and are able to acquire new skills, strategies, and information needed to complete their projects. As noted above, frequent reliance upon unpredictably successful periods of exploration, experimentation, and guided trial and error and upon marginally-controllable and unpredictably effective nonconscious processes are additional sources of uncertainty. Further layers of uncertainty are added by the fact that it is often very difficult to know whether a tentatively completed product is ready to be projected into the world, whether it will be possible to project a finished product into the world and whether, once there, it will be noticed by audiences who will provide the desired responses. Unless avoided or managed effectively, the anxieties, misgivings, and self-doubts produced by these uncertainties can prevent people from even initiating projects which they fear will include excessive levels of uncertainty. Unless avoided or managed, these feelings can also lead to disrupted and constricted thinking during the creative activities themselves, to the premature completion of projects, to endless perseverance, or to the total abandonment of projects which might have been completed successfully had such reactions been avoided or managed.

The challenge to creative people, therefore, is to avoid, subdue, or somehow manage all of these potential anxieties, misgivings, and self-doubts. The corresponding challenge to creative environments is to help people avoid or manage these process-threatening thoughts and feelings which are grounded in the unavoidable uncertainties associated with creative activity.

Constructed and Sought-Out Environments

This stage of the analysis involved three steps: (1) identifying recurring patterns in the actions which autonomously creative people have taken to construct or seek out environments to support their work; (2) identifying salient characteristics of those environments; and (3) pointing out possible connections between those characteristics and the challenges which creative activities often present. Creatively active people and potentially supportive environments which were predicted in the section, 'a conceptual framework.'

The first two steps relied most heavily upon qualitative descriptions written by autonomously creative people of the environments they have constructed or sought out for themselves and of particularly creative environments in which they have found themselves fortuitously situated. Descriptions of such actions and environments which have been produced by journalists, biographers, sociologists, and historians were also examined. These two steps were also informed by historiometric studies which have examined macro-level factors which appear to have influenced levels of historically noteworthy creativity and by a few studies in which creative people have been asked to identify environmental factors which they believe influence their creativity.

Actions Taken by Autonomously Creative People to Construct or Seek Out Supportive Environments

The following five broad themes recurred with notable frequency in the descriptions of actions taken by autonomously creative people to construct or seek out creatively supportive environments for their work:

1. A tendency to construct or seek access to designated and protected work spaces.
2. A tendency to establish relationships with spouses, partners, and friends who support their work.
3. A tendency to establish supportive connections with other people engaged in creative activities similar to their own.
4. A desire to work in settings such as artists' colonies, writers' retreats, and centers for advanced studies.
5. A tendency to be drawn toward cities or regions in which unusually high levels of creativity are occurring.

Though it is currently impossible to estimate accurately the frequency with which these tendencies are exhibited, it is probably safe to say that almost all autonomously creative people exhibit at least one and probably two or more of these behaviors and aspirations.

Designated, protected, and easily accessed work spaces

People certainly do some of their important creative thinking and work beyond the confines of their standard work settings. Good ideas, for example, are frequently reported to appear while walking, taking showers, or immediately upon waking from sleep. However, people do much or most of their creative work in settings which they consider to be their primary places of work. It appears that a large percentage of people involved in relatively solitary and autonomous creative work construct or seek out primary places of work for themselves which may accurately be described as 'designated and protected' work spaces. These spaces

take many forms, including that of offices, studios, garages, basements, or even old barns. These spaces are 'designated' in the sense that they are intended to be used primarily or exclusively as the person's central place of creative work. They are 'protected' in the sense that those who use them often make clear to other people that the spaces are not to be intruded upon, re-arranged, or 'cleaned up' without permission. The 'protected' quality of these spaces certainly calls to mind Virginia Woolf's famous suggestion to aspiring young women writers that they manage to obtain rooms of their own 'with a lock on the door.' Many people also try to make these workspaces quickly accessible by establishing them within or very near the structures in which they live, though others find it easier to maintain the designated and protected quality of these spaces if they are clearly separated from where they live. Ideally these spaces also can be equipped and arranged to suit the user's particular needs and work style. Such work spaces serve many functions in the process of supporting their users' creative activities.

Help sustain concentrated and meditative thought

For many people, the most valuable aspect of such spaces is the fact that they provide the physical and psychological space needed to engage in the uninterrupted and undistracted periods of absorbed, concentrated, and sometimes meditative thought which are so often crucial to their creative work. The fact that such spaces give people opportunities to become totally immersed in their own creative work and in their own created worlds is noted repeatedly and emphatically by people who work in such spaces.

By permitting people to leave work-in-progress (e.g., unfinished canvases, pages ending in mid-sentence, partially completed gadgets, etc.) safely undisturbed between periods of work, these workspaces expand actual work time somewhat by reducing set-up time. This feature also helps people quickly re-enter their previous frames of mind and easily pick up threads of thought which were laid to rest at the end of the last period of work.

For reasons of necessity and preference, some workspaces are less than fully designated or fully protected. For example, people who enjoy occasional interruptions and perhaps find them beneficial tend to construct somewhat more permeable spaces. Those who must remain within sight or sound of other people for whom they are caring either tend to construct much more permeable workspaces or, more often than not it would seem, defer their creative work to times when they are relieved of those responsibilities and can enter more protected workplaces. More generally, those constrained by practical impediments, often find ingenious ways to construct or seek workplaces that serve some of the functions of designated and protected workplaces.

Safe space for small 'failures'

Such settings also function as psychologically 'safe' spaces in which it is possible to engage in the frequently unsuccessful experiments, explorations, and partially guided trials-and-errors so often characteristic of creative work without fear of having others witness these many small 'failures.'

Motivational support and encouragement

Such work spaces can provide modest motivational support and encouragement in at least three ways. Because they can be

arranged to meet the creative worker's individual tastes, they presumably slightly enhance the pleasure experienced while working within them. In addition, if such spaces are used almost exclusively for creative work, the simple process of entering them will tend to trigger and encourage, by means of automatic and largely unconscious processes, the kind of focused creative work behavior that has come to be associated with that space. Furthermore, if these spaces have been the site of previously successful work, they may somewhat enhance motivation by eliciting memories of those successes.

Freedom

The private and unsupervised nature of these spaces also gives those who work within them considerable freedom to work on their projects in whatever ways they choose. The exercise of such freedom tends to increase the probability of creative success in two ways: by maximizing person-project and person-method 'fit' and, according to self-determination theory, enhancing the motivation to engage in the chosen activity.

Accessible materials and tools

Such workspaces facilitate creative work by making the necessary materials and tools easily accessible. The challenges associated with obtaining such materials and tools in the first place, however, must be met through interactions with the outside world.

Information

Such workspaces can also help satisfy some of the information-related needs of creative projects by containing resources such as personal reference libraries and collections of art books and musical recordings. Though workplace connections to the internet provide access to vast bodies of easily accessed information, not all of the information people need in the midst of their creative activities exists in digitally accessible form. As noted below, therefore, autonomously creative people must often turn to the world beyond their immediate workspaces to gather information they need.

Exceptions: People who dislike working in social isolation or are unable to do so

Designated and protected work settings obviously do not meet the needs of people whose circumstances prevent their constructing or locating such environments. Nor do such workplaces meet the needs of people who find it psychologically uncomfortable to work in such socially isolated settings and who therefore move their work to settings where they will, at the very least, be within sound and sight of other people. Writers, for example, have often used cafes or restaurants as places to work near other people and within reach of desired beverages which may or may not enhance the creative workings of their brains. In the 1990s, for instance, J. K. Rowling wrote parts of her first Harry Potter novels in a neighborhood cafe with her infant daughter in a nearby stroller and an espresso close at hand. Over the years writers who have found rooms of their own nonexistent or too isolating have sometimes turned to great public writing rooms such as the British Library's Reading Room to do their work. There, for example, Charles Darwin and Karl Marx thought and wrote in a setting supportive of concentrated thinking yet in the

presence of other people and in close proximity to vast resources of information.

Supportive spouses, partners, and friends

Supportive spouses, partners, and friends are frequently very important elements in a creatively active person's environment. For example, autonomously creative people often acknowledge the important role played by people with whom they live in helping establish and protect their work place. Spouses and partners are also often thanked for tolerating work patterns that sometimes deviate substantially from the social norm, by occasionally freeing up work time by relieving the creatively active person of some household obligations, and by tolerating problematic behaviors and mental states sometimes associated with intense involvement in creative activity. Spouses, partners and friends are also frequently identified as influential sources of personal encouragement and as people who affirm the fundamental value and importance of the kind of creative work being done. In some cases spouses and partners also serve as sounding-boards, first audiences, helpful critics, and friendly editors. It is presumably not by chance that creative people often establish and maintain relationships with people who support their work in these ways.

Settings for informal contact with peers engaged in similar creative activities

Cafes and bars

Autonomously creative people in Europe and the United States have often used cafes, bars, and restaurants as places to meet and mingle with one another during or at the end of their workdays. The cafe life of Vienna and Paris, for example, has often been cited as an important factor in sustaining the creative ferment of these two cities during certain periods in their history. Historians and sociologists of art and literature have also cited the roles played by particular bars in the emergence and development of bebop jazz in Harlem in the 1940s, the New York School of artists and poets in the 1940s and 1950s, and the development of the beat poets in San Francisco's North Beach in the 1950s. (Interestingly, certain restaurants have also been cited as playing important roles in the productive back-channel exchange of information that helped fuel Silicon Valley's creativity.) In such settings creative people are able to satisfy some of their needs for social contact that may have been unmet during hours of relatively solitary work. Here, too, they are able to participate in conversations and creative interactions with other creatively active and intellectually lively people who expose them to new and, perhaps, the very newest, ideas, perspectives, and methods in their field of work. Valuable information about possible venues and outlets for their work and about intermediaries who might help project their work in the larger world is also sometimes shared and gathered in these conversations. Within such gathering places, autonomously creative people often experience strong general affirmations regarding the importance and ultimate value of the kind of work in which they are engaged, as well as more personally directed expressions of encouragement, find extremely important encouragement and motivation implicitly and explicitly provided by other creatively active and therefore highly credible people.

Informal associations

Creatively autonomous people also sometimes seek creative support and stimulation by establishing friendships with other creatively active people or by joining informal groups to share ideas, work and constructive critiques in supportive environments. The Noble laureate, Toni Morrison, for example, reportedly received crucially important support at the outset of her writing career from a small group of writers who gathered monthly to share and discuss one another's most recent work.

Writers' rooms and coworking spaces

Recent years have seen the emergence of writers' rooms which provide private (semi-protected) writing spaces for concentrated work as well as modern amenities such as coffee and internet access. These writers' rooms often include communal spaces which can be used to socialize and, if desired, exchange ideas about work in progress. Along very similar lines, 'coworking spaces' have been established to serve the needs of people involved in a variety of autonomous creative activities and who would otherwise work at home. These coworking spaces typically offer private and semi-protected work spaces, the usual amenities, and communal spaces very specifically designed to facilitate socializing, potentially synergistic exchanges of information, and possible collaborations between creatively-active people working in different domains.

Creatively active neighborhoods and enclaves

For centuries, and continuing to this day, artists of various sorts have migrated to neighborhoods and enclaves which have become heavily populated by other artists and creatively active people. In so doing they place themselves and their workspaces near other artists with whom they can experience camaraderie, ideas, information, mutual encouragement, a shared sense of the value of artistic work, and what is sometimes referred to as good 'creative energy.'

*Settings specifically designed to foster creative work**Collectives and cooperatives*

Various types of artists have also attempted to facilitate their own work by constructing and migrating to settings such as artists' collectives and creatively oriented cooperatives. In such intentionally constructed settings they are able to share space, materials, equipment, ideas, perspectives, and information about possible outlets and venues for their work and the same kind of 'creative energy' noted above.

Colonies and retreats

The qualities of some of the most prestigious artists', writers', and musicians' colonies in the United States, such as Yaddo in New York and MacDowell in New Hampshire, also reveal much about the kind of working environments which many, though certainly not all, people involved in autonomous artistic activities desire. In such retreats, artists enjoy 24-h access to designated and protected workspaces in the form of appropriately equipped studios. Lunches are often delivered to the individual cabins or studios in ways designed not to interrupt work. Communal dinners are provided in the evening during and after which residents can socialize, exchange ideas, share work in progress, and generally energize one

another. Relieved of almost all nonwork-related responsibilities and distractions and provided with designated, protected, and well-equipped work spaces, residents are presumably able to focus essentially all of their energy and attention upon their creative work. Though such colonies do not fit the needs of all autonomously creative people, due in large part to the separation from family that they require, and though access to them is sharply limited, the appeal they hold for many autonomously creative people is instructive.

Centers and institutes for creative scholarship

Centers for creative thought and scholarship such as the Institute for Advanced Studies in Princeton, New Jersey and the Center for Advanced Study in the Behavioral Sciences in Palo Alto, California have been designed to offer scholars many of the same features provided by artists' colonies. In such settings scholars are offered: intellectual freedom; designated and protected workspaces in the form of private offices and institutional protection from intrusions by the outside world; access to information in the form of great libraries, internet connections, and other creative scholars and thinkers in residence with whom numerous opportunities for formal and informal interactions are constructed; and, perhaps most importantly, time to think freely and deeply, absent most of the responsibilities associated with contemporary academic life. Though access to such centers is also sharply limited, and though not all potentially eligible scholars could or would want to avail themselves of the full constellation of features offered by these centers, it is once again the case that the benefits offered by residencies at these centers reveals much about the working environments desired by many creative academics.

Creative cities

There is considerable evidence that certain cities and regions of the world have become, for a time, the centers of spectacularly high levels of creativity. Scholars, for example, have frequently cited Athens of the fifth century BC, Florence in the fifteenth century, London between about 1570 and 1620, fin de siècle Paris, Vienna and Paris between the two world wars, and New York City since the end of World War II as centers of certain types of creativity for notable periods of time.

Scholars generally agree that there is no single factor that distinguishes these unusually creative cities from less creative ones, and no single factor that has triggered a common sequence of events leading to their creative efflorescences. However, in attempting to identify some of the factors which have played important roles in the creative periods of these cities, historians have identified several which appear to be highly relevant to some of the needs and challenges associated with creative activity itself.

Informationally rich crossroads

For a variety of historical and economic reasons, these unusually creative cities have tended to be crossroads through which people from multiple cultures passed or to which they came to live and work, bringing with them a steady flow of creative seeds and creativity-relevant information in the form of new ideas, values, knowledge, images, sounds, tastes, tools, ways of thinking, and ways of doing things.

Relatively large, culturally diverse, and histories of interest in high culture

Several of these cities also tended to have been relatively populous, culturally diverse, and to have had histories of interest in and support of high culture. As a result, these cities tended to contain: unusually large numbers of patrons, benefactors, sponsors, and investors who were able to provide creatively-active people with crucial financial support and social recognition; relatively large numbers of people who could be called upon as collaborators and assistants if needed; unusually numerous, diverse and sophisticated 'audiences' (broadly construed) eager for a wide range of new creative products and performances; unusually numerous and varied outlets and venues (e.g., galleries, theaters, literary publications, performance spaces, etc.) by which new creative work could be displayed to potentially relevant audiences and patrons; and numerous and unusually sophisticated 'intermediaries' who were interested in identifying producers of new and creative work and connecting their work with people interested in displaying and disseminating it. The presence of such patrons, potential assistants, audiences, venues, and intermediaries in these cities certainly contributed to these cities' capacities to encourage and support unusually high levels of creative activity.

Attractors of creatively talented and ambitious people

Because of their creativity-fostering qualities, these cities tended to become magnets which attracted creatively talented and ambitious people from across continents and oceans, thus swelling the numbers of creative people living and working in relatively close proximity to one another. Such increased numbers and densities tended to increase the likelihood that creative neighborhoods and enclaves would emerge, that planned and unplanned interactions among creatively active people would occur, and that ideas, enthusiasm, materials, workspaces, cafes, intermediaries, venues and increasingly sophisticated early audience might be shared in mutually beneficial ways. As a result of these processes, of course, such cities tended to foster ever higher levels of creativity and become even more attractive to creatively ambitious people who might gravitate toward them. The fact that recent US census data indicates that specific types of artists (e.g., fine artists, designers, writers) are disproportionately located in certain US cities clearly suggests that processes of selective migration have been and probably continue to be at work shaping this country's creative geography. It seems reasonable to suppose that similar processes are at work in countries around the world.

Creative cities not for all

Most people involved in autonomous creative activities do not, do not want to, and do not need to live in creative cities in order to do their creative work. In the first place, many people simply do not like cities as places to live or are prohibited by practical considerations from doing so. In addition, many creative people do not wish to lose their sense of place, comfort, and belonging by moving to a city. Others do not want to be distracted from their work by the many seductive possibilities that cities offer, to become overly influenced by the highly visible and much-talked-about creative work of other people, or to experience themselves as little fish in big

ponds. Autonomously creative people have also begun to report that new modes of communication and new ways to display of their work made possible by the latest technologies are diminishing some of the creative advantages previously afforded by physical proximity to creative colleagues, potential patrons, audiences, intermediaries, and potential assistants. It should also be noted that many creative people who are attracted by some benefits of unusually creative cities but deterred by others, resolve their dilemmas by locating themselves within easy reach of, but not actually within, such cities.

Caveats

Variability Among Good Creative Environments

Creative people differ from one another in many important respects. They have different personalities, motivational profiles, and work styles, for example. Furthermore, the conditions, settings, and environments conducive to one type of creativity (e.g., writing a novel) may not be most conducive to other types of creativity such as producing a series of multimedia canvases or expanding knowledge of a particular mathematical domain. As a consequence, the exact environmental conditions most helpful to any particular creative person working on any particular project may not be the most helpful to other people working on other projects. Therefore, the ideal macro-environment is presumably one within which people have the freedom and power to construct or migrate to whatever particular environments best suit their individual and perhaps project-specific needs. It is certainly not being suggested here that the multitudinous and varied environments constructed or sought out by free creative agents would share all of the features or serve all of the functions discussed in this article. What is being cautiously suggested here is that many, and perhaps most, of the environments which autonomously creative people would construct or seek out for themselves under such free conditions would exhibit several of the features and serve several of the process-entailed functions identified here. The degree to which this proposition is true, of course, remains to be seen.

Creative Environments Helpful but Not Necessary

What does not remain to be seen, however, and what is extremely important to understand, is the fact that very good environments are neither necessary nor sufficient for creativity to occur. As history shows, acts of creativity can and do emerge from very difficult or even hostile conditions, and as history also shows, creative efforts undertaken in highly supportive environments often fail. Though supportive environments are neither necessary nor sufficient for creativity to occur, it seems reasonable to suppose that they tend to increase the likelihood that creative activities will be undertaken and completed successfully. Establishing or seeking out creatively supportive environments may therefore be analogous to eating well, exercising, and not smoking: while these practices do not guarantee desired outcomes, they generally improve the odds. Given the inherent unpredictability and riskiness involved in creativity, that seems all that could be hoped for.

Glossary

Consensual assessment technique (CAT) Teresa

M. Amabile's method for assessing creativity globally based on the independent subjective judgments of products by expert observers who are familiar with the domain in which the product was made.

Creative Behavior Inventory (CBI) A checklist of creative activities and accomplishments originally developed by Dennis Hocevar, with six subscales: creativity in the fine arts, crafts, literature, music, performing arts, and math/science.

Creative product analysis The process of carefully considering products or product concepts in an objective and unhurried way to examine the underlying characteristics of the product. When the characteristics are understood, they may be used to make rational decisions about the product, and/or manipulated to strengthen and develop the product concept.

Creative Product Semantic Scale (CPSS) The specialized assessment instrument used to gather information from raters about a product or product concept, based on the Creative Product Analysis Model (CPAM) of Susan P. Besemer.

Divergent thinking The type of thinking when many options are generated without prejudgment.

Domain A specific discipline, such as art, business, education, or science.

Novelty The newness of a product; the extent to which it is original or statistically infrequent. This is one of the dimensions or factors of the CPAM, and is the rubric for two facets, Surprise and Original.

Reliability The degree to which an assessment may be depended upon to consistently produce similar results when used by different people in different settings, or by the same people when used at different times.

Resolution When speaking of products, the degree to which the product is valuable, useful, and fits or meets the needs of a problematic situation. This is one of the three dimensions or factors of the CPAM, and is the rubric for four facets, Logical, Useful, Valuable, and Understandable.

Style When speaking of products, style (originally termed 'Elaboration and Synthesis') is the degree to which the product combines unlike elements into a refined, developed, coherent whole, statement, or unit. This is one of the three dimensions or factors of the CPAM and is the rubric for three facets, Organic, Well-Crafted, and Elegant.

Validity A test is said to be valid if it truly and accurately measures what it sets out to measure.

Introduction

The root of the English word create lies in the Latin *creare*, which means to make or to produce. Creation thus implies production, so the term creative product almost seems redundant. We use the term 'product' in a liberal sense to mean expressed ideas as well as observable outcomes (such as a poem, dance, article, cake, or website). The product, broadly defined, is nearly synonymous with creativity.

However, in the history of the study of creativity, the product almost seems to be an afterthought. Noted creativity author Arthur Cropley, recently stated that "thinking about creativity has been hijacked by three of the four Ps: person, process and press, and . . . product has been neglected." Most of the theory and research in creativity has focused on the creative person and, to a lesser extent, the creative process. Such a focus has often eclipsed the study of the very thing that allows us to determine whether a person or process is creative: the product.

Although creativity in products is still underexplored, in the last ten years the total number of studies about products has roughly doubled. A search of the literature from 1965 to

1998 yielded 63 citations; from 1999 to 2009 an additional 67 articles were published. While this search was not exhaustive, the result suggests an increased interest among researchers in studying creative products. Similarly, websites such as *Instructables.com*, *Make* magazine and *Make TV* are indicators of an increased interest among the general public in creating products for fun. This can also be seen in the widespread popularity of crafting and cooking shows.

Evaluation Is Inevitable

It is an inevitable fact that creative products are evaluated, either explicitly or implicitly. Current brain research shows that evaluation is constantly taking place whether or not we are aware of it, or intend to make a judgment. Evaluation is important in education, because students' works of art, writing, and science are evaluated as evidence of learning and aptitude. In business, new product ideas are screened to pick those with the most promise for development and appeal in the market. Works in fine arts and performing arts are subjected to art criticism, music criticism, and published reviews.

The concept of evaluation has been extended to evaluation of ideas (which may be considered proto-products), with the recognition that idea evaluation plays a more important role in the recognition of creative achievement than has traditionally been realized. For example, Cassie Blair and Michael Mumford examined the criteria that people used in appraising ideas. They found that respondents preferred ideas that were easy to understand, provided benefits to many people, and were consistent with social norms; the most original and risky ideas were disregarded. We will return later to the notion that it is possible to have too much originality.

Criteria of Creativity in Products

The common wisdom is that two major components combine to mark creativity in products. The first of these two elements is novelty, originality, or a demonstration of newness in the product. There can be no definition of creativity which does not include novelty, although novelty needs to be considered relative to a given population of products (e.g., products of children should be judged relative to those of other children). It seems impossible to imagine a truly creative product which has no elements of newness.

The second major component which is commonly thought to be important to creativity is the product's value, appropriateness, usefulness, or the extent to which it solves a problem. Without this second criterion as a necessary component of creativity in products, bizarre outcomes such as the senseless muttering of psychotics (which are often highly novel) would be considered creative. There must always be a balance of this second criterion with novelty to elicit praise as creative; too much novelty will cause a product to be rejected as weird or peculiar, even in the arts. An example of this balance is provided by the website *DVICE*, which is devoted to the "wildest and most interesting" new products; however, they make it clear that they also provide a reality check on the extreme novelty of the chosen products.

In addition to these two widely recognized criteria, it has been argued that there is at least one more component. When products are marginally new, or the value that they add is only incremental to the existing standards of a field, they are not usually termed creative unless something in the way that they are made, presented, finished, or implemented adds to the overall product concept. There is something emotional in this third dimension that moves the user, viewer or listener in some way. It evokes a reaction, an attraction, a repulsion, or at least attention of this viewer, the outsider who is evaluating the work. This third component, sometimes called the product's style, elegance, or aesthetic quality, is often missing in the usual definition of creativity in products. The failure to account for the third dimension has caused problems in some empirical studies investigating creativity, where creativity is defined only as novelty, or only as appropriate/useful novelty.

Brief History

The formal psychological study of creativity began in earnest in 1950 when J. P. Guilford stated the need for a rigorous consideration of the subject in the journal *American Psychologist*, and

called for scholarly investigation into the concept. His focus was the creative person, although he briefly addressed creative behavior as the production of ideas. Guilford's structure of Intellect model, in which he described convergent and divergent thinking, greatly influenced creativity studies over the next two decades. Researchers of the 1950s and 1960s frequently did not differentiate between the criteria for judging creativity in personality with criteria for judging creativity in products. However, in his book *On Becoming a Person*, the eminent psychologist Carl Rogers said:

In the first place, ... there must be something observable, some product of creation. Though my fantasies may be extremely novel, they cannot usefully be defined as creative unless they eventuate in some observable product – unless they are symbolized in words, or written in a poem, or translated into a work of art, or fashioned into an invention. (p. 349)

In 1961, Mel Rhodes famously described four strands intertwined in the definition of creativity: the 'Four Ps' of creativity were the person, the process, the environment, or 'press,' and the product. In his *Phi Delta Kappan* article analyzing the concept of creativity, Rhodes stated flatly that objective investigation into the nature of the creative process could proceed in only one direction: from product to person and then to process and to press. However, until the 1990s, little research in creative studies started with the product.

Well-known creativity author Donald W. MacKinnon identified five criteria for creativity in products: the product's originality, adaptiveness (its ability to solve a problem), its elegance and other aesthetic qualities, its transcendence (the ability to transform or transcend reality), and 'realization' (the product's development and elaboration, evaluation and communication to others). He pointed the way to product-related scholarship by his own research on architects identified as especially creative by their peers. Later, MacKinnon guessed that the explicit determination of the qualities which identify creative products had been largely neglected because we implicitly know – or think we know – a creative product when we see it.

In 1980, Larry Briskman argued forcefully for a product-oriented approach to scientific and artistic creativity. He firmly stated that it was impossible to identify creative people or creative processes independently of the creative product and our evaluation of it. He said that creative people and creative processes can only be identified via prior identification of their scientific or artistic products. Briskman contended that we cannot even *describe*, let alone understand or explain, the creative process without reference to the products which are its outcome.

Teresa M. Amabile has employed a product-oriented operational definition of creativity in numerous studies, and her approach has been adopted and adapted by scores of subsequent scholars. She and her colleagues developed the consensual assessment technique (CAT); that is, a product or response is creative to the extent that appropriate observers independently agree that it is creative. In these studies, product evaluations are usually made by expert judges; the goal of such evaluations is most often to observe changes in the level of creativity caused by variations in the treatments of the participant groups.

The most comprehensive work on identifying characteristics of creative products has been carried out by Susan Besemer and her colleagues. In the 1980s, she and Donald Treffinger published a taxonomy called the Creative Product Analysis Matrix (CPAM), with three theoretical dimensions, or three distinct categories for the criteria of creativity. These categories are Novelty, the elements of newness in the product; Resolution, how well the product fills the need or works to resolve the problem for which the product was created; and Style (originally called 'Elaboration & Synthesis'), which considers how the solution is implemented or worked out. Although none of the criteria were original, as they had all been previously published, the construction of a three-dimensional model for identifying creative products was a new approach to the field.

These theoretical approaches lead us to a product-focused definition of creativity. More importantly, they lead to a broader discussion of the measurement issues involved in a product-focused definition.

Measurement

It has been said many times that creativity is in the eye of the beholder; a work's creativity is thus inescapably subjective. The creativity of products can be measured in many ways, and its measurement provides the evidence for creative persons, processes, and environments.

Early measures of creativity, influenced by psychologists, focused largely on creativity as an ability or trait, often assessed by test performance. Early tests focused on fluency, or the number of ideas produced by an individual; this early work was integrated with Guilford's concept of divergent thinking in the 1950s. Note that fluency involves the production of ideas (proto-products); measures of fluency often simply count the number of ideas produced. Sometimes on fluency tests, the ideas are judged for originality, but rarely for any of the other criteria which might be applied to creative products.

A number of researchers have used measures of creativity which indirectly relate to products, some have measured creativity with global judgments of products, and some have devised domain-specific measures. However, few studies have attempted to develop general criteria which can be applied to creative products across many disciplines.

Measures Relating Indirectly to Products

Many measures used by creativity researchers and the general public over the years are somewhat indirect measures of creative productivity: peer and teacher nominations and awards, measures of eminence, and self-reported creative activities and achievements.

Peer and teacher nomination and awards

Peer nomination is a common measure of creativity. With this technique, experts in a particular domain are asked to identify especially creative members of their fields. Presumably, knowledgeable peers of a scientist, architect, poet, or artist who nominate a target person as creative, must to some extent be considering the quality and/or quantity of that person's work. Similarly, teacher nomination is often used to

measure creativity of children. If a teacher can indeed make judgments of a child's creativity independently of judgments of intelligence or likeability, the teacher must be considering (at least to some extent) the child's work in arriving at the judgment.

In recent years awards for creativity in varied fields have proliferated. There are creativity awards for their members in trade associations from audio engineers to manufacturers of corrugated box equipment, and designers of food packaging. The field of advertising alone celebrates creativity with the *One Show* in the United States, giving advertising creativity awards in several categories, awards in Europe (*Epica*), and the *London International Awards* which makes selections from many countries; all of these awards have developed websites. Identifying the criteria used for these awards can be difficult because of the 'we know it when we see it' point of view of many advertising practitioners. Creativity is generally seen as a one-dimensional construct, with effectiveness the counterbalancing factor.

Awards for children's creativity include the *Heinz Ketchup Creativity Award* where children compete for the opportunity to display their works of art on a bottle of ketchup. In contrast to many contests and awards, Heinz has articulated weighted criteria: 50% on creativity, 25% on originality, and 25% on the clarity of the artwork. The website of the *Red Dot Design Award* for adults also specifies criteria including innovation (novelty), functionality, and the formal quality; the jury is composed of design experts. The Invent Now website contains details of the *Collegiate Inventors Competition*; entries are judged on their originality and inventiveness, and the entry must be complete, workable, and well-articulated.

We should point out that these popular attempts to evaluate products use their own idiosyncratic criteria, typically unrelated to research in the field of creativity. They do not often indicate whether measurement issues such as objectivity, reliability, or validity are addressed.

Measures of eminence

Another indirect approach to measuring creative production is to study eminent people. MacKinnon was one of the pioneers of such an approach, using peer nomination to identify 40 of the most creative architects in the United States. Eminence has been measured in other ways. For example, the eminence of artists has been measured by looking at the prices for their work. Traditionally, prices of works by a particular artist tend to fluctuate wildly for several generations after the artist's death, then settle down to some 'proper' place. In this millennium, things changed considerably. Sarah Thornton in *Seven Days in the Art World* observed that contemporary art had reached astounding heights both in the instant evaluation of the auction setting and in art galleries. Until recently, the art of living artists did not sell for astronomical prices, but in the burgeoning economy of the early twenty-first century, the productions of contemporary artists were going at auctions for hundreds of thousands of dollars. Once sold, art works were often quickly re-sold, within a few years again being available at auction, rather than remaining for decades in collections. This fact contributed to the quickly rising value of a particular work, and by extension, other works by the same artist. The phenomenon may not last, but now the traditional technical

and aesthetic values of art criticism for works sold at auction are obscured by commercial selling points.

Starting in the 1970s, Dean Keith Simonton has conducted an impressive research program examining eminent people in several fields such as music and science, usually by analyzing published historical and biographical data. For example, he measured the amount of space devoted to philosophers and composers in different reference works, and in another study, the amount of time devoted to works of various composers by the Boston Symphony Orchestra. In some cases, Simonton directly studied the products of eminent people; for example, he analyzed the melodic originality of composers by measuring the note-to-note transitional improbability (surprisingness) in their works.

Other researchers have also used measures of eminence, generally focused on people with outstanding occupational achievements. The sources for study have included obituaries of scientists from multiple fields, tabulations of the output of classical composers, published illustrations of Japanese print-makers, biographies of modern writers, and many more.

Self-reported creative activities and achievements

Several researchers have used lists of achievements in science, art, literature, and music to assess creativity. Building on earlier work from the 1960s using such criteria, Dennis Hocevar developed a checklist of creative activities and accomplishments. A 90-item Creative Behavior Inventory resulted with six subscales: creativity in the fine arts, crafts, literature, music, performing arts, and math/science. Short forms of the CBI have since been developed. Typically, respondents indicate whether they have won awards in science fairs, have exhibited or performed works of art, have had poems, stories or articles published, have had roles or leads in plays, etc. The total creativity score is based on the number of activities checked or listed, or the reported frequency of each activity. Clearly, creative productivity is being measured, although there is often no indication of the extent to which respondents are being truthful in their self-reports. The CBI has been used in many subsequent studies; for example, Stephen Dollinger found that the CBI was moderately correlated (0.34) with judges' ratings of drawings using consensual assessment. The CBI has inspired the development of other self-report measures, such as the Creative Achievement Questionnaire created in 2005 by Shelley Carson and her colleagues.

Global Judgments of Products

Like the popular press and the contests and awards mentioned above, some researchers have felt that it is not necessary to define creativity in general, nor to define it in products. Often in the creative studies literature, rating creative products is a step intended ultimately to assist in the identification of creative persons, so the definition (or the criterion) is not as important as the identification itself. In the real world, global judgments of the creativity of one or more products are often made, either by a single judge (such as a movie critic) or by a panel of judges. This judgment may involve selecting children for programs for the gifted and talented, or to receive special awards. In some cases, such judgments are made by the assessment of a portfolio of work, but sometimes one single product is judged. For example, high school students who enter the

annual Westinghouse Science Talent Search are evaluated primarily on the basis of an original research paper.

A similar global evaluation is still often used in business to select new product ideas to develop for production. However, the growing influence of the *Product Development Management Association*, which certifies practitioners to assist companies to improve product portfolios, has led more organizations to apply business metrics, technical metrics and sometimes aesthetic metrics to concepts during the new product development process. Businesses are becoming more deliberate about rating their new product concepts, and more explicit in expressing criteria.

Global evaluations are also frequently used in the art field, by art critics or by those making judgments simply on the basis of cost. Some authors, such as Mark A. Runco, have compared global evaluations of creativity in children's art portfolios with judgments made using more specific criteria, such as originality, aesthetic appeal, and technical skill.

Perhaps the world's most influential program of research using global assessments of creativity in products is that of Teresa M. Amabile. In numerous studies, she and her fellow investigators have used expert judges to evaluate creative products using the CAT. Within given parameters, participants are asked to create something on the spot (such as a collage, story, or poem), which is then rated by experts for creativity. The CAT assumes that experts over the course of years have developed their own implicit criteria within their own domains by which they evaluate creative products. Amabile sees no advantage in specifying criteria to be used by the judges in making their evaluations. The inter-judge reliabilities of the creativity assessments have typically been high enough that even if the criteria have not been made explicit, the judges must have been exercising implicit criteria which their experience and discipline-related expertise had internalized, a practice often used in the art world to evaluate works of art.

One drawback to the CAT is that creativity scores can be compared only within a particular sample; no norms can be established for comparisons with products from other samples. However, for many research and educational uses, within-group comparisons are enough. A second issue is that in a few CAT studies, judges' ratings of creativity have been highly correlated (as high as 0.94) with their liking for the products. High correlations with likability suggest that global judgments of creativity may be clouded by preference; for this reason, it is sometimes recommended that aesthetic appeal or technical aspects should be rated as well. Judgments of products made using the CAT have been found to have good to excellent reliability and validity in numerous studies.

Specifying Criteria to Evaluate Creative Products

There is no question that indirect and global measures have advanced the field of creativity. In addition, some authors have examined the specific attributes of creativity in products. Only a few measures have been developed with general criteria applicable to products in many different content areas. More specific types of measures have been developed to assess creative products in specific domains such as art, engineering, chemistry, design, new product development, and education.

Criteria applicable to many domains

An early attempt to specify general criteria was made in 1975 by Irving A. Taylor. He described a scale of product attributes for creativity assessment. In the Creative Product Inventory, he suggested seven criteria for product evaluation: generation, reformulation, originality, relevancy, hedonics, complexity, and condensation.

The most thorough of the few attempts to develop a criteria-based measure that could apply to creative products in many domains was made by Susan Besemer and her colleagues. With Donald Treffinger, she completed an in-depth analysis of the literature of creativity and evaluation in many fields. Based upon a review of more than 90 sources in the creativity literature, and the literature of invention and patents, education, business, and the arts, approximately 125 criteria were identified, and drawn into the three-dimensional CPAM. This theoretical model led Besemer and her coauthor Karen O’Quin to develop the Creative Product Semantic Scale (CPSS). It contained 55 items organized into subscales meant to measure three major dimensions of creative products: Novelty, Resolution, and Style (Elaboration and Synthesis).

Besemer and O’Quin later completed many additional studies taking the broader approach recommended by MacKinnon. Their research focused on the products themselves to identify their characteristics. In 1998, Besemer revised and reorganized the subscales, and has continued to clarify the definitions of the factors and facets. **Table 1** presents the most recent version of Besemer’s three-dimensional model of creative product analysis, which has been refined and changed through many published and unpublished empirical studies using a wide variety of creative products. Several studies have also yielded support for the three-dimensional nature of the CPSS.

Novelty is universally agreed to be important, but some have been uncertain about whether facets of the Resolution dimension are indeed applicable across many domains; for example, it is sometimes said that artistic products are not useful. However, the history of art is full of examples of art which has been useful for religious, ritual, patriotic, or

propaganda purposes. One can also consider the psychological usefulness of art, both to the creator, and to the viewer who may be stimulated by the work of art in several ways, from simple enjoyment to more complex cognitive effort. Another problem associated with Resolution is the concept valuable; does it mean valuable monetarily or conceptually? In empirical testing, valuable has been highly reliable, indicating good agreement about the value of a stimulus product. The Style facets have been questioned because some people feel that such aspects of products are subjective, ambiguous, and difficult to agree upon. However, empirical testing has shown a high degree of reliability in these judgments as well.

Over the years, the CPSS has been extensively tested, both by its authors, and by others who had a need for a structured approach for considering product creativity. It has been used for the purpose of creative product analysis, or a careful consideration of the characteristics of products, typically to improve them. Scholars in such fields as computer-assisted design, textile design, business, education, engineering, and management information systems, have found the instrument useful in their studies. In addition, Global Fortune 500 companies have used the online version in their product development efforts.

Criteria specific to individual domains

Many judging instruments have been developed that are specific to different domains. In the education field, there have been several important efforts. One example is provided by the Student Product Assessment Form developed by Sally Reis and Joseph Renzulli. It contains 15 items which ask judges to rate both individual aspects of the product (such as appropriateness of resources, originality, and logic, sequence and transition) and to make global assessments of the overall excellence of the product. For the nine individual ratings, judges are provided with a summary statement and examples of high quality work to help them establish clear criteria for judgment. Reis and Renzulli’s studies, mostly with gifted children, have yielded good reliability and encouraging evidence for validity of their measure.

Table 1 Revised Creative Product Analysis Model (CPAM)

<i>Novelty</i>	<i>Resolution</i>	<i>Style</i>
The extent of newness in the product, in terms of the number and extent of new processes, new techniques, new concepts included; in terms of the newness of the product both in and out of field	The degree to which the product fits or meets the needs of the problematic situation. How well the product works or functions to solve the problem for which it was created	The way that the product presents itself to the user, viewer, or listener. Its ‘personality’ includes esthetic aspects that can capture the attention of the user and cause an emotional reaction
Facets	Facets	Facets
Surprising: The product presents unexpected or unanticipated information to the user, listener, or viewer	Logical: The product or solution follows the acceptable and understood rules for the discipline	Organic: The product has a sense of wholeness or completeness about it. All the parts fit together in a harmonious or natural way
Original: The product is unusual or infrequently seen in a universe of products made by people with similar experience and training	Useful: The product has clear, practical applications	Well-crafted: The product has been worked and reworked with care to develop it to its highest possible level for this point in time
	Valuable: The product is judged worthy because it fills a financial, physical, social, or psychological need	Elegant: The product shows a solution that is expressed in a refined, concise, and understated way
	Understandable: The product is presented in a communicative, self-disclosing way, which is ‘user-friendly.’	

In the art field, researchers have attempted to specify criteria for evaluating art works. An early example was provided by J. W. Getzels and Mihaly Csikszentmihalyi, who asked fine art students to complete a still-life drawing. Groups of judges (artists and art teachers) evaluated the drawings using three criteria: overall aesthetic value, originality, and craftsmanship or technical skill. More recently, Paul Silvia and his colleagues have also used explicit criteria to assess drawings. In the world of design, Henri H. C. M Christiaans investigated how designers (experts) and lay judges evaluated art works and designed objects. He found that experts judged differently than novices, and, when judging intuitively, had lower interrater reliability.

Examples of product evaluation using specific criteria from the business world have proliferated in recent years. In 2008, the entire final issue of the *Journal of Advertising* was devoted to studies which centered on creativity in advertising, many of which cited the CPSS. As new research builds on the older, sometimes later adapters have chosen to use only one or two of the three dimensions, and have changed or eliminated some items, which may negatively affect both reliability and validity. In marketing, Subin Im and John Workman adopted a ten-item scale from the CPSS; they created a dimension called meaningfulness (a construct including relevance, usefulness, suitability, and appropriateness) that was a better predictor of success than was novelty. This finding is congruent with the results of other studies and the common wisdom that it is possible for a product to have too much newness.

Several studies have investigated creative products in the world of computer science. David Brown considered the usefulness of the CPSS in developing computing systems that may someday actually create products. Diana Horn and Gavriel Salvendy created a measure for consumer products based loosely on the CPSS as well; this measure was later modified for the specific purpose of assessing website creativity.

Conceptual Issues

Four important conceptual issues have played central roles in the theory and research on creativity in products. First, what are the defining characteristics used to evaluate creativity in products? Second, what effects might evaluation have on potentially creative performance? Third, to what extent are the criteria used to evaluate products different across domains (the many diverse settings in which creative products are found)? Fourth, what are the effects of culture upon evaluations of creativity? Each of these questions is more complex than it appears on the surface.

The Problem of Definition

Beginning as early as Guilford's work, and throughout the subsequent years, the critical issue of the definition of creativity has lingered. Sometimes called the 'criterion problem,' it encapsulates an essential operational definition for the field, because the research questions of empirical studies are based on issues of definitions. Jonathan Plucker and his colleagues have discussed this problem several times, in one instance finding that only 38% of a sample of journal articles on the topic of creativity (including those in the top two journals in

the field) included an explicit definition of the term creativity. Plucker emphasized that the definition of creativity must include a perceptible product as the necessary evidence from which creativity can be inferred.

Effects of Evaluation

The fact that the things people make are always subject to the judgment of others can have important effects on the creator. Evaluation can sometimes inhibit the maker's best efforts. For example, Feirong Yuan and Jing Zhou found that students who were expecting to be evaluated generated fewer novel ideas (the judges were given a definition of novelty). But, under the proper conditions, evaluation can encourage the maker if the focus is descriptive and allows the creator to adjust his product to better achieve his goals; Yuan and Zhou's study showed that idea appropriateness was enhanced when the participants expected to be evaluated.

Although it must be acknowledged that products will be judged, the manner in which they are judged can be very important to the future efforts of artists, inventors, and others who are bringing new works into being. Much too often, the products created are judged in a quick, superficial way, without the kind of objective analysis which could benefit their creators and the field at large. The lightning speed evaluation of the art auction is a prime example; if a work of art does not meet the sellers' reserve (the lowest price at which a work will be sold) it is removed from the auction. It may later be offered again, held, donated to a museum or otherwise removed from the market, but the initial removal can have a devastating effect on the artist's reputation – especially because the auction selling time of any particular work of art (even masterpieces) is mere minutes.

Hasty evaluation is not limited to the art world. It can affect creativity in schools and in business. In schools, the standard typically exists that a student's creation must be a bit different, but not too dissimilar, from others in the same category. Sometimes businesses get stuck in the same paradox. While looking for that critical creative spark, there is a substantial pressure to select new product ideas which are product line extensions rather than the riskier, but potentially more profitable, truly novel product ideas. Note the frequency of movie sequels! While most new products are actually refinements and improvements of existing products, it is worthwhile for companies to develop a product portfolio which includes a strategic mix of new product offerings ranging from the evolutionary to the revolutionary.

Although it may seem that the arts would be more accepting of shocking novelty, art is judged within the framework of criteria for technical expertise which reinforce the standards of the culture and the time. Thornton maintains that nowadays some artists reject the traditional values of technical craftsmanship and are more interested in conceptual art dissimilar from the work of even the recent past. However, novelty for its own sake is still rejected by the art establishment. The truly novel 'outsider art' of unschooled artists is often (but not always) ignored in the mainstream art world. As we have seen, whether we are talking about highly novel products by children, new commercial products, or even art products, there is a fine line between having an attractive new twist and being

so far out that the product is rejected by powerful judges: teachers, consumers, or critics.

Are Expert Judges Needed?

Another issue related to evaluation is the question of whether or not untrained judges can make informed and valuable judgments. Besemer and Treffinger stated that there was little expectation that untrained judges could adequately evaluate works in areas where they had little expertise. An interesting paradox is that in subsequent empirical studies using the CPSS (based on their work), it was discovered that when employing a standard judging instrument with explicit criteria, there was great reliability in the evaluations of creative products made by untrained judges.

Numerous other authors have addressed this question. Amabile and the many other researchers using the CAT have emphasized that expert raters are needed. However, it is possible that because the CAT depends on judges having developed implicit definitions of creativity in their own fields, its use will always demand expert judges. When the criteria for judging are made explicit (as with the CPSS) and/or judges are trained, the need to use expert raters may become less important.

A second factor related to whether expert judges are needed is the extent to which the domain requires specialized skills or knowledge. Only experts in particle physics would have the knowledge necessary to be able to judge the creative work of a particle physicist.

Additionally, it seems likely that the more 'cutting edge' a product is in a specific domain, the more likely an expert judge will be required. For consumer goods, lay judges (consumers themselves) are an important part of the testing cycle of the new product development process. Some authors have suggested that judgments are more likely to converge with regard to 'mainstream' products, but less likely to be similar regarding extremely innovative products in particular domains.

It is also possible that professionals, although capable of making a product, might be unreliable or inaccurate when judging it, perhaps because they rely on high-level, esoteric, or idiosyncratic standards. For example, Mark Runco and his colleagues found that professional artists were relatively insensitive to differences among artworks produced by nonprofessionals. Advertising researchers have confirmed that expert judges' ratings do not always concur with those of consumers at whom the advertising is aimed. It seems useful to use expert judges in preliminary in-house testing of commercial products, but to expand to testing with the intended audience as products move through the product development cycle. When experts are available the CAT has been shown to be fruitful. But when testing products in real life settings with consumers, more explicit criteria can be useful, such as those of the CPSS.

Different Domains

Another issue in the study of creativity in products is an often implicit assumption that the discoveries about product characteristics in one discipline are unique to that field. There are so many different fields of creative production, including the arts, sciences, business, and education, that practitioners in each of these fields assume that their worlds are unique and need

special ways of evaluation that are exclusively theirs. This assumption encourages the development of specialized judging instruments which may limit the ability to make comparisons across disciplines.

It is true that all areas where judgments about creativity are being made have their own unique, often technical, criteria or standards of quality. For example, the website of the *Center for Universal Design* must focus on very specific criteria needed to design or redesign products for individuals in wheelchairs or with other diverse abilities. The designers of thermal clothing for fishermen must consider technical criteria including sweat absorption, ease of movement, resistance to sun and salt, and soiling propensity. Clearly, at this level of specificity, there is little overlap among domains even in the business world, let alone in the broader realm of creative activity.

However, at a slightly higher level of abstraction, it is possible to deduce similar schemes for analyzing and discussing the products of differing disciplines. Making comparisons at this level would allow different types of products to be compared, facilitating the general development of more widely applicable standards of judgment. For example, the CPSS has been used successfully with products ranging from t-shirts to magazine advertisements, and from medical equipment to cell phones.

Effects of Culture and Society

As many have said, creativity is in the eye of the beholder, so creativity judgments are subjective. Therefore, these judgments will be affected by the society and the time period in which they occur. Among the cultural factors that may play a role are social institutions, creative ideologies, economic support for creators, patronage, marketing outlets for creative products, and societal values about appropriateness. Even for research scientists (whom we stereotypically think might be isolated from this kind of pressure), the laboratory social environment, including power, independence, and communication issues, can affect creative productivity. One of the best-known theorists discussing this topic is Mihaly Csikszentmihalyi, who has made a strong argument for considering the effects of society and culture upon creativity. Simonton is another noted author who has addressed sociocultural factors, especially in the recognition of eminent people, including composers, psychologists, inventors, political leaders, and scientists.

Some people have suggested that because standards of evaluation are not absolute, researchers may as well abandon any attempts to specify criteria for creative production. We disagree. Although the varying effects of societal and cultural standards make the task more difficult, the notion that evaluation of some sort takes place is universal. Cross-cultural studies can identify similarities and differences in product perceptions across nations.

Relationship to Inventions and Innovations

Our purpose is not to examine the extensive literature on invention and innovation because they are addressed in separate chapters within this encyclopedia. The innovation literature tends to be process oriented, and the invention literature tends to focus less on the product itself and more on the marketing issues which affect the success of the product. To illustrate the market focus of inventions, the website

of the *Edison Awards* lists the nomination criteria, which include marketplace innovation, marketplace success, market structure innovation, and societal impact. However, there is an important overlap in definition: the website of the *US Patent Office* defines an invention as being new and useful, both of which are important criteria in the creative product literature.

The website of the *Innovation Institute* describes how the National Science Foundation, through its Innovation Centers Experiment, supported the development of a commercial innovation evaluation system. Prospective inventors take their ideas to a center to be evaluated. Gerald Udell pointed out that it was necessary to provide training and close supervision for evaluators at the centers to develop the competence necessary to make informed judgments; untrained evaluators were almost uniformly positive in their judgments. Udell also stated that it was necessary to formalize the criteria used by trained evaluators because they had been making inconsistent and unrealistic decisions. The website mentions 45 criteria, some of which evaluated the product itself, but most dealt with practical marketing issues such as legality, safety, business risks, market acceptance, etc.

Looking to the Future

When considering creative persons and creative processes, it is clear that even extremely creative individuals vary on the creativity shown in any particular work. Some products may be more or less creative because the makers were working in a new or a well-learned domain, were more or less successful that day at expressing their creativity, or had more or fewer restrictions on their work at the time. Makers may have been feeling well or ill during the time that they worked on the product, or they may or may not have been affected by environmental factors such as heat, light, or air quality. Because of the variance in the creativity of any particular product, it seems risky to expect a single product, made only as a result of an unexpected assignment on a creativity test, to be representative of a maker's usual level of creativity.

Likewise, few would expect a creative person to be equally creative in all domains of his or her life. Some exercise their creativity mathematically, some artistically, and some in business. Creativity tests which pose a creative task are most valid for those whose creativity is manifested in the domain which is being tested. To be evaluated poorly in the creativity shown in a drawing task, does not mean that one's mathematical or culinary creativity has been adequately assessed.

Another caution exists because of what we know about the process of creativity. Creativity may involve divergent thinking and the development of many ideas before the completion of the task. Creativity tests which demand that the first and only product of the exercise is judged for its creativity do not benefit from this awareness. The instruction, "Do this task now, and Be Creative!" can be intimidating to people who prefer to take their time and adopt a more experimental approach. Again the work produced may not be representative of the maker's usual creativity. A portfolio approach to assessment of creativity, in which a person's best works are evaluated, seems much more promising.

These cautions suggest the need for returning to the old questions posed by MacKinnon, "What are creative products, and by what qualities are they identified?" There remains a strong need, both in research and in the real world, for reliable and valid guideposts for identifying creativity in products. A great deal of progress has been made in the past decade, but researchers must still be persuaded of the importance of product measures of creativity, whether indirect, global, or facet. Further work with product measures such as the CAT, the CBI and its successors, and the CPSS will help advance the field, because as MacKinnon said, the study of creative products is the basis upon which all research in creativity rests.

Finally, in order for the field to advance, we need to develop a common language and common definitions to facilitate communication across different domains. Seeing similar criteria in the creative products of scientists, artists, dancers, chefs, schoolchildren, and entrepreneurs will help us to know the true meaning of creativity.

The Creative Sector and Class of Society

S Cameron, University of Bradford, Bradford, UK

© 2011 Elsevier Inc. All rights reserved.

Glossary

Bobo Bourgeois bohemian.

Class conflict Dispute between classes founded on economic inequality and opposition of interests.

Creative destruction Constant process of old products and services being replaced by new ones.

Creativity index Measurement tool, constructed by Richard Florida, to rank cities in terms of their creativity.

Malevolent creativity Use of creative ideas to inflict death and suffering on other individuals such as, for example, in acts of terrorism.

Postindustrial society Notion that ideas have become more important, social and economically, than physical acts of production.

Introduction

This topic involves an irksome amount of nitpicking about the meaning of words. Even assuming that we know what society is and agree on it, there are persistent problems of defining the 'creative sector and class of society' thanks to the work of Richard Florida. Let us begin with the simple premise that creative means being involved in the production of ideas rather than the routine production of material goods. Avoiding, for the moment, the issue of whether the ideas produced are new, original, worthwhile, etc. The routine production of material goods depend on the production of ideas in many cases. No one would claim that the worker who puts the latest lifestyle changing gizmo in its sales box for despatch is being creative in the 'creative class' sense of the word. This worker is, of course, having their job and income created in some sense by the creative workers whose ideas lead to the development of and marketing of the gizmo.

Turning to the use of the concept of class, we identify this idea with Marx and subsequent sociological thinkers. In view of this, a distinction needs to be made between a class as merely a collection of similar entities and a class as something which has social and economic meaning as a category. The Marxian concept of class falls in the latter category. In Marxian terms, the concept of class was intimately linked to the notion of opposition between classes who had mutually contradictory interests. They were thus destined to be antagonistic to each other. In contrast, this is not the nature of class in the use of the term 'creative class' which becomes rather part of a 'win-win' world where the creative class is the source of benefits to all. This will be expanded on further below in the section on critiques of Florida. The broad implications of identifying a class are that it contains a group of occupations that have something in common in terms of work. Also, the members of the class are likely to share ideology and pursue common goals. Apart from sharing occupational interests and ideological interests, a class might also be distinguished by shared traits in the consumption of goods and leisure activities. Aspiring to the leisure/consumption traits of a different class is one way people can attempt to escape from their economic class.

If one believes in the creative class concept it is possible to argue that there has always been a creative class but its

importance has been massively increased by technological developments. That is, physical production of products decreases in importance whilst production of ideas increases in importance. Florida, in his *Atlantic Monthly* article of 2009, stated:

The economy is different now. It no longer revolves around simply making and moving things. Instead, it depends on generating and transporting ideas.

Within the debate inspired by Florida, there is a further profusion of terminology such as the 'culturepreneur' and the 'bobo' – bourgeois bohemian. David Brooks, described by Florida as "a conservative critic," aspires to attack Bobo society as something inherently hypocritical and vacuous due to its incoherent reconciliation of the opposing concepts of conformity and radicalism. That is a reconciliation of creative values and business values. He argued that Bohemian values 'rule' in America today and have been absorbed by the corporate establishment and used to sell goods. Bobos are start-up capitalists, or visionaries like Bill Gates and Jeff Bezos. According to Brooks, Bobos love oxymoronic concepts like 'sustainable development,' 'cooperative individualism,' or 'liberation management.'

The notion of a bobo enshrines the dual consumption and production aspects of class. The historical notion of a bohemian class is one of a distinct antimarket nature. The mythical Bohemia is where 'artistic with a capital A' types of creatives hang out and shun the mores and conventions of the working class, the capitalists, and so on. The traditional Bohemian class does not figure prominently in Marx or other economic sociologists. This is because it would have no significance other than as a form of parasite begging, stealing or borrowing from the other classes. In terms which were dismissed by Adam Smith in *The Wealth of Nations*, but later resuscitated by some economists in the 1970s and 1980s, they are 'unproductive labor.'

In developed welfare capitalism, there has been an unintentional use of the unemployment benefit system to fund creative (in the bohemian sense) class activity. A prime example arose in the United Kingdom (being a nation with an atypically generous benefit system) in the late 1970s with the 'punk rock' revolt against the embourgeoisement of the (supposedly)

alternative class activity of 'rock and roll' music. The leading participants had colorful names not primarily for the purposes of distinction but in order to facilitate the maintenance of their benefit payments by making detection of paid work (as an entertainer) more difficult. It could be argued that the creative class activity, thus funded, revolutionized many areas of the economy and society. It did this by displacing the monopoly power of entrenched capitalists and a creative class that had become stagnant in terms of recycling activities that were once new and original. As Brooks would have it, the would-be revolutionaries eventually become integrated and thus eventually arrive at being 'Bobos' – bourgeois bohemians. Thus it appears that business sector values ultimately dominate those of the creative sector.

The contemporary notion of the creative class is a logical consequence of the move to the idea of a "Post Industrial Society" as posited by the sociologist Daniel Bell in the 1970s. He saw a shift from manufacturing towards theoretical knowledge as the source of innovation and policy formation for society. Other exponents of the postindustrial thesis have drawn further conclusions such as the demise of the role of the working class as agents of social change (as had been posited by Marx) and/or the rejection of materialist profit-oriented culture by young people. The agents of change are the creative class who possess the theoretical knowledge which society needs. They are no longer the mere servants of the capitalist class, like industrial chemists and electronic engineers, but now include anyone who is capable of generating ideas which may bring about change.

That agents of change exist, and that they might be deemed to be creative, can be accepted as an idea without it necessarily implying that they form a conceptually meaningful class or sector. The idea that they do form a meaningful aggregate currently attracts debate primarily due to Richard Florida.

The Work of Richard Florida

As indicated, the current treatment of the creative class fits comfortably into the postindustrialism thesis of Daniel Bell and others. The prominence of the creative class idea at present is largely due to the promotional efforts of Richard Florida. A large part of Florida's impact is due to his promoting the idea that governments should actively seek to use expansion of the creative sector to spur economic growth. He has recently even taken (BBC Radio 4) to claiming that the British Government should talk to Elton John and the Rolling Stones about how to reinvigorate the economy. This is premised on the idea that these creative (thus 'not business') people produced massive wealth which tends to ignore the fact that business entrepreneurs (and mainly multinational corporations) generated their incomes by exploiting their potential as products and product deliverers.

Precursors

The role of cities

As with all gestalt shifts, the work of Florida did not arise from a vacuum. It is particularly linked to the role of the city in economic and social development. Florida himself continually

gives credit to the work of Jane Jacobs on the economy of cities. Looking at Jacobs work now, it is striking how little (practically no) mention is made of any kind of creative class. Even when speculating on the future growth of cities, at the end of the book, Jacobs does not draw on the work, which was by then appearing, from Chicago economists, on the role of human capital and knowledge in economic growth and development.

However, the analysis is firmly centered on the importance of classes in generating the growth of cities. The growth of cities is seen as the key feature of the growth of economies. Jacobs argued that manufacturing would decline in importance to be replaced by services. This is therefore another tributary in the postindustrial society literature. She discussed Marx and class conflict in Chapter 8, "Some Patterns of Future Development." She argued that class conflict has not arisen between workers and capitalists nor has it been characteristic of more industrialized and developed nations. Rather, class conflict will be found between emerging sectors of economic activity and those entrenched sectors which stand to lose their position. If this is to be more than just a conflict of interest and, instead, become a fully-fledged class conflict there would need to be shared ideology and some degree of collective action within those designated as being in a class. There would also have to be a degree of inertia or laxity on behalf of entrenched interests.

Looking at mass publishing, for example, this does not generally seem to be the case. Large-scale newspapers and magazines have embraced internet publishing and integrated it into their operations. It is thus difficult to see that there has been much class conflict within the sphere of news and general interest media. Likewise the class conflict in distribution media (music, films, computer games) has not been between 'old' and 'new' notwithstanding that new media is the locus of David Brooks' iconic Bobo figures. Rather conflict here has been centered on those seen as stealers of ideas usually represented as pirates. Conflict occupied only a small portion of Jacobs' work. It is fair to say that it has taken up relatively little place in Florida's work where the main conflict seems to be between himself and his critics.

In more recent times, there have been attempts to reposition the dialogue in urban development in terms of the shift from materials-based production to idea-driven production. For example, Joel Garreau, in his book *Edge City* based on interviews of well-paid white-collar workers, identified the phenomenon of the gentrification of districts that were on the (physical) edge of cities near busy roads and decaying industrial sites. The revival of these areas and the consequent property boom, due to incoming professionals, tended to make it difficult for the genuine bohemian old-style 'creative' to live there. This would thus seem to create some sort of class conflict, as those who made the neighborhood attractive in the first place find it hard to be able to afford to live in it. Although Garreau identified the 'funky neighborhood' as an important social development he did not go on to categorize his lawyer and business interviewees as members of a creative class.

The knowledge economy

Although it has not rapidly percolated through to intermediate economics textbooks, the developing importance of the role of ideas in production has been gathering pace as a subject in various areas of economics. As mentioned above, this began in

the 1960s with Chicago economists who positioned human capital at the center of the growth process. Economists also became interested in the importance of information thus resurrecting the old cliché that 'knowledge is power.' The development of interest in large corporations highlighted the association between large research and development expenditures and corporate growth. Research and development is the corporate enshrinement of creativity as research involves initiating either a new product or a new process (in the sense of new arrangements of existing methods) and development involves bringing it to the market. However, within the discipline of economics, the sector/class identity of research and development personnel has been somewhat shadowy. In some theoretical models, the group of people who supply research and development ideas were not identified as a specific sector of the economy at all. Rather, they were left as a floating set of individuals somewhat like the archetypal 'mad inventor' pursuing endless patents from his or her garden shed. Outside of mainstream economics, the rise of meritocratic groups of scientists and researchers was noted by industrial sociologists and maverick economists like J. K. Galbraith in his *New Industrial State*.

Florida

The impetus for Florida's work comes from the changing nature of cities which find themselves saddled with areas of degeneration due to the decline of the manufacturing culture. In a market society, there is no automatic balancing mechanism that harmonizes the class structure of a city or region. A city could end up, through unregulated market processes, with very few of the creative class residing in it. According to Florida, this would lead to its decline which could be reversed by injecting a creative class. A city could survive as a parasitic server of noncreative services (cleaning, waste disposal, filing) to a nearby city which is expanding due to its creative dynamism. In such a context, it may still nominally and legally be a city but conceptually will have declined to be a shadow or satellite of the 'host' city. In social and symbolic terms, it will not really be a city because it has no vitality. Logically, it would seem that this does not mean that it could not be economically successful as an exporter of goods and services even though it has little or no creative class. Such a city is still distinct from a suburb as a suburb is seen as a place of residence rather than a place of work.

Florida asserts that cities can be regenerated by expanding the creative class/sector. This is based on examination of 'empirical' evidence of various types including anecdotal inferences from descriptive statistics and most problematically inferences from regression equations. These equations are used to impute a figure to the impact which changes in the size of the creative class (proxied by the degree of presence of a gay population in the neighborhood) have on the economic development of a region.

Florida's Definition of the Creative Class

Marx defined class in terms of ownership of physical and financial assets. A creative class, by extension of this, could possibly be defined as ownership of ideas. Florida's definition is not strictly this kind of transference. The Bay Area figures

prominently in Florida's work such as his book *The Rise of the Creative Class*. San Francisco is the prototype for the kind of city Florida celebrates. It shows up with Austin and Seattle at the top of his 'Creativity Index.' Florida divides the Creative Class into a smaller subset – the 'Super-Creative Core' – which includes the fields of computers and math, architecture and engineering, the social sciences, education, arts, design, entertainment, sports, and media. This core group – which already represents a very generous definition of creativity – constitutes a little under 12% of the workforce. The widest definition covers 'creative professionals,' encompassing management, business and financial operations, law, health care, and high-end sales and management. This brings the creative class up to around a one-third of the United States labor force. This includes "fashion designers, musicians, film directors, artists, and – yes – psychiatrists."

Florida (2009) said:

The economy is different now. It no longer revolves around simply making and moving things. Instead, it depends on generating and transporting ideas. The places that thrive today are those with the highest velocity of ideas, the highest density of talented and creative people, the highest rate of metabolism.

Government Policy Inspired by the Creative Class Idea

There can be no doubt that the notion of a creative class figures prominently in the thinking of the major liberal democracies. In the United Kingdom, this showed itself in Labour Prime Minister, Tony Blair's promotion of the creative industries to the center of attention. This has been carried on by his successor Gordon Brown. For example, *Creative Britain: New Talents for the New Economy* published in 2008 has the following contents:

1. Giving all children a creative education.
2. Turning talent into jobs.
3. Supporting research.
4. Helping creative business grow and access finance.
5. Fostering and protecting intellectual property.
6. Supporting creative clusters.
7. Promoting Britain as the world's creative hub.
8. Keeping the strategy up to date.

This document consists almost totally of marketing-speak. Its overwhelming aim is to promote Britain's creative identity as part of the 'brand' of Britain which will ensure success in global competition. Curiously, Chapter 7 only identifies the areas of ceramics and textiles (the former of which has, ironically, lost one of its most prestigious firms to bankruptcy in the current recession), some media companies (EMI, BBC), and a bit of architecture. EMI is essentially a multinational firm sitting on a legacy of international property. It is difficult to see what is creatively 'brand Britain' in its portfolio. The legacy of the BBC represents the precise opposite of the spontaneous emergence of creative class output in a free market. That is, its collected works represent massive state subsidy from enforced payments by taxpayers.

Movements towards stronger copyright protection (explicitly dealt with in Chapter 5 in this document and found all over the rest of it) of unauthorized internet transfers/use of creative works is further evidence of government support for the

importance of creativity in the economy. Subsidy in the United Kingdom has come via NESTA which typifies the win-win tendency in seeking to finance creativity out of lottery money. The notion that the creative sector can drive economic activity has also been embraced by local governments who have generated an explosion of festival activity where the justification of the festivals has been that they are cultural and thus generate a magnetism effect.

Critiques of Florida

There have been a range of negative reactions to the idea of a creative class. Various questions have been asked. Are we dealing with genuinely meaningful changes in social structure or just changes in the words used to describe relatively unimportant changes or in fact no change at all? Are we entitled to say 'so what?' to the notion that growth and creative class magnitude go hand in hand? Does the notion of creative class help explain relevant phenomena in some way that could not be done by other ideas? Aside from the explanatory issue, there is the matter of policy relevance – does paying serious attention to such ideas enable us to better solve important problems?

It is convenient to divide the criticisms into four main areas.

Perversion of the Concept of Creativity

Is Florida really talking about creativity when he describes the creative class? This has been disputed particularly by people who like to think of themselves as being creative in the artistic sense and are feeling demeaned by the admission of psychiatrists, and the traditionally unbohemian class of businessmen, into their ranks. For example, an internet posting by Karrie Jacobs argued that the cities which are vaunted as high points of creativity are in fact anything but. She said:

One cool business district looks pretty much like the next, just the way one suburban mall looks pretty much like the next. And once you start thinking about creativity in terms of class, hipness as a monoculture seems like the inevitable outcome.

This harks back to the notion amongst creativity researchers that the key characteristics of creativity are novelty and the attendant element of originality. Something which is not novel and surprising to some extent might tautologically seem to be devoid of creativity. However, surprise cannot be maintained indefinitely as exposure to novel events and ideas progressively diminishes the element of surprise. Painting in the style of Picasso and playing guitar in the manner of Jimi Hendrix are, by now, yet more established brands woven into the fabric of capitalism.

It follows that attacking 'identikit' neighborhoods, where the creative class drink their designer coffees and plan their marketing strategies, may be a displaced 'category mistake' argument. It might be useful to enter into the comparison with MacDonalds Hamburgers at this point. Once upon a time, the opening of MacDonald's was a creative act by mere dint of the fact that no one had thought of it before. It was thus original not only as a business concept but as an idea in general. It is not impossible for individuals to be creative in a MacDonalds or a Starbucks. They could, for example, be

magnificently creative on a laptop they have brought with them. However, the ethos of such corporations is not conducive to user creativity as its aim is to rapidly throughput customers all taking identical products. From time to time it may innovate, in response to identified demand shifts, in its provision of products. The aim of this is to reestablish the fundamental core business concept, not be creative in the usual sense of the word. The Austrian economist, Joseph Schumpeter, in a sense, endorsed the notion that MacDonalds is part of the creative sector in his analysis of the 'gale of creative destruction' that is typical of the capitalist process. That is, he sees new entities which replace existing entities in their field as 'creatively destructive' because they are adding value by destroying the thing they replace. This may not entirely cohere with the notion of creativity espoused by creativity researchers.

The core definitional problem in the 'is this really creativity?' argument is that it would appear that the term creative is now being applied to *absolutely anyone who is some kind of problem-solver who does not work with materially tangible goods*. (In this definition, I am absencing plumbers, electricians, and computer repairers from the creative class.) Advertising geniuses solve the problem of selling people things they do not really need and psychiatrists (hopefully) solve deep-seated emotional crises. Hence they graduate into the creative sector. The prevalence of seeing creative as 'almost any' problem-solving is further encountered in the discussion on malevolent creativity.

If the argument that the term 'creative' has been wrongfully subverted is convincing, there needs to be some reconstruction of what being creative does 'really mean.' If it is not just problem-solving for the furtherance of the capitalist system then it would seem appeal has to be made to creativity as something which embodies higher social, spiritual, or humanitarian values. This is a notion of creativity which has tended to drop out of sight during the creative class debate which has been focused rather on the money-making potential of creativity. That is, modern creatives are not generally viewed as someone with a 'higher' vocational calling. Rather, they take on the mantle of entrepreneurs. This is particularly evident in the visual arts world where careers are built on shock and novelty rather than intrinsic value.

Source of Value Fallacy

One might claim that Florida's ideas are a resurrection of the 'source of value' fallacy enshrined in the pioneering economic work of the French Physiocrats of the eighteenth century. Histories of economic ideas present the French Physiocrats as somewhere on the cusp of prescientific economic thinking. Their major failing was the attribution of the cause of economic wealth to a single source, agriculture, from which all other activities were derivative. The esteem in which Adam Smith's 1776 Wealth of Nations is held is, in some part, due to his overturning the attempt to establish single factors as 'causes of value.' Single factor value theories would have a renaissance in the works of Ricardo and Marx where attempts were made to ascribe all value in goods to their labor content.

Florida would not be so ridiculous as to try to claim that *only* the creative class generates value. Nevertheless, there would be little point to the song and dance he makes about its importance, if it was not to be concluded that it is the

primary determinant of value. This is backed up by some of the quotes given above. The major critique of all uncausal explanations is that they overlook the importance of co-operation and synergy. The creative sector is only able to be important when it is properly accompanied by the relevant factors of production from other sectors. It therefore becomes problematic to attempt to separate the productive contribution of different sectors using aggregate statistical analysis on data which was not designed to test any such hypotheses. In the terms used by economists, we face the problem of separating the marginal product of the creative class from that of the labor or capital classes.

Shortage of Convincing Empirical Evidence

Ideas which gain popular currency can have a variety of relationships to empirical evidence. They may not rely on any support from it whatsoever. They may be thoroughly and rigorously supported by it. Or, they may have some tangential and ephemeral support which acquires mythical and rhetorical status amongst supporters. Critics of Florida would assert that the last situation is the most apt description. Florida's empirical evidence is of two types: broad casual assertion and causal analysis of relationships. The former is shown in his construction of indices of creativity and the latter in his attempt to link measures of the bohemian nature of an area to its economic success. The use of data on the 'gayness' of an area has been something of a red herring in this matter. Florida has claimed that some attacks on him have been due to people thinking he is gay (which he is not) or homophobia in general. This can not be said of the strong critique by economist Daniel Glaeser which is based on the traditional statistical philosophy of testing the robustness of the point estimates and confidence intervals, of any estimated relationship to modest changes in the parameters of the investigation. Glaeser concluded that Florida's estimates are not robust. Even if they were, there is still the perennial causation problem that prosperous areas may have attracted creative classes and not the other way round.

Total Absence of Any Kind of Class Analysis

Although the derivation of the idea of inevitable class conflict, from the existence of classes, is no longer taken seriously by most social scientists, the ideas of Marx and Weber are still important if the notion of a 'class' is to have any useful meaning. This requires both shared economic interests and shared social behavior. The latter may reinforce the former. Consumption interests, such as tastes in literature and music, may help the formation of a bourgeois bohemian, or other, type of ideology which helps sustain the dominance of the class in society.

As indicated previously, Jane Jacobs provided a fleeting and unconvincing analysis of class conflict and Florida has tended to follow this. Marxian class conflict was expected to end in bloody revolutions where the exploited eventually paid to the hegemony of the exploiter. This is only one possibility and one that seems unlikely in western democracies. Here, it could be argued, conflict is meliorated by the fact that the creative classes are seen as not being exploitative at all. In the terms used by modern American economists they are opportunistic 'rent seekers' who find ways of encouraging transfers of income that exceed their productive contribution in their direction.

One such bunch of 'creatives' is found in the advertising industry whose role is to intervene in the competitive process to redistribute profits between existing products. It also encourages the expansion of consumption beyond what the consumer wishes to spend. Florida could be seen as an ideologue who is essentially an apologist for capitalism, rather than a serious social analyst. In this vein, he can be compared to economists like McCloskey and Klammer who attributed one-quarter of US GDP to persuasion giving us a nice ballpark figure in a comparable zone to Florida's 30% of the economy in the creative sector' claim. They argued that persuasion (such as advertising) is a good thing which improves human well-being.

Wider Issues of a Creative Class or Sector

The prominence of writings about the creative class/sector has occurred at a time of unprecedented global expansion. This has now unfortunately come to a halt in the guise of the 'credit crunch.' As house values tumble, unemployment rises, and bankers sink into disgrace one is entitled to ask where the creative class fits into all this. Is it the cause of the problem or will it save the day? In general discussion, blame has been firmly placed on the shoulders of bankers as they were at the decision-making helm when the trouble occurred. However, in a deeper analysis of a holistic nature *we* might lay the blame on the underlying nature of capitalism. A parasitic creative class would be symptomatic of the exploitative nature of capitalism.

Florida's recent work stops short of the counter-claim that the creative sector will solve the current problems of the economy but notes that the creative sector is doing better, during the global recession, than other parts of the economy. Even if this is true, in a wider arena than the data he consults, it is not clear that it says anything very much. A class conflict analysis would suggest that this may merely reflect the exploitative hegemony of the creative class which makes them better able to protect themselves.

As will be clear by now, the popularity of the creative class idea carries with it upbeat notions of economic and social benefits. It would seem absurd that anyone would want to stifle creativity lest it lead to bad, dangerous or catastrophic ends. The obvious counter to this is that Hiroshima and the threat of the end of the world due to nuclear reaction are products of allowing human creativity full reign. Two things might be said against this. One is that the problems are not the fault of the creative sector per se but the fault of others, as being creative does not thereby render one a moral guardian of the universe. The second is that these problems are problems of the scientific sector, which might be seen as different from the creative sector, even though creativity, in the literal sense, is involved.

The *Creativity Research Journal* carried a special theme in its issue for April-June 2008, on the topic of 'Malevolent Creativity.' This was not concerned with the aforementioned dangerous scientific research issue but rather the creativity of those involved in acts of crime and terrorism. The paper by James and Drown looks for lessons from 9/11 and the transportation of hazardous materials by truckers. This article and the other commentaries in the *Creativity Research Journal* are

framed in the context of the normative assumptions of the traditional discussions of the creative class. That is, they are looking for useful policy conclusions in the shape of improving ways to prevent malevolent activity.

The key features in the analyses of malevolent activity are the same as those in the general analysis of creativity. Malevolent acts require problem solving and thus call on creativity in a broad sense. In this vein it has been argued that 9/11 was certainly a creative act along with other unsavory acts, including the strategic activities of terrorist organizations. For example, attention has been drawn to the IRA (Irish Republican Army) as being extremely creative in their ability to use readily everyday items as materials for reliable and effective bomb-making devices. There are many ways to blow up a building for example. Some will be more successful than others and some will be more ingenious. If the malevolent actor gets direct benefits from displaying ingenuity then they may prefer the more creative, but less efficient method, to a tactically superior one.

Not all creative acts that fall outside the normative framework endorsing benevolent creativity would necessarily be entirely malevolent. The most conspicuous examples of this occur in the areas of digital downloading. The landmark events in this have been the Napster and Pirate Bay trials. Ostensibly these cases have reflected the triumph of the creative class, supported by the state, over a parasitical class which attempts to live off their labor. That is, the kind of class conflict speculated upon by Jane Jacobs. However, we may note that industry insiders are now admitting that the handling of the Napster case was a mistake and that they should, at that time, have seen that the problems faced were a wake-up call to arrive at a new business model to deal with changing technical conditions. Coupled with this, it is reported that since the Pirate Bay defeat, the site has been sold for a large amount of money thus indicating the brand name value incorporated in the piratical creativity.

A couple of complexities need to be unravelled here. One is that the actions of the Pirate Bay in particular have been represented as nonmalevolent. Essentially they would then be a form of class antagonism against profit-skimming oligopolists.

Conclusion

In this article we have looked at the creative sector/class. This notion has been very much put on the map by the recent writings of Richard Florida. It thus resurrects concepts of classes and sectors in society which have been somewhat dormant in economic and social thinking for a while. The notion of a creative class has been seen to be used in some cases as a designation for a group of functionally similar individuals but has also been used to represent ideologically unified agents. This comes to the fore in Brooks' critique of 'Bobo' society and also when we come to look at the issue of malevolent creativity. The most distinctive feature of the creative class literature is that it seems to minimize the importance of

conflict and exploitation. These have been the hallmark of the original uses of the concept of class in social analysis. It remains an open question whether branding those who engage in creative activity as a class contributes anything useful to the understanding of relevant phenomena. Inevitably, debate must also rage as to who is to be included in the definition of a creative class which, under Florida's broadest definition has controversially expanded to include psychiatrists amongst others.

Creative Trajectories

L M Cohen, Oregon State University, Corvallis, OR, USA

Glossary

Continuum of adaptive creative behaviors A continuum of seven levels that explains the connection between creativity in childhood and in the eminent.

Domain A body of organized knowledge, skills, and traits underlying a discipline, requiring specific preparation to reach high levels.

Expertise High levels of skills and knowledge developed through training and practice over long periods.

Networks of enterprise Productive endeavors in a variety of domains that connect and interact.

Pathway A course followed that has attributes of a social system having structures that constrain or enhance development.

Retrospective Working backwards from an endpoint; a research method that involves looking back at key change points, accomplishments, and connections in the past, typically used for studying creative trajectories.

Trajectory The general patterns of a life course associated with creative fruition as well as the specific itineraries taken by individuals.

Creative Trajectories

Although trajectories are an aspect of development, they describe the path or course taken over the life span and the end point of development (*final causes*: ends toward which development occurs that explain the organization and pattern of change), rather than focusing on specific changes over time, transitions, or stages on the journey (*formal causes*: underlying structures, rules, or forms that explain temporary stability of an organization). Individuals each have their own unique trajectory, although common patterns have been found across eminent creators. To understand creative trajectories requires studying a life retrospectively, considering both continuous and discontinuous processes and the unique person–environmental interactions that are mutually determining and reciprocal, according to Jane McLeod and Elbert Almazan. At the same time, understanding where early personality and intellectual patterns and educational opportunities may lead can help in considering the types of creative trajectories we wish to support in childhood.

Defining Trajectories

Trajectories are defined as a path of a moving object, a chosen or taken course, or, in Aaron Pallas' educational pathway terms, "well travelled sequences of transitions that are shaped by cultural and structural forces." Linda George noted that trajectories are long-term patterns of change and stability that are "unlikely to conform to simple monotonic linear, or even curvilinear forms." Pallas differentiated the terms trajectories and pathways, stating that educational trajectories are "an attribute of an individual whereas a pathway is an attribute of a social system." In this article trajectories are both the general patterns of a life course associated with creative fruition as well as the specific itineraries taken by individuals.

Socio-Economic Context for Creative Trajectories Development

According to Jean Piaget, although all young children are creative because they must invent the world, to reach higher creative levels typically requires supportive environments, with sufficient socioeconomic and familial possibilities. Pallas suggested that pathways can illuminate structures that support or inhibit this development through constraints, choices, or incentives. Opportunity structures, such as parents who value education or a social network that enhances job possibilities, as well as individual agency, the zeal to pursue a passion, can both lead to status attainment. He noted that while some young people by virtue of their socio-economic status have pathways that offer greater educational opportunities, which lead them toward higher educational levels and hence, greater creative possibilities, some individual trajectories may be influenced positively or negatively by the choices a person makes. However, Pallas stated that generally inequalities get passed along and forward, with the 'Matthew Effect' of keeping the rich, rich and the poor, poor. Thus, children who are fortunate enough to attend good schools, have supportive families, and positive role models are more likely to attain higher levels of creative development, in part because they believe they can. Victor Gecas stated that "self-efficacy concepts formed early become self-fulfilling prophecies" through early experiences, wherein individuals develop a sense of self-efficacy, motivation, and levels of aspiration.

Don Ambrose noted that individuals from low socio-economic classes, even though highly capable, often face insurmountable barriers in imagining or attaining their aspirations, while more affluent youngsters have greater opportunity. He called for schools and teachers to look for and support children of less privilege in order to optimize their development. However, there is no guarantee that bright children even from privileged backgrounds will attain their creative aspirations.

Confluences of Factors

To develop talents that reach high levels, Rena Subotnick and Paula Oleszewski-Kubilius described “intense involvement during childhood and adolescence,” as a forecaster of adult accomplishment and a hallmark of eminence. Ellen Winner, while acknowledging that there is limited room at the top of a field for greatness, suggested that eminent development may be better predicted by three dominant characteristics of gifted children: a rapid pace of development in a particular domain or domains, such as music or writing; enhanced ability for self-directed learning and intellectual independence; and the ‘the rage to master,’ an intense need to learn and understand that helps to sustain effort and practice needed to become great. Likewise, Mark Runco found that eminent creativity is not just based on innate talent, but on persistence, immersion in their domain, and family support.

Stephen Gorard, Gareth Rees, Ralph Fevre, and Trevor Welland described the set of confluences that bring individual choices together with opportunity determinants, such as time, place, age, gender, family background, and schooling. These choices are “affected by ‘horizons of action’, a view of what might be deemed appropriate for ‘someone like me’,” which can both enable and restrict. They also found in their retrospective life histories of over 1000 individuals that in addition to these opportunity determinants, the role of leisure interests and being an autodidact affected learning trajectories.

Age Curves: Typical Creative Trajectory Patterns

In his landmark study, Dean Keith Simonton statistically analyzed creative trajectories of a large number of creators in varied domains, finding predictable age curves for periods of high productivity and greatest contributions. These trajectories varied by discipline and onset time of the career, but most creators peaked in terms of greatest productivity and accomplishments about 20 years after starting their training (typically late 30s or early 40s). However, Simonton clarified that because the figures are averaged, “no creative person is forced to have his or her career follow the exact same course.” In a different study, he also noted that especially in some domains such as music, a swan song phenomenon is often observed, with late peaks. On the other hand, Laura Tahir and Howard Gruber suggested that such approaches oversimplify creative trajectories. They noted that “since every creative achievement is unique” and varies by task and individual over the lifespan, there is no average peak or age for best work. Rather, utilizing the evolving systems approach that considers knowledge, purpose, and affect in context across numerous cases, Tahir and Gruber stated that creative individuals have unique trajectories that differ from person to person, are marked by different peaks, different rates, and unique styles of collaboration. They suggested that creative work often continues into old age as a process of these productive evolving systems, with particular emphasis on collaboration and “the need to share the work with future generations” for immortality.

Educational Trajectories

Trajectories are typically studied retrospectively, looking at educational milestones and career transition points. Completing grade school, middle school, high school, and so forth are the milestones or transition points that lead toward creative career development. Studying trajectories of students with developmental disorders, infants, and other groups compared to those exhibiting typical development has been productive, especially when compared to chronological and mental age-matched control groups. One possibility might be to consider a similar analysis of trajectories of gifted and/or creative children. At issue is whether creative trajectories can be predicted from childhood. School-based transitions are probably less likely to predict eminent development than are personal qualities, domain capacities, interests, opportunities to work creatively, the willingness to put forth effort, and an amazing confluence of chance, historical, cultural, and other factors. Again, it is important to remember the uniqueness of each creator, a pre-tuned individual, in considering creative trajectories, the two major ones considered next.

Two Major Creative Trajectories: Poles on a Continuum

In the literature, creative lives are shown to follow two major trajectories, which can be considered as unfolding at opposite ends of a continuum. On one end are linear paths which involve the acquisition of expertise; on the opposite pole are networks of enterprises, varied domain involvements woven together. In my own work, I have shown that both acquisition of expertise in a field and development of networks of interest or enterprise outside one’s area of specialization appear to be essential requirements for high levels of creative accomplishment. These two poles are attractions that interact differently within the person and set in motion pulls on the creator. It would be problematic for a symphony composer with a more linear trajectory to not have an abundant array of interests and material to weave into the musical compositions. At the same time, in order to know what the problems and contradictions are at the periphery of a domain, the renaissance person must cultivate ample expertise in one or more areas. The two major poles on the continuum are described next.

Linear Trajectory

The linear trajectory is best described by Jonathan Baer, Benjamin Bloom, Sidney Pressey and the rich work on academic acceleration, such as studies by Mirica Gross, Karen Rogers, and Julian Stanley. Developmental psychologist David Feldman stated that great creativity can occur only when the individual has uniquely mastered a specific domain. For him, the creation of something new and unique in a field – the hallmark of creativity – occurs when a person has mastered that domain in such a distinctive way that he or she can make an original contribution to it. Such proficiency, according to K. Anders Ericsson and Andreas Lehman, necessitates an enduring commitment for accomplished performance. Robert Weisberg found it requires persistent practice from a young age designed

by coaches and teachers who prepare the young person with the objective of increasing the current level of achievement. He noted that to make mature contributions to a field typically entails at least ten years of vigorous learning of what is already known in a domain for competence and proficiency, requiring hours of focused, intense practice during those years to become an expert. In 2008, Malcolm Gladwell called this the “10,000 hour rule,” the time needed for extraordinary mastery.

A linear trajectory on the expertise-acquisition end of the continuum is typical of those persons who make contributions in mathematics, sports, chess-playing, musical performance, and more rarely, the fine arts. The young person becomes very accomplished at something, demonstrating extraordinary talent in a given field and occasionally mastering that domain to a level of adult expertise when quite young. Child prodigy studies have elucidated and provided insight into this type of trajectory (i.e., David Feldman, Martha Morelock).

Network Trajectory

Howard Gruber and colleagues offer a network view of creativity, the opposite end of the continuum. In his studies of Piaget and Darwin using his evolving systems approach, Gruber stated that creativity is the result of sustained work over long periods through the interactions of the systems of knowledge, affect and purpose in a network of enterprises (areas of productive endeavor and interest that relate to and influence each other).

It is the networks developed among and between these undertakings and supported through feelings and purpose that underpin the construction of originality and sustain the effort needed to bring processes or products to actualization in one-of-a-kind, pre-tuned individuals. Such network trajectories are consistent with individuals who may revolutionize a field or create new ones, in persons sometimes called geniuses or renaissance persons by the gate keepers in their field (although this does not always happen during the creator’s lifetime). Rather than following a single linear course, these network creators become productive and engrossed in several quite distinct areas of endeavor.

From a young age, Charles Darwin and Piaget both had multiple areas of involvement in which they did productive work. For example, Darwin was involved in such varied topics as coral reefs, animal and human emotions, earthworms, and geology, as well as theory building. Piaget studied certain mollusks and sedums and the notion of structure in a variety of disciplines such as mathematics and philosophy, as well as infant and child learning. Both men are examples of renaissance people who not only revolutionized their fields, but also the world in which we live. A question arises, however, as to whether such network creators spent intense, long years acquiring expertise in one domain, acquired expertise across several domains simultaneously, or developed the knowledge and skills needed for mature creative work somewhat differently.

Between the Poles

Between these two poles are creators who must assimilate knowledge and skills broadly in order to perceive the

characteristic properties and very essence of their domains of effort – individuals who make major contributions in the social sciences, philosophy, theoretical physics, writing, and other complex fields that are not set up and learned in a hierarchical or linear manner.

The poles are not completely exclusive. In fact, according to Robert and Michelle Root-Bernstein, cross-disciplinary approaches are important in the development of superior levels of creativity in any field. For example, in another study, Robert Root-Bernstein found that creative musicians often are polymaths who think across the disciplines, particularly mathematics and music, even though expertise in music is typically considered a more linear trajectory. Similarly, Simonton found that opera composers were more renowned if they employed versatility or cross training, composing in diverse modalities, such as Mozart, Debussy, and Tchaikovsky, in contrast to those who exhibited complex more focused expertise and only composed opera, such as Rossini or Puccini. The field of opera composing, he noted, involves integrating music with libretto, acting, costumes, and stage design, already requiring interdisciplinary thinking.

At the same time, network-type creators must be deeply knowledgeable about their domains. They must master one or more at the level of expertise required to know what is missing or what the problems are in order to do creative work. So linear creators benefit from cross training and network creators must develop expertise. In fact, Robert Sternberg suggested that just in the domain of creative leadership there may be as many as eight types of ‘propulsions’, which are similar in some ways to trajectories, in that individuals make decisions and orient activities in relation to their field, effecting changes in that field. But how these trajectories develop from infancy through eminence is little understood.

Development of Creative Trajectories

To understand how creative trajectories develop, creativity in early childhood as well as creativity across the lifespan needs to be considered. One perspective is based on ‘mini-c’, another on a continuum of adaptive, creative behaviors.

Mini-c, Pro-c, Little-c, Big-C Creativity

James Kaufman and Ronald Beghetto propose that all creativity begins at the ‘mini-c’ level, novel and personally meaningful creativity that is part of the learning process in interpreting events, actions, or experiences in all individuals. They noted that little has been done to recognize the importance of these early learning aspects or to consider the connection to Pro-c, the expertise-acquisition aspect and how individuals move from this level to ‘little-c’ creativity, wherein an individual has developed knowledge in a domain and may make a beautiful table, write a short story, or choreograph a school dance number. To go from little-c to ‘Big-C’ creativity depends on the subjective views of individuals functioning as leaders in the field, the gatekeepers of a domain who judge the product as a breakthrough or extraordinary and allow the creation to change the domain.

Continuum of Adaptive Creative Behaviors

From a different perspective, in *A Continuum of Adaptive Creative Behaviors*, I suggested that development of creativity spans seven discontinuous levels from earliest childhood through mature adulthood:

- Level 1: Universal Creativity (in all people from infancy; also when learning something totally new)
- Level 2: Rare Compared to Peers (the child or adult creates unusual perspectives, actions, products, questions)
- Level 3: Developing Talents (expertise acquisition of knowledge and skills)
- Level 4: Developing Heuristics (expertise acquisition of strategies and ways of doing things)
- Level 5: Producing Information (shift from adapting to a field to beginning to add information to it)
- Level 6: Creating by Extending a Field (linear trajectory)
- Level 7: Transforming or Revolutionizing a Field (network trajectory)

These distinctions are based on six variables: *adaptation* (initially the individual adapts to the world. Between Levels 4 and 5, the world begins to adapt to the individual); *purpose* (shifting from mastery, through extension, to transformation); *novelty* (new to the individual, then rare compared to age peers, finally new to the world); *value* (initially to the self, then others, then world); *speed* (rapid in early levels, very protracted at later levels); and *mental structures* (incomplete though transformational). It is in Levels 3 (Demonstrating Talents) and 4 (Developing Heuristics) that the individual works on acquiring domain mastery, probably more simultaneously. The two highest levels that typify highly creative adults, Level 6, Creating by Extending a Field and Level 7, Creating by Revolutionizing a Field, are themselves a continuum, representing the two polar trajectories just described. Level 6 is typical of creators who are more linear and acquire expertise in their own field, those who extend the domains in which they work. They often, however, connect interests and content outside their own domains to make creative contributions. Level 7, transformational or revolutionary creativity, is attained most often by creators who develop networks of enterprise and make connections among their own specialty and others. In addition, they must establish extensive proficiency in at least one domain.

Importance of Early Interests

My colleague, Judy Gelbrich, and I also pointed out that interests which begin in very early childhood are the seeds of creative development. Born of disequilibrium among and between systems of knowledge, affect and other internal systems in interaction with the external world, the child cultivates passionate interest quests around 'centers of action'. Patterns in these quests become apparent quite early with interests clustered around six themes. Similarly, Jonathan Feinstein associated interests from childhood and young adulthood with creative development, wherein passions and interests direct the creator's attention. In the developmental phase, individuals connect to and conceptualize these interests; in the exploration phase, they engage with receptiveness in these involvements and develop unique structures in interest areas;

and finally, they execute projects embedded in pursuits that lead to creative work and significant contributions. It is the interest passions, the 'fire in the crucible' that lead the child to vigorously pursue an area and to work toward mastery, perhaps connecting this passion to other areas of interest and to the potential for creative trajectory development.

Conclusion

It is not possible to predict which child will make major contributions in either the linear or network type of trajectory. As Jane McLeod and Elbert Almazan noted, the focus is on person-environmental interactions that are mutually determining and reciprocal, with discontinuities as the rule, not the exception. They suggested that focus should be on the "relationship between structure and agency and the nature of psychological and social structures, how they are perceived, and how they influence behavioral choices." At the same time, there are proclivities and characteristics in children that are more likely to suggest potential for high levels of creativity, given opportunity, chance factors, personal drive, and the right mix of people, history, and culture. But to recognize that there are different pathways, linear, network, and in-between, implies that tuning into the passions of childhood and providing supportive environments in and out of school, rather than channeling direction too soon, may yield greater possibilities for creativity at the highest levels.

Glossary

Art bias The unjustified assumption that creativity is only manifested in art.

Complex Often used in clinical psychology and psychiatry to describe systems of interrelated characteristics that covary and are related to a particular psychopathology.

Disappearance of the problem Someone becomes so interested in solving a problem that it is transformed into an

enjoyable challenge and the person no longer views it as a problem.

Parsimony A guiding principle of modern science that emphasizes simplicity of explanation. All other things being equal, the simple explanation is best.

Syndrome A set of symptoms or indicators, often used to define or predict disorders or behavioral tendencies.

Introduction

Creativity has only been recognized as a fitting topic of scientific study for 30 or perhaps 40 years. There were several systematic investigations well before that – including Catherine Patrick's series of studies with various professions in the 1930s – but archival analyses of publications and citations on the topic of creativity show that empirical work was sparse until the 1960s. There were several reasons for this. One is that creativity was (and often still is) equated with art. That in turn ties it to aesthetics and values and topics that are so closely connected with subjective processes that most scientists assume they best belong in the nonempirical domain. The assumption that creativity is always tied to art is still quite common and has been called an *art bias*. It is especially problematic in education because it may lead teachers to assume that only students with clear artistic talents are creative.

A second reason creativity was excluded from the behavioral sciences for so long is that it has varied etiology and possible expression. It is influenced by personality, cognitive and extra-cognitive processes, settings and culture, development, mood, attitude, affect, and even *Zeitgeist*. It is also expressed in a variety of ways, including artistically, but also technologically and in innovation, entrepreneurship, invention, and diverse kinds of problem solving. No wonder creativity has been defined, almost from day 1, as a 'complex' or 'syndrome.'

This article reviews theories which explicitly define creativity as a complex. It also examines their assumptions and contrasts the definition of a complex with the opposite view, namely the *parsimonious theory of creativity*. Coverage is probably broader than may be suggested by the label *creativity complex*. That is because the creativity complex often goes by other names. *Creativity syndrome* was used in 1965 by Donald MacKinnon, a key figure in the early research done at the *Institute of Personality Assessment and Research* (see IPAR in volume 1 of the *Encyclopedia of Creativity*), and by Michael Mumford and Sigrid Gusgafson in their influential article from 1988 in the *Psychological Bulletin*. They also referred to *multivariate perspectives* on creativity. Then there is the idea of a *multilevel theory* of creativity. The last of these is an attempt to emphasize the fact that creativity is often influenced by the individual, the immediate setting, and

the general culture (be it organizational, geographical, or both). As we shall see when the advantages and disadvantages of the definition of creativity as complex are reviewed, the best label for the complex may be *multivariate*. That covers all of the different theories that explicitly describe the variety of influences and expressions of creativity, and it avoids unwanted connotations. More will be said about this below, after the facets of the complex are covered.

Defining Creativity

The research on creativity certainly does point to a large number of influences and correlates, some personal (e.g., affect, cognition, personality), some environmental (e.g., setting and resources), and some cultural (e.g., values) and interpersonal (e.g., encouragement and support). The idea of a complex also allows diversity of expression, which is quite important given the differences among domains of creative endeavor and among kinds and levels of creative performance. Creativity can be expressed by a child, using his or her imagination, for example, but it can also be used by world-class experts when solving highly technical or far-reaching social problems. In slightly different terms, creative talent is often apparent in the lives of eminent persons, but 'everyday creativity' also allows each of us to deal with the hassles and surprises of our existence. The point is that creativity is complex in two very different ways, one representing its etiology and the other its expression.

As a matter of fact the complexity of creativity is apparent even if the focus is on one particular creative event or product and not only when its diverse expressions are examined. That is because all creative things, be they inventions, innovations, works of art, scientific breakthroughs, or original solutions to everyday problems, share more than one attribute. There is one primary attribute, which is originality. All creative things are novel, unusual, unique, or in some fashion original. Originality is necessary but not sufficient for creativity. It is not sufficient for creativity because original things are sometimes not creative. Something may be original but useless or ineffective. This is where the third kind of complexity comes in (to go along with its complex etiology and expression): creative

things are, at a minimum, both original and effective. Further, each of these two attributes can be defined in more than one fashion! An original thing might be entirely unique, for example, or it might be merely highly unusual. Even more to the point, the effectiveness of creative things may be determined in numerous ways. In the case of creative solutions to problems, effectiveness is supported by the fact that the problem is solved. But not all creativity involves problem solving. In the arts the effectiveness of creative things is typically aesthetic rather than purely functional. Along the same lines, creative art may be produced to express oneself rather than to solve a problem. Admittedly artists sometimes have problems finding the best ways to express themselves. Conversely, someone may be so interested in solving a problem that it is transformed into an enjoyable challenge and the person no longer views it as a problem. This has been called *the disappearance of the problem*.

Some definitions of creativity include a social component. The assumption is that things or people are only creative if an audience attributes creativity to them. Although many domains do in fact rely on audiences and social judgment, there are serious problems with any definition that requires social attributions. This would, for example, exclude many everyday creative efforts, and these may constitute the largest of domain of creative efforts by far. A social requirement would also exclude children's creativity, at least if it assumes that creative things must be original when compared to social norms and standards. Children may be original, in play or imagination, but much of what they do is original only on a personal level and not if compared to what others have done.

The real problem with a social requirement in the definition of creativity is that it confuses creation with reaction. To include attributions would be a bit like saying that the talent of a public speaker depends on the hearing of his or her audience. For the scientific study of creativity, it is best to keep creation separate from reception and from possible attributions. For this reason the list of influences given below to exemplify creativity as a complex focuses on individual factors, such as cognitive talent or personality. It excludes social and cultural influences. These may actually influence creative efforts, especially if you consider that creative potentials are probably not developed unless they are valued by the culture and society in which they are expressed. Still, the focus here is on personal and intrapersonal influences and excludes social influences. In addition to being consistent with the notion of creativity as creation and not superfluous social reaction, this insures that the conclusions about the creativity complex offered below are, if anything, conservative. Creativity would be even more complex if social attributions were included. Quite a few social and cultural influences, including those experienced in the home, school, or work setting, are detailed elsewhere in this same volume.

Diverse Influences on and Expressions of Creativity

The view that creativity is a syndrome or complex is typically justified by the fact that there are diverse influences on its development and diverse forms of expression. Examples of these diverse influence and diverse forms of expression are

easy to find. Several different kinds of cognitive capacity and skill have, for example, been associated with creative thinking. Creative thinking may involve imagination and insightfulness, for example, as well as a tendency towards divergent thought. Divergent thinking in turn is usually operationalized in terms of several kinds of ideation, including fluency and originality. Creativity also seems to benefit from metacognitive processes, such as an intentional attempt to shift one's perspective or to put a problem aside to allow incubation.

Diverse cognitive influences on creative thought are also apparent in stage theories of the creative process. Wallas' four-stage model is the best known of these, though presented long ago (1926). It includes preparation, incubation, illumination, and verification. More recent renditions include an implementation stage, which makes sense if the emphasis is on innovation or practical applications of creative thinking. A two-tiered model of the creative process includes many of the same stages but views preparation as a kind of problem finding. It divides this into problem identification and problem definition, which of course adds complexity. There is also an ideation stage, which is divided into those same tendencies mentioned above (fluency, originality, flexibility), and evaluation, which may be divided into *valuation* and *evaluation* (the former being appreciative, the latter critical) and into inter- and intrapersonal judgments. The two-tier process model also recognizes the potential impact of knowledge and motivation, and as you might expect divides the former into procedural and declarative (or conceptual) knowledge, and the latter into intrinsic and extrinsic motives.

Various *cognitive styles* have been associated with creative thinking. There is, for example, empirical data on the role of assimilator innovator, adaptors, and explorer styles. Even the long-standing style theory that contrasts deliberate with impulsive tendencies has been associated with creative thinking.

Complexity is also suggested by the fact that creative thinking differs with the domain or subject matter. Creative thought can draw on verbal skills, but it may also rely on imagery, preverbal processes, and 'preinventive forms.' Because many of these differences in the mode of thought can be understood as domain differences, more will be said about them below, in the section on diverse expressions of creativity. At this point it should be clear that, even within the cognitive category of influences, there are numerous possibilities. The concept of a complex makes sense.

The same is true when considering the influence of personality on creative efforts. The most important personality traits for creativity seem to be openness, autonomy, wide interests, flexibility, and intrinsic motivation. The last of these suggests that there are motivational and therefore affective bases to creativity. Plenty of research indicates that mood influences the thinking tendencies that support or inhibit the likelihood of finding original insights.

Attitudes also play a role in creative efforts. Again, there are a number of different possibilities, including openness to divergence – which fits well with theories of divergent thinking – playfulness, and tolerance. There are also attitudes which most likely inhibit creative behavior, including tendencies towards *satisficing* or premature closure. Note here the idea that there are supports for creativity as well as probable

inhibitors. This same dichotomy applies to virtually all influences, be they cognitive, personality, attitudinal, or whatever. It may not literally double the complexity of creativity, but it certainly does dramatically increase the range of influences.

The diverse expressions of creativity, which also help explain why it is viewed as a complex, are very easy to summarize. Much of the early research on creativity – including that mentioned above and conducted at the *Institute for Personality Assessment and Research* – involved writers, architects, and other professional groups, and data supported the idea that creativity differ from group to group (and domain to domain). Howard Gardner's theory may be the most formalized delineation of domains. It includes verbal, mathematical, spatial, bodily-kinesthetic, intrapersonal, interpersonal, musical, and naturalistic domains. Gardner argued convincingly that these differ from one another in their biological, developmental, and cognitive bases. His is not a theory just of creativity but subsequent research has largely supported the same set of domains.

Subdomains are also described in the creativity literature, and they too imply that creative talents can be expressed in diverse ways. Even in an area such as language there are differences between poetry, drama, novels, lyrics, and oral communication, just to name a sample of what might be called subdomains. The various sciences also differ, especially if the hard sciences are contrasted with the social sciences. Then there are the different possible expressions of creativity at different ages, as implied by what was said above about children's creativity. Although there is a bit of discussion in the creativity research about the possibility that there is a commonality among domains and all possible expressions, that would not really eliminate the obvious fact that creativity takes many forms. At most, if a commonality is uncovered, it would mean that there are both similarities and differences among domains and the possible expressions of creativity. Thus, given its etiology (e.g., the influences mentioned above) and its varied expression, it is easy to see why it is so common to view creativity as a complex.

Parsimonious Creativity

The definition of creativity as a complex is consistent with much of the research on the topic and has a number of advantages. It applies very broadly, for example, as is apparent in the long list of influences and diverse domains of expression mentioned just above. Yet there are also disadvantages. One is suggested by the connection of 'complex' and 'syndrome' to psychopathology. These labels are in some ways applicable to creativity—they both imply that there is a set or system of relevant symptoms or indicators – but those labels frequently connote psychopathology. Given misconceptions of the association of creativity with psychopathology (e.g., creator as 'mad genius' or necessarily bipolar or suicidal), this is a potential disadvantage. That is why earlier I suggested that it may be best to view creativity as *multivariate* in its etiology and expression. That label also allows for a set of indicators but does not have the same connotations as *complex* or *syndrome*.

A second concern with the creativity complex is more significant. This reflects what is inherent in any complex: it is complicated. More to the point, it is not *parsimonious*.

Parsimony is an important part of all sciences. It requires simplicity of explanation. All other things being equal, the simple explanation is best. Is a parsimonious definition of creativity possible? To define creativity in this fashion, there must be something common to all creativity.

It may be difficult to see what is common to all creativity, given all of the various influences and diverse expressions (e.g., domains and differences at different ages). Perhaps a commonality can be found if one step is taken at a time, to narrow the field and remove each unnecessary part of the complex in a systematic fashion.

The first step towards parsimony is dictated by the scientific concern for *causality*. Without a doubt, at the heart of all scientific theories is an interest in uncovering actual explanations for events and actions. Good science does not merely describe; it also explains, and a good explanation must identify specific causal factors. This is why experimental research is so highly respected: it eliminates confounding factors and nuisance variables so causes can be unambiguously tied to effects. A parsimonious theory of creativity should focus on explanations rather than descriptions. It must identify causes.

Thus the first step towards simplifying the complex involves eliminating effects of creativity. These may be interesting, and socially or personally useful, but they are not causes and not really explanatory. A great deal of the creativity literature describes effects, and all of those findings can be ignored for a parsimonious theory. Effects are on the wrong side of the causal equation and thus do not advance the parsimonious theory of creativity. Certainly causes can sometimes be inferred from effects, but it may not be necessary to resort to such inferences.

As a matter of fact, many of things that make creativity seem complex are effects of creative behavior. As such they make themselves known only after creativity has occurred! Recall here that social definitions of creativity were dismissed above because they are reactive and not a part of the actual creation. Other effects and results include the products which are so often studied in creativity studies. They too can be put aside since they do not offer direct information about causality. Creative products are original and useful, and they may be highly desirable, but they do not explain creativity. They cannot be used to control the creative process, and any theory based on them is post hoc and much more descriptive than explanatory. It will also lack generality, given that many creative experiences do not lead to a lasting product.

A second but more difficult step towards parsimony involves putting aside all 'mere influences' on creativity. Influences can be dismissed because they offer no guarantees. They are not really determinants. Influences may have some impact, but that is not the same thing as causality. Mere influences are much weaker than actual causes, much less reliable, and insufficient as scientific explanations.

Think back on the influences reviewed above, when the theory of a creativity complex was being outlined. Consider each of these individually and ask, does all creativity depend on this influence? Does all creativity depend on, say, intrinsic motivation? It does not; there are many cases where extrinsic incentives are key. Is all creativity a result of a particular mood, or even dependent on a particular cognitive process? Far from it: for some tasks, one mood seems to be best, while for others,

another mood is conducive to creativity. Or it may be that the most supportive mood varies from stage to stage of the creative process. The same thing can be said about cognitive processes. In fact it can be said about all potential influences. They do not apply all of the time.

Creativity can be defined parsimoniously if it includes only what is always vital and necessary. All else is extraneous. This allows us to exclude even more than products, effects, and results of the creative process. The literature on influences probably constitutes the largest portion of creativity studies. And like the research on products, it is useful. It may suggest how to make creative work more likely, for some people, some tasks, some of the time. But a parsimonious definition of creativity includes only what is necessary, not just what is sometimes influential.

There really is very little that is vital and necessary for all creativity. In fact, the only things that are universal and necessary were mentioned above. They are (a) originality and (b) effectiveness. Granted, there is variation in the wording. Sometimes originality is labeled novelty, for example, and sometimes effectiveness is labeled adaptive, fit, or appropriateness. Whatever the label, originality and effectiveness are vital for all creativity. This is not all that constraining, either. Originality and effectiveness apply to all domains and all categories of research. Thus (a) creative products are original and useful; (b) creative persons have the capacity to be original and find or produce useful things; (c) creative places are those that support the production of original and useful things; and (d) the creative process is involved when a person produces something that is original and useful.

The objective of a parsimonious theory is to keep things as simple as possible. That does not necessarily mean that everything is removed and excluded, one by one, until only one causal factor remains. Obviously the epitome of parsimony would be a theory which points to one causal factor that explains everything. But parsimony can be taken too far, in which case it loses its value. If too much is removed, just for the sake of simplicity, accuracy and understanding are lost and parsimony has done science a disservice. Even though the method used here, which excluded influences and factors which do not apply to all creativity, only reduced the list to two requirements, originality and effectiveness, that may be the best we can do. It may not be possible to distill theories any further, at least if we wish to accurately understand true creativity. But a two-factor theory of creativity is much more parsimonious than those relying on the idea of a creativity complex.

Conclusions

The idea of a creativity complex is in some ways useful. It suggests that original and effective behavior in diverse domains can all be considered under the general umbrella, 'creativity.' It offers breadth.

There are, however, several problems with the idea of complex. One is just semantic – the connotations of the labels complex or syndrome. The other is much more significant. It implies that studies of creativity are still not entirely scientific. After all, the sciences focus on causality and value parsimony, and the creativity complex is nearly the opposite of parsimony and includes many things that offer little or no causal information.

The scientific requirement of parsimony is usually taken to mean that, when there are various explanations for some phenomenon, the simplest one is best. That in turn supports the parsimonious theory of creativity that only includes originality and effectiveness. Parsimony requires that everything that which is not vital is excluded. This really just means that the creativity complex can be simplified if the focus is on that which is involved in all creativity, not just some creative things.

The idea of a complex is untenable according to the primary goals of science, which are prediction and control. These two things, prediction and control, were used by B. F. Skinner as standards of rigorous science. Think of the benefits if creativity could be accurately predicted and controlled. Those make the parsimonious approach to creativity all that more attractive.

Glossary

Analogy Involves seeing how something new (target) is like something old (source).

Metaphor An 'as if' comparison, thinking about *X* as if it were *Y*.

Psychology of science The scientific study of both implicit and explicit scientific thought and behavior.

Scientific creativity Any thought or behavior in science that is both novel and useful; with creative thought or behavior in science being manifested throughout the scientific process, from theory construction and hypothesis formation, research and study design, to publication and communication of results.

Creativity in Science

When many people are asked about creative activities, they inevitably conjure up artistic creations: poems, novels, photographs, plays, sculptures, songs, etc. And if asked if they are creative they often say no precisely because they are not involved in such activities. Yet creativity is hardly the sole province of art. Creative thought and behavior happen in any and all domains of life, from cooking, building, and surviving to science. Indeed, science ranks up there with art as an occupation that would not exist if it were not for creative ideas and creative solutions to problems.

Although science requires as much creativity as art, its form and expression are somewhat different. Whereas artistic creations may involve often personal visions and emotional reactions to one's world, scientific creations involve ways to test our ideas about how the world works – and the world is not just the physical world, but rather the biological and social worlds as well. Creative insight is a must in science.

How is creativity in science manifested? The simple answer is nearly every aspect of science – from grand theory building to minute technical solutions to lab problems – involves creative thought. After all, as many other writers in this *Encyclopedia* have pointed out, creative thought and behavior must be both novel/original and useful/adaptive. Therefore, 'scientific creativity' is simply any thought or behavior in science that is both novel and useful; with creative thought or behavior in science being manifested throughout the scientific process, from theory construction and hypothesis formation, research and study design, to publication and communication of results. New and important discoveries in science come about often because of creative ideas and hunches of the scientists behind them. Of the thousands of new scientific articles being published world-wide each month, the vast majority of them are published precisely because they report some original finding, technique, or discovery. Creativity in science is less and less manifested in the 'lone genius' and more and more in the scientific team or laboratory. Creativity in science occurs both at the individual and the group level. Either way, it is clear that science and creativity go hand in hand. What does the scientific literature have to say about the nature of scientific creativity?

The Science of Scientific Creativity

There is a newly established discipline that is well-situated to explore and uncover the nature of scientific creativity and that discipline is the psychology of science. The 'psychology of science' is the scientific study of both implicit and explicit scientific thought and behavior. As Feist argued in *The Psychology of Science and the Origins of the Scientific Mind*, psychology is the only study of science that examines scientific thought and behavior from an empirical and even experimental perspective. Hence, the psychology of science is well-situated to uncover the nature of scientific creativity. In 2006, the first organized society in the psychology of science formed, the 'International Society for the Psychology of Science and Technology' (ISPST). Psychologists of science systematically study scientific interest, thought and behavior, often with a particular interest in genius, talent, and creative thought in science. The psychology of science has empirically focused on at least four major elements of creativity in science: neural complexity, development of scientific talent and achievement, personality traits of highly creative scientists, and creative cognition in science.

Neural Complexity

One of the more exciting recent perspectives on creativity is the neuroscientific perspective. Each year, more and more is being uncovered about the neural foundations of creative thought, including scientific creativity. One general conclusion from this research is the brains of creative people are often marked by more complex and more highly interconnected neural circuits than those of less creative people. That is, highly creative people appear to have greater neural connectivity between all major associative regions of the brain. Such a finding would be consistent with one of their most consistent and robust abilities in the creativity literature, namely, that creative people generate many more ideas, and the ideas they generate are looser and more remote in their associations. They are more cognitively fluent. This may be so because of a brain that simply has more connections, making rich associations more likely. Idea generation is as much about making connections as anything. Indeed, the frontal lobes themselves may well be especially important in this overall greater neural connectivity

given the frontal lobes do more to connect various regions of the brain than any other lobe.

The neurological condition known as synesthesia appears to be related to creative associations. Synesthesia occurs when two or more of a person's sensory modalities (taste, smell, touch, seeing, and hearing) get mixed. For example, a synesthete may experience colors when perceiving numbers or smell words. More than a few of our most creative scientists, inventors have had synesthesia, including Richard Feynman, Daniel Tammet, and Nikola Tesla. One compelling theory for synesthesia put forth by Ramachandran and Hubbard is that it results from a cross-wiring or cross-activation of sensory neurons in various parts of the brain such that, for instance, brain regions involved in color perception get cross-activated with sensations of numbers. Some extraordinary mathematical ability results from synesthetic perception of number, as most clearly seen in the savant Daniel Tammet. Creativity and synesthesia share neural complexity in common.

Development of Scientific Talent

A recent documentary film, 'Whiz Kids,' documents the coming of age drama and scientific talent and drive of three high school Intel Science Talent Search applicants. The film portrays the intelligence, drive, emotion, and personality of students as they navigate the world of world-class – and competitive – science.

Indeed, another critical question examined by psychologists of science is a developmental question: Where does scientific creativity come from? Like all creative achievement, scientific talent has a life-span trajectory. Certain children, based on a combination of talent and training, are more likely to go into science than others, and even particular kinds of science than other kinds. But going from childhood interest to adult scientific achievement is a long and complex process. Many obstacles and life circumstance intervene and many potential scientists change career paths. Moreover, once a scientist, there is a wide range of creative ability and the focus in this chapter is on creative talent and achievement in science. What, then, are the psychological factors behind creative talent and achievement in science and how do these factors change across the lifespan? Taken as a whole, the literature on these questions does provide some pieces to the puzzle of scientific productivity.

Scientific creativity and talent across the lifespan

Historically, the first scientific work on the development of scientific talent and creativity develops was conducted by Francis Galton in the 1870s. Most relevant to the current chapter, Galton's book *English Men of Science* in 1874 pioneered work on birth-order and scientists and found that scientists were more likely to be first-born children than nonscientists.

The first systematic and longitudinal research program that shed light on the development of scientific talent was conducted by Lewis Terman, beginning in the 1920s. His study included children if they had tested IQs of 140 or higher. More than 1500 children qualified and participated, with the first sample being tested in 1921 (when most of the children were about ten years old). They were assessed once or twice a decade for the next 60 years. By following the cohorts over their entire adult lives, Terman and his colleagues were able to answer the

important question of what happens to our brightest children. Do they go on to very productive and creative careers? The answer is 'yes' to productive, but 'not really' to creative. Although the sample as a whole achieved higher than normal levels of education and career success, if one uses standard creativity criteria (impact, productivity, and honors and awards), the Terman group in general was surprisingly uncreative over the course of their careers. No major writers, artists, or scientists emerged from this 'genius' level IQ group. Indeed, two future scientists who were tested by Terman – William Shockley and Luis Alvarez – but did 'not make the cut' went on to outperform any of the Terman subjects by receiving Nobel prizes in physics.

The next major longitudinal investigation that focused even more closely on scientific talent development was begun by Julian Stanley at Johns Hopkins in the 1970s and has continued under the leadership of Stanley's students Camilla Benbow and David Lubinski, now at Vanderbilt University. The project is known as the Study of Mathematically Precocious Youth (SMPY) and it targets children under the age of 13 who show precocious signs of mathematical talent. Results from these studies have reported that precocious ability does predict achievement in high school and in college. More recently, Benbow and colleagues reported that approximately 90% of the SMPY sample go on to earn bachelor's degrees, slightly less than 40% get master's degrees, and about 25% receive doctorates. These figures are well above the base-rates for such degrees in the general population (with 23%, 7%, and 1% being the national figures, respectively). Similarly, Lubinski and colleagues reported in 2006 that talent-search SMYP participants who scored 700 or above on either one of the SAT subscales (quantitative or verbal) before age 13 went on to have very successful careers 20 years later, especially in math, science, or engineering. For example, nearly half of them were postsecondary teachers, scientists, or engineers. More specifically, about 15% of the talent-search females and about 9% of the talent-search males were in tenure track or tenured positions by age 33 – rates much higher than the general population.

Most directly relevant to scientific creativity and talent, Rena Subotnik and her colleagues were the first psychologists to systematically examine the longitudinal paths of scientifically talented young people. She focused on finalists and semifinalists for the country's most prestigious and elite science talent search competition, the so-called Westinghouse competition (now known as the Intel competition). It involves more than 1500 high school juniors and seniors every year, of which the top 300 are semifinalists and the top 40 are finalists. Subotnik followed up one cohort of semifinalists from 1983 and were able to collect data on approximately 100 of the 300 finalists/semifinalists. Eight years after being semi-finalists and finalists, 49 of the 60 males (82%) but only 25 of the 38 females (66%) were still in science or science related fields (including graduate school). Moreover, as Joseph Berger has reported on the entire sample of Westinghouse finalists, they do garner awards and recognition for their continued excellence for scholastic and career achievements. For instance, in the entire population of finalists up through 1994 five have gone on to earn Nobel prizes, 28 have become members of the National Academy of Sciences, and at least eight MacArthur Fellows have been awarded.

A few researchers have addressed the question of who is likely to make significant contributions to science and if so did they show early signs of their talent. Feist, for instance, examined the development of scientific interest in Westinghouse finalists and members of the NAS. For Westinghouse finalists, both men and women knew science was for them at an equally young age – by age 12. Members of the National Academy also developed an interest in science at a very early age, with 25% knowing they wanted to be a scientist by age 14, 50% knowing by age 18, and 75% knowing by age 20. In terms of first realizing they had talent for science, 25% of the NAS members realized their talent by age 13, 50% by age 16, and 75% by age 21. The range was ages 5–33. Finally, NAS members began doing science early, with 75% having participated in formal research by age 21, and no gender difference between men and women. Half of the NAS members had published a scientific article by age 23, and at least one member had published by age 16. Those who go on to have real talent in science as adults seem to realize at a young age that they want to become a scientist. Given that most college students change their major many times during their four years as an undergraduate, to have a group know by the end of high school or before that a particular career is right for them is quite remarkable. Early and clear insight into one's career calling is often an indicator that one knows where one's talents lies, and indeed such 'crystallizing experiences,' as Howard Gardner has called them, are frequently seen in adolescents who go on to be our most creative adults.

Age and scientific productivity

The oldest and most established question concerning the development of scientific productivity is of growth curves and publication rates, that is, how productivity (i.e., publication rates) changes with age. As Dean Keith Simonton has often reported in his reviews of the literature, the findings have converged on the conclusion that the relationship between age and productivity in science (and other professions) is curvilinear: scientific productivity increases steadily over the first 20 years of a scientist's career, plateaus, and then gradually declines. In other words, it forms an inverted-U.

Similarly, in a study of National Academy of Science (NAS) members Feist reported three unconditional growth curve models that were constructed to test Simonton's curvilinear model of age and productivity, namely a linear model, a quadratic model, and a cubic model. Each model provided a close fit to the data, suggesting that publication rates increase over time. Out of the three models, however, the curvilinear model provided a better fit than the linear model, and the cubic model a better fit than the curvilinear model. In other words, a model with two peaks (approximately 20 years into one's career and then again at the very end) was the best model of age and productivity.

Related to age and productivity there is the question of whether early recognition of talent and producing works early in life predicts later levels of productivity. The empirical consensus is that early levels of high productivity do regularly predict continued levels of high productivity across one's lifetime. Those who are prolific early in their careers tend to continue to be productive for the longest periods of time.

Lastly, there is also the question of whether the age at which one's talent for science is first expressed predicts lifetime

achievement in science. Regarding age of recognized talent, Feist predicted that in a sample of NAS members, age of talent should predict age of publishing and obtaining the Ph.D., which in turn should predict productivity and impact. Results showed that the four precocity variables were modestly positively correlated with age of first publication, which is an intermediate variable between precocity and achievement. In other words, the younger NAS members were when they and others recognized their scientific talent, when they wanted to be a scientist, and when they first conducted scientific research, the younger they were when they published their first paper. Age of first publication in turn predicted total publication rate over the lifetime, meaning the earlier one publishes the more productive one will be. This pattern of relationships – from precocity to age of first publication to lifetime productivity – implies an indirect connection between precocity and publication rate. The only precocity variable that predicted lifetime productivity was age that one first conducted formal research.

Creative Personality in Science

The development of scientific talent, achievement and productivity over the life course is one focus of psychologists of science who are interested in scientific creativity. Another focus is the unique personality characteristics of highly creative scientists.

One model of personality that explains the connection between personality traits and behavior, including scientific creativity, is the so-called functional model. The basic idea of this model is that traits function to lower behavioral thresholds. If a person has a particular trait, then corresponding behaviors are more likely (have lower thresholds) in given situations. A person with a friendly personality, for instance, is more likely to behave in a friendly and warm way than a person without such a trait. Applied to creative behavior, certain personality traits make creative thought and behavior more likely. What then are these personality traits, in particular as they relate to scientific creativity? A meta-analysis published in 1998 by Feist addressed the question of which traits make creativity and eminence in science more likely and what their magnitude of effect was (see Batey and Furnham for a recent qualitative review of the general creativity and personality literature). The traits can be arranged into three psychologically meaningful categories: cognitive, motivational, and social.

Cognitive traits

A consistent finding in the personality and creativity in science literature has been that creative and eminent scientists tend to be more open to experience and more flexible in thought than less creative and eminent scientists (see [Table 1](#)). Many of these findings stem from data on the flexibility (Fe) and tolerance (To) scales of the California Psychological Inventory. The Fe scale, for instance, taps into flexibility and adaptability of thought and behavior as well as the preference for change and novelty. The few studies that have reported either no effect or a negative effect of flexibility in scientific creativity have been with student samples. For instance, in 2003 Feist and Barron examined personality and creative achievement in a 44-year longitudinal study. More specifically, they found that personality variables (such as tolerance and psychological mindedness) explained up to 20% of the variance over and

Table 1 Personality traits that make scientific creativity more likely

Cognitive traits
Openness to experience
Tolerance
Flexibility
Motivational traits
Driven
Ambitious
Intrinsically motivated
Social traits
Dominance
Arrogance
Hostility
Introversion
Self-confidence

above potential and intellect. Specifically, two measures of personality – California Psychological Inventory scales of Tolerance (To) and Psychological Mindedness (Py) – resulted in the 20% increase in variance explained (20%) over and above potential and intellect. The more tolerant and psychologically minded the student was, the more likely he was to make creative achievements over his lifetime.

Motivational traits

The most eminent and creative scientists also tend to be more driven, ambitious, intrinsically motivated, and achievement oriented than their less eminent peers (see [Table 1](#)). In 1984 Busse and Mansfield, for example, studied the personality characteristics of 196 biologists, 201 chemists, and 171 physicists, and commitment to work (i.e., ‘need to concentrate intensively over long periods of time on one’s work’) was the strongest predictor of productivity (i.e., publication quantity) even when holding age and professional age constant. Similarly, Helmreich and colleagues studied a group of 196 academic psychologists and found that different components of achievement and drive had different relationships with objective measures of attainment (i.e., publications and citations). With a self-report measure, they assessed three different aspects of achievement: ‘mastery’ preferring challenging and difficult tasks; ‘work’ enjoying working hard; and ‘competitiveness’ liking interpersonal competition and bettering others. Helmreich and his colleagues found that mastery and work were positively related to both publication and citation totals, whereas competitiveness was positively related to publications but negatively related to citations. Being intrinsically motivated (mastery and work) appears to increase one’s productivity and positive evaluation by peers (citations), whereas wanting to be superior to peers leads to an increased productivity, and yet a lower positive evaluation by peers. The inference here is that being driven by the need for superiority may backfire in terms of having an impact on the field.

Social traits

In the highly competitive world of science, especially big science, where the most productive and influential continue to be rewarded with more and more of the resources, success is more likely for those who thrive in competitive environments, that is for the dominant, arrogant, hostile, and self-confident

(see [Table 1](#)). In a classic study in the 1950s, Van Zelst and Kerr collected personality self-descriptions on 514 technical and scientific personnel from a research foundation and a university. Holding age constant, they reported significant partial correlations between productivity and describing oneself as ‘argumentative,’ ‘assertive,’ and ‘self-confident.’ In one of the few studies to examine female scientists, Bachtold and Werner administered Cattell’s 16 Personality Factor to 146 women scientists and found that they were significantly different from women in general on nine of the 16 scales, including dominance (Factor E) and self-confidence (Factor O). Similarly, Feist in the 1990s reported a structural equation model of scientific eminence in which the path between observer-rated hostility and eminence was direct and the path between arrogant working style and eminence was indirect but significant.

The scientific elite also tend to be more aloof, asocial and introverted than their less creative peers. In a classic study from the 1950s concerning the creative person in science, Anne Roe found that creative scientists were more achievement oriented and less affiliative than less creative scientists. In another seminal study of the scientific personality, Bernice Eiduson found that scientists were independent, curious, sensitive, intelligent, emotionally invested in intellectual work, and relatively happy. Similarly, Jack Chambers reported that creative psychologists and chemists were markedly more dominant, ambitious, self-sufficient, and had more initiative compared to less creative peers. More recently, J. P. Rushton and his colleagues conducted factor analyses of the personality traits most strongly loading on the ‘research’ factor (in contrast to a ‘teaching’ factor) in two separate samples of academic psychologists. Among other results, they found that ‘independence’ tended to load on the research factor, whereas ‘extraversion’ tended to load on the teaching factor.

To summarize the distinguishing traits of creative scientists: they are generally more open and flexible, driven and ambitious, and although they tend to be relatively asocial, when they do interact with others, they tend to be somewhat prone to arrogance, self-confidence, and hostility.

Creative Cognition in Science

As Ryan Tweney once wrote: science, by its very nature, is a cognitive act. We could add that creativity, by its nature, is a cognitive act. Hence, creativity in science inevitably must involve unique and consistent cognitive processes and strategies. It does and psychologists of science have concluded that at least four cognitive processes are consistently involved in scientific creativity, namely analogy, metaphor, visualization, and fluency and flexibility of association.

Analogy

‘Analogy’ involves seeing how something new (target) is like something old (source). Our mind seems to do this automatically and intuitively almost any time we are confronted with a new idea or new experience. Analogy is one of the more ubiquitous ways the brain takes sensory experience and gives it meaning. In *The Way We Think*, the cognitive scientists Gilles Fauconnier and Mark Turner put it this way: ‘Analogy has traditionally been viewed as a powerful engine of discovery, for the scientist, the mathematician, the artist, and the child.’

There is a well-developed literature on the importance of analogy and metaphor in scientific problem solving and creativity. The consensual conclusion from this literature is that analogy is a crucial problem-solving heuristic that allows scientists to apply schemas, models, and mental maps from known to unknown domains in order to solve problems. The success and richness of the analogy depend on how deep the similarity is between old and new. Associations no doubt play a critical role in analogical thinking, with the similarity being touched off via an association. In science, these analogies also often serve as the foundation for hypotheses.

Let us look at one of the most powerful scientific analogies in the history of science: Darwin's tree branch analogy and evolution. Species that are more closely related are closer together on a common branch. This branching analogy is used in current taxonomic systems. The branching tree analogy also makes clear that evolution is not a linear progressive process with humans at the apex, as many evolutionists at the time had argued. Rather, evolution consists of many dead ends and extinct species and is simply a process of the birth, growth, and death of species, all going back to one common origin. This was a truly powerful and revolutionary insight: *all life* on the planet is related! Another foundational analogy used by Darwin was the comparison between natural selection and artificial selection seen in human breeding of plants and animals. Indeed, Darwin's first chapter to *Origins* begins with the well-known principles of 'Variation under Domestication,' which lays the foundation for using similar principles in nature in the next chapter, entitled 'Variation under Nature.'

Analysis of historical cases also consistently reports creative scientists often use analogies to solve problems. In their chapter in *Psychology of Science: Contributions to a Metascience*, Dedre Gentner and Michael Jeziorski compared the way two physical scientists (Robert Boyle and Sadi Carnot) used analogies to the way alchemists employed them. They concluded that following particular rules when using analogies (e.g., avoiding mixed analogies, understanding that analogy is not causation) was the key to distinguishing scientific from pseudoscientific reasoning. But Carnot and Boyle had different styles of analogical reasoning: the former relied on a single analogy, deriving principles from it, whereas the latter preferred to work with a whole family of analogies. Similarly, Nancy Nersessian observed that James Clerk Maxwell used analogies iteratively, that is, he constantly modified them to fit his growing understanding of the constraints of the target domain. Michael Gorman has demonstrated that Alexander Graham Bell deliberately 'followed the analogy of nature' and used the human ear as a mental model for his telephone; like Maxwell, he was able to modify this analogy as he learned more about his target domain.

Metaphor

Metaphor is similar to analogy in that they both involve applying similarity from an old source to a new target. In this sense many metaphors are analogies. The essence of 'metaphor' is an 'as if' comparison, thinking about *X* as if it were *Y*. By applying one phrase or idea to another different one that is not literally the same, we again make the unknown known.

As psycholinguists as George Lakoff, Mark Johnson, and Steven Pinker have made clear, metaphors are so ubiquitous

that we often do not even recognize the metaphorical nature of much of our thought. For instance, Pinker gives the following examples of the metaphorical use of *went*: 'the messenger went from Paris to Istanbul,' 'the inheritance went to Fred,' 'the light went from green to red,' and 'the meeting went from 3:00 to 4:00.' Only in the first phrase is 'went' used literally to mean moving from one place to the other. In each of the other instances, 'went' is used metaphorically. Our minds seem well equipped to make such connections and to transfer similarities as a way of understanding the new and unknown.

It is no surprise, therefore, that science is replete with metaphors. Indeed, most major scientific insights have involved some kind of analogical metaphor. Robin Dunbar has pointed out that metaphorical use of language is especially rampant in particle physics and evolutionary biology. Particle physicists refer to the different kinds of quarks as 'top,' 'down,' 'bottom,' 'up,' 'charmed,' and 'strange.' Such everyday common words could hardly be more literally removed from the abstract, unobserved, and probably unobservable quarks, and yet that is part of the joke or pun of the inventors of these terms. Mathematicians also commonly refer to equations as 'beautiful,' or 'well behaved.' Evolutionary biology is also littered with such metaphors: 'the selfish gene,' 'kamikaze sperm hypothesis,' or the 'red-queen hypothesis' (from Alice in Wonderland), just to name a few. I would also point out that computer science is perhaps even more prone to metaphor: 'user-friendly,' 'mouse,' 'crash,' 'boot-up,' 'file,' 'window,' and so on. As Dunbar goes on to argue, however, there is good reason for such widespread use of metaphor in these fields: they are far removed from everyday experience and we simply have no words to describe the phenomena. Therefore scientists have little choice but to either use metaphors or invent new technical terms. Sometimes scientists do the latter, but more often than not they choose the former, and the terms 'strike us' as 'warmer,' and 'friendlier' than technical jargon (note the metaphorical use of these words).

Metaphor and analogy are common in and out of science precisely because they are so useful to hypothesis and theory formation, thought experiments, creativity, and problem solving. They provide useful constraints to solutions to problems by focusing strategies and preventing random and fruitless searches for a solution. Scientists, and especially the best scientists, tend to use them more readily than novices and thereby go down fewer dead ends when trying to solve a problem. Of course, analogies and metaphors offer such cognitive advantage only if they are appropriate and useful. Often the more creative scientists have a feel for (i.e., an intuition for) a good and productive analogy or metaphor. When they are useful, they make problem solving much more efficient than it would be otherwise.

Visualization

Another cognitive strategy or heuristic often used in but not unique to scientific creativity is visual imagery. The historian of science Arthur I. Miller in his book *Insight of Genius* and elsewhere has written at great length about the important role of visualization and imagery in science. After detailing case after case in the history of physics, he summarized his main point about the role of visual imagery in creative scientific thinking: visual imagery plays an important role in scientific creativity

(e.g., Einstein's thought experiments) and in scientific advance, and it can carry truth value (e.g., Feynman diagrams).

Einstein is one of the more noteworthy examples of the importance of visual thinking. The gestalt psychologist Max Wertheimer spent hours and hours interviewing Einstein in 1916 about how his theory of relativity came about, and among other things, Einstein remarked that he rarely thought in words and used words only after the idea came to him so that it could be communicated to others. The physical world after all is made up of objects and the ability to think in images would be of great help in solving physical problems. Visual intuition, to be sure, was crucial for all of Einstein's great insights: imagining himself traveling at the speed of light, imagining himself simultaneously jumping off of a roof and dropping a stone (which led to his insight that gravity and acceleration are relative quantities), and imagining two observers riding on either the northern or southern pole of a magnet. Most of these visual thought experiments occurred in the 20-year period between 1895 and 1915, and by all accounts this was the period of Einstein's singular creative genius. In fact, other physicists such as Richard Feynman remarked on the lack of creativity in Einstein's later life being connected to his decline in his use of visual imagery.

Physics as a whole became less comprehensible when it moved beyond what we observe in everyday life and can easily visualize. Quantum mechanics is the prime example because it deals with matter at a fundamentally different level than the observable Newtonian world. From about 1925 (with the death of Bohr's 'atom as solar system' model) until 1949, quantum physics moved decidedly away from the use of visual images and toward purely mathematical formulations. In Niels Bohr's 1922 Nobel prize lecture, the limitations of his own model were already clear to him:

We are therefore obliged to be modest in our demands and content ourselves with concepts which are formal in the sense that they do not provide a visual picture of the sort one is accustomed to require.

In 1949, however, Richard Feynman was to change this by advancing his graphic 'Feynman diagrams' to explain how subatomic particles interact. As quoted in Gleick's biography *Genius*, Feynman described what he was doing with Feynman diagrams:

What I am really trying to do is bring birth to clarity, which is really a half-assedly thought-out pictorial semi-vision thing. I would see the jiggle-jiggle-jiggle or the wiggle of the path. Even now when I talk about the influence functional, I see the coupling and I take this turn – like as if there was a big bag of stuff – and try to collect it away and to push it. It's all visual. It's hard to explain.

Most recently, string theory has added concreteness to a concept that right now is orders of magnitude away from being observed, namely, 'strings.' Strings are an excellent example of both how visual images and metaphor are used in the construction of scientific theory.

Fluency and flexibility of associations

In addition to the cognitive processes already discussed (analogy, metaphor, and visualization), a number of cognitive traits cluster around creative ability: remote and loose associations,

overinclusive and disinhibited thinking (latent inhibition), fluency, flexibility, novelty and originality. Sarnoff Mednick's theory of remote associations underscores the associational richness of creative thinkers. J. P. Guilford built a theory of creativity around ideational fluency, flexibility, and originality, arguing that creative thinking results from having many ideas (fluency) that cross boundaries and categories (flexibility) and that are novel and original. Hans Eysenck proposed that the defining cognitive characteristic of highly creative individuals, besides at least a moderately high level of intelligence, is their overinclusive and disinhibited thinking. In other words, creative people automatically have a wider range of associations and have difficulty inhibiting associations and focusing on a narrow range of relevant stimuli. For this reason, they score high in what Eysenck called 'psychoticism.' Finally, Dean Keith Simonton, borrowing from Donald Campbell, put forth the chance configuration theory of creativity, which posits that ideational and associational fluency are the foundation for creative thought. In a very Darwinian fashion, ideas are first generated in great number (variation), get combined (chance permutation), and those permutations that are adaptive and useful get selected and reproduced (retention). Just as in biological natural selection, some ideas are adaptive solutions ('hits') and these get selected and retained, whereas others are not adaptive or useful ('misses') and these do not survive. Creative scientists, like all creative people, are able to produce a richer and deeper set of associations, many of which are not useful, but some of which are. These survive and become the foundation for creative ideas in science.

Conclusion

Science would not exist if it were not for the creative ideas of its participants. The psychology of science has empirically addressed and answered the questions of who becomes a creative scientist. The answers provide particular profiles of neural complexity, development, personality, and cognition. This article summarizes these literatures and provides an integrated profile of the creative scientist. For example, the creative scientist compared to the less creative scientist is called to the life of science at a younger age, remains highly productive, is more confident, asocial, flexible, and hostile, and solves problems more often using analogy, metaphor, and visual imagery.

Glossary

Behaviorism Behaviorism is a philosophy of psychology that focuses on human behavior. These observable behaviors can be described scientifically without any discussion of thinking, feeling, or the unconscious.

Correlation Correlation is a statistical relationship between two variables. For example, children usually grow taller as they grow older. We would say there is usually a positive correlation between children's height and age.

Labeling theory Labeling theory originated in sociology and criminology. It is concerned with how our identities and behaviors may be influenced by the terms other people use to describe us. It is associated with the concepts of self-fulfilling prophecy and stereotyping.

Pathology Pathology is the study of disease. In psychology, the term is used to refer to certain behaviors as abnormal and the people who engage in them as mentally ill.

Self-actualization Self-actualization is a term from several psychology theories. It is to realize all of one's potential – to be all that we can be.

Disciplines that Study Creativity

Creativity has been pondered on and written about throughout recorded history. In modern times, discussions of creativity are drawn from psychology and psychiatry in areas of experimental research, testing, and clinical practice; from education in counseling, curriculum development for and classroom management of gifted children; and from sociology and anthropology in areas of change, diffusion of innovation, and the role of the social environment. Additional areas include the teaching and practice of art, literature, music, engineering, business, and the sciences. More recently, the fields of artificial intelligence, neurobiology, and evolutionary biology have addressed the topic.

Education and psychology have many subdivisions in which creativity is addressed. Carl Rogers and Abraham Maslow devoted most of their lives to the study of self-actualization and psychological health. They saw self-actualization as a prerequisite for creativity in any form. Some authors concentrated on tests to measure the gift of creativity; facets of intelligence, creativity, and wisdom; or the characteristics of those who think divergently or are creative. Others look at gifted child and adult development, counseling the gifted on life issues or career problems, or how to educate and manage gifted children in the nation's classrooms. History, with a somewhat interdisciplinary perspective, may speak of progress, historical genius, the geographic distribution of inventiveness, scientific investigation, or paradigmatic shifts. The study of creativity is inherently interdisciplinary.

Along with the variety of disciplines has come a variety of terminologies. Each group has constructed its terminology to reflect the particular use and aspect of creativity applicable to them. Creativity appears to be a core concept that is then interpreted and redefined as a different aspect or application is emphasized by each discipline. Although some authors speak from an interdisciplinary perspective, borrow individual terms from each other, or share terms, each discipline has a tendency to focus on a specific aspect of creativity, and thus use their own particular words or phrases.

Those in the arts speak of imagination, inspiration, and the unconscious. Those in sociology speak of change, the diffusion of innovation, and resistance to innovation. Some authors discuss creativity and resistance to creativity as seen in American culture. Psychology and psychiatry both discuss the role of the unconscious. Psychology and sociology discuss conformity, deviance, and authoritarianism as factors that can inhibit one's willingness to be independent or creative and the role of labeling. They also discuss the tendency of people either to do things better (adapters) or to do things differently (innovators) and the characteristics of innovative organizations.

In short, the language of creativity is far ranging and methodologies stretch across academic disciplines. The study of creativity may be influenced by current events and reflect the scientific method in use at a particular time. However, the concerns have been remarkably constant. These questions are repeatedly addressed:

1. What is creativity?
2. What is the creative process?
3. What characteristics do creative people have?
4. Can creativity be increased?
5. Who should benefit from creativity?
6. Do we really want creativity?

Early Observations

The earliest writing on creativity is found in myths and personal observation, often about the arts. To be creative was to be divine. The Old Testament God, Odin of Norse mythology, Ormazd of Zoroastrianism, and Brahma from the Hindu trinity created because they had divine power. Among the ancient Greeks, creativity was inspired by the Muses who were the daughters of the god Zeus. The idea of creativity as a divine gift has not completely disappeared. Even today, when writers describe an episode of writer's block, they may say that their Muse has left them. Many creative people say that the ability to be creative just happens. They do not know where it comes from. It is a gift.

The Greeks limited creativity to the poets – everything else was using existing materials to make something. Greek writers addressed questions about the creative process. Plato, in the fourth century BCE, observed that necessity is the mother of invention. Epictetus (CE 60) addressed what later writers would call incubation and/or perseverance when he said that there must be time for great things to be created.

Research into creativity did not really begin until the nineteenth century. However, earlier reactions to change can tell us a little about early views of creativity and the on-going tension between change and the *status quo*. Humans have always been as likely to resist innovation, invention, and change as to embrace it. Mohammed's statement that every innovation is an error and every error leads to hell fire stands in dramatic contrast to the fact that the Middle East was a center of learning, famous for hundreds of years for its libraries and universities. Sometimes the stories of early resistance seem almost unbelievable – an English citizen was tried, condemned, and executed in 1306 for burning coal rather than wood. "The textile industry was the first battleground of machine technology against hand tools" (Stern, 1937, p. 55). The conflict started in the thirteenth and fourteenth centuries and continued until the Luddite riots into the nineteenth century. From the time of Philip the Fair (1268–1314) many innovations in transportation have been blocked.

Developments in communication were also blocked. Governor Berkeley of Virginia expressed a widely held opinion in 1670 when he thanked God Virginia had no free schools or printing presses. He believed learning brought disobedience and heresy. Printing made that information available to all and threatened the existing government.

Nineteenth Century Creativity

Before the twentieth century, creativity was usually addressed within discussions of genius, a term which may have originally meant possession by genii, which is reminiscent of the Greek Muses. More formal writing about creativity during the nineteenth century was characterized by a broad, generalist perspective, usually with little experimental basis for its conclusions. Early work was conducted in the study of philosophy, intuition, mysticism, literary criticism, art, invention, and genius.

The authors tended to be generalists, and their work reflected that fact. For example, George Washington Bethune was an American clergyman, poet, musician, orator, and gentleman scholar. In his address to the Literary Societies of Union College in 1837, Bethune defined what he meant by genius, discussed how to increase it, refuted common errors concerning genius, and then concluded with the role of democracy in creativity.

Although few authors presented a formal definition of creativity, such definitions can still be found. These definitions often blur the distinction between intellectual genius and creative genius. Some are based on criteria of newness and importance. Authors also addressed such issues as types of creativity, intellectual components, and the creative process. They presented concepts that are still a major part of

the literature: new combinations, divergence, background knowledge, building on previous work, incubation, illumination or inspiration, and the evaluation of results.

These authors wrote during the nineteenth century ferment of the colonial British Empire, Darwinism, and the development of new scholastic disciplines. It was a time when the scientific method of investigation was still developing. Thus, the authors tended to draw from what today would be considered a combination of disciplines and questionable methodology. Many of their conclusions were based on personal observation. Some conclusions were presented with little information as to the data that prompted them. In addition, there are problems in tracing the sources of these early writers. Because they did not always include footnotes and tended to refer to another's work by last name only, it is sometimes difficult to find their sources or to be assured that the source located is indeed the correct one.

Often these earlier discussions explored the questions and issues in depth. Much of the discussion centered on presenting, defining, and analyzing the questions given above. There was a philosophical wisdom to this early work that disappeared by the middle of the twentieth century, to be replaced by an emphasis on quantitative analysis. While there was a richness to this earlier work, present day scholars would probably say that rigorous methodology was missing from these discussions.

Discussions of who had creativity usually centered on whether creativity was an inherited ability, or whether everyone could be creative. There was a tendency to stress the role of heredity, rather than the environment.

Determining the characteristics of creative people seems to have involved two issues. Were they so different that they were to be considered deviant, and perhaps even pathological? What intellectual characteristics were necessary for creativity?

Discussions of increasing creativity usually centered on individuals or groups. Individuals could increase creativity by developing work habits and thinking styles that would foster it. Group creativity was less clear. Some saw a strong connection between the promotion of individualism or democracy and the creativity of a culture. Others argued over whether times of great creativity were caused by geniuses, or whether the spirit of the times allowed the geniuses to flourish. There was also a strong connection between creative genius and democracy.

During the nineteenth century, there was some explicit discussion of the benefits of creativity. Bethune stressed that the end product of creativity be useful. Genius was a gift from God that should be used in His honor and for the good of all. Those gifted with this God-like power of creation were not to waste it on personal enjoyment or fame.

One might expect that creativity would be embraced during this century of explosive national and industrial development. However, that did not always happen. Sometimes resistance seems almost irrational in the light of twenty-first century technology – the bathtub was rejected in the 1840s because it would corrupt our democratic simplicity. Inventors who worked to develop steam engines and submarines were ridiculed, scorned, and considered insane. Railroads were attacked because money would be needed to build insane asylums when people were driven mad with terror at seeing the

locomotives move without horses to pull them. Railroads were also condemned because the Bible did not mention them. The managing editor of the New York Herald censured his city editor for publishing an article about Thomas Edison's light bulb because it was against the laws of nature.

Some people objected to a proposed 6-month typing class for women in 1881 because the stress would cause women to break down completely. When automatic telephone switchboards were introduced, some leading engineers denounced them. Eminent scientists – and even H. G. Wells who has been characterized as the father of modern science fiction – repeatedly dismissed airplane travel as impossible.

What would cause people to raise objections that in hindsight are so obviously groundless and illogical? Were people trying to be responsible and anticipate the consequences of their actions, based on what they currently knew? That is always difficult to do because it assumes that what is currently known is correct. It is also dependent on how well the author can extrapolate. At the time of the typing class educated people believed women's mental and emotional strength was limited because women had smaller brains than men did. Based on that belief they were proposing a legitimate reason for concern. But to conclude that women who managed families and households could not learn to type without having a nervous breakdown is ludicrous to us now.

Were people simply worn out from too much change that came too quickly? Had the events of the nineteenth century exhausted their ability to cope with change: the War of 1812, the westward expansion, the Civil War, the industrial revolution, several economic depressions, and the beginning of sophisticated technology based on electricity? Or is resistance the normal human response?

Determining what is driving resistance becomes even more difficult when one takes into account the fact that sometimes the objections turn out to be valid. For example, people were concerned about the noxious smoke that would billow from trains and cause health problems. For decades, this fear remained groundless. When Bernard Stern submitted his report to the National Resources Committee Subcommittee on Technology in 1937, he cited this as an example of resistance to innovation. It was just another example of people's silly opposition to change. Decades later when we were overcome with atmospheric pollution, it was no longer a silly concern. Those objections had successfully predicted our new reality.

At the close of the nineteenth century, Théodore Ribot issued a call for further research into creativity. He called for investigation into the development of creativity in children, primitive myth-building peoples, and geniuses. He also called for more rigorous examination of the different types of creativity in all areas – aesthetic, scientific, philosophical, mystical, practical, mechanical, industrial, commercial, and military. It is somewhat remarkable that his request was almost a prediction. Research on creativity has, in general, followed the paths he outlined.

First Half of the Twentieth Century

The literature in the first half of the twentieth century reflected growing academic specialization and developing experimental

techniques. The questions addressed during this time centered on how is creativity defined, who has it, what are their characteristics, and how can it be increased. The effect of the environment and a milieu of opposing forces began to be examined.

A cursory look at the creativity literature during the first half of the twentieth century shows a large amount being done in Europe – in European languages. Topics included the role of inspiration, esthetic behavior, the unconscious, and imagination in the arts. Publications also dealt with productive invention and creation in the sciences. Eliot Dole Hutchinson wrote that as of 1931 German literary criticism contained the most vital discussion of creative ability. Europe was seen as the center for basic creative research. The United States was seen as successful in applied research and development, but fundamental research and the scientific and creative thinkers producing it were often imported from abroad.

When looking for explanations for this apparent lack of American interest in creativity, one could make a case for the fact that the new country had put much of its energy into settling the frontier. One might suggest that they were so busy being creative, they did not have an interest in studying it. One could also mention the impact of American democratic ideals that would tend to make America reluctant to investigate striking differences among its citizens. Europe has had a tradition of extremely high respect for learning and education. The anti-intellectualism, noticed by some writers as rampant in American culture, was largely unknown in Europe. For whatever reason, early in the twentieth century, American study of creativity did not have a strong theoretical foundation.

In the 1920s, imagination and invention began to be investigated in America under the title of creativity. Throughout the 1930s and 1940s there seems to have been a call for creativity, both in industry and in the schools. The discussion of creativity began to be more focused, sometimes more practical, and more concerned with education. It became less philosophical, and more in the tradition of modern psychology. Rather than reflecting the musings of an armchair philosopher, the work began to show the results of experimental studies. While this might be considered to have increased the quality of the work, it also meant that the philosophical wisdom and insights of the earlier period were no longer available, and no longer valued.

The First World War called for a mass mobilization of men and matériel. Men had to be assessed quickly and placed where individual abilities could best be utilized. The testing of individual abilities grew out of this need, which would occur again during the Second World War. The need for creativity can be illustrated by the fact that the employee suggestion system first used in Scotland in 1880 by shipbuilder William Denny was first utilized in the United States by the Navy in 1918.

The massive mobilization of the Second World War included the scientific community as well as industry. The damage done by Germany's rockets, its progress toward an atom bomb, and finally, America's successful development of an atom bomb all highlighted the need for creativity. After the Second World War America's industry expanded, in part, because Europe's industrial ability had been destroyed. Creativity continued to be needed and to be a topic of study.

However, in one of those paradoxes typical of discussions of creativity, war could also reduce the incentive to be creative. High taxes to support the war, pressures generated by unions, and the lack of items such as rubber, silk, and scientific laboratory glassware (which had been manufactured only in Germany) all affected the creative output of the United States. When it was all over many, including social scientists, were appalled and intrigued by the dynamics of the fascist cultures in Germany and Italy. Psychologists began to study areas indirectly related to creativity, such as authoritarianism and conformity.

During this period, most of the critical analysis within the field concerned the quality of the work, and the need for more creativity research. Thomas Knowlson attributed the lack of research to the nineteenth century belief that genius was a gift that needed neither training nor experience. Rollo Walter Brown pointed out the irony of America, which boasted of its progress, also neglecting and stifling creativity – even treating it as a symptom of a grave disorder. In 1931, Hutchinson reviewed the creativity literature, but concluded that it was so small and scattered in so many disciplines, it could hardly be called a literature.

Definitions of creativity during this period usually included criteria whereby something could be judged creative. Also included were discussions of whether creativity is a rational process or a mystical experience beyond examination by the senses or intellect.

Graham Wallas is credited by many as being the first in 1926 to articulate a complete description of the basic creative process. During the first stage, preparation, the problem is investigated thoroughly. Knowledge and intellectual techniques are acquired. The second stage, incubation, is a period when the problem is not being worked on at a conscious level. However, the unconscious continues to work on the problem. The third stage, illumination, is that flash of insight that appears almost as if by magic. The final stage was verification, in which the idea was put to the test, and further honed or developed.

Discussions of who has creativity usually centered on identifying those with creativity and deciding whether everyone could be creative. Some like J. Henri Poincaré seemed to take it for granted that not everyone could invent. Others felt that all had creative ability. This discussion can still be found in the literature.

The testing of creative ability had already begun by the time Guy Montrose Whipple reviewed five tests of imagination and invention in his 1910 manual on physical and mental tests. He saw invention as part of intelligence, and believed that any measurement of intelligence must include the testing of imagination and invention.

Ray Simpson proposed that people could have different forms of creative imagery – visual, auditory, verbal, kinesthetic, or logical. While he struggled with how one could measure the quantity of new ideas, he also wrestled with the issue of assessing quality. He asked whether a typewriter or Rembrandt painting was of more creative significance.

In the early 1920s, Edwin Slosson and June Downey worked to develop a creativity test that would be as accurate and helpful as the Binet intelligence tests were becoming. They hoped to be able not only to identify those gifted with creativity, but also to develop it, and offer vocational guidance.

Discussions of the characteristics of creative individuals usually included physical or psychological traits, and whether or not these were normal. They also often addressed the question of the underlying and necessary cognitive components of creativity.

The idea that the gifted had a more intense interaction with their environment had been mentioned as early as 1902 by William James, and would be echoed by Ruth Strang in 1960. However, in 1938 Kazimierz Dabrowski introduced the term *psychic overexcitability* to describe an expanded and intensified experience in five dimensions. These were: high energy, or excitability in the neuromuscular system; heightened experience of the senses; intellectual; rich imagery, visualization, and impressions; and strong attachments and intense feelings.

More than one author struggled with the question regarding the mental health of geniuses, including creative geniuses. Was genius a normal variation or pathological? Would one characterize the energy that came from those gifted with creativity as an ungovernable desire? That would reinforce the belief that geniuses run amok. Most rejected the idea that geniuses were insane, but they were frequently different, which brought the authors back to the original question: Is different normal? Is different pathological?

Discussions of increasing creativity were often blurred with discussions of the role of the environment. Those that clearly focused on increasing creativity discussed how an individual might increase his or her own creative ability and how schools could increase creativity. Should the schools provide general education or specialized education in creativity itself? Some of these discussions began to address the role of self-actualization.

During the late nineteenth and early twentieth centuries, child-centered education began to be an educational issue. It was an effort to individualize education, rather than ensure adjustment to society for the greater social good. In 1928, Harold Rugg and Ann Shumaker discussed the relationship between creativity and the industrial revolution, creativity in education, and the conflict between creativity and conformity. They saw the mass school in America as a replica of the mass mind of America – a result of 200 years of industrial revolution. Because of the pragmatic and exploitive spirit of the age, those who might have been creative artists were moved into technological development. The role of the child-centered school was to allow creativity to flower. This emphasis on self-expression and growth was an issue that would rise again in humanistic education and in the workplace through the human relations movement of the 1950s and 1960s.

Discussions of the environment looked at the effect of the environment on creativity. Some maintained that creativity would always rise, no matter what the environment. Others argued that only an individualistic, democratic environment with a certain level of prosperity would foster creativity. In addition, the industrial revolution that was allowing American prosperity was seen by some as a spiritual suicide. They believed the dehumanizing conditions in factories and company towns, the boring and repetitive nature of assembly line work, the lack of control over their own lives, and the lack of opportunity for originality robbed the industrial worker of the opportunity to be creative.

When discussing the dynamics of creativity as seen in individuals, groups, and cultures, invention of a visible product was often mentioned. These discussions of creativity, innovation, and invention usually centered on the relationship between the inventor and either a local environment, such as the workplace, or the larger social context.

Some such as Knowlson and Ralph Linton saw only the individual as creative; groups did not create. Inventors were usually rewarded only when the group realized its needs were not being met, or when it was seriously threatened. As a general rule anything too different would be suspicious and bring ridicule rather than prestige.

Linton also defined two types of inventions, both of which build on the knowledge base of the culture: basic inventions that involve new principles and inventions that improve on an existing invention. Basic inventions were frequently little more than a toy or curiosity at first—sometimes considered worthless. He believed that, as a rule, basic inventions resulted from the efforts of conscious inventors, working alone, not as part of institutional invention. For every invention that has been incorporated into a culture there have been many which have been rejected. Linton believed that the same things were invented and rejected repeatedly until changes in the culture prepared a place for them. No society had ever used even a tenth of its inventive ability.

As mentioned earlier, in the late 1930s Stern compiled a historical analysis of socioeconomic and psychological factors involved in resistance to innovation from the early Greeks to the twentieth century. He recounted in detail many instances of rejection. He mentioned patents bought up and held so no one could use them, high service charges added so customers would be less likely to use the new item, and the continued use of hand methods for years after new machinery had been proven effective. In many cases, scientists, engineers, and educated leaders were involved in the rejection.

Bankers refused to lend farmers money with which to buy tractors because the farmer would have too much leisure time. In 1934, prefabricated houses were attacked by the director of the New England division of the American Institute of Architects as causing people to substitute a life of vagrancy for responsible citizenship.

Stern concluded from his historical analysis that resistance to change comes from habit, fear, the desire to maintain the *status quo*, personal status, and the pressures of group conformity. These predisposing factors function within a cultural context, which is affected by economic, political, and religious factors. The strongest of these, economic factors, puts employees at risk. In fact, during times of great economic stress, many countries have requested moratoriums on science and invention. Small, incremental innovations may at that point have the best chance of being accepted. This would be expected, not only because invention builds on previous knowledge, but also because it lessens resistance.

As authors had done in past decades, Stern criticized education in the United States as doing little to help people handle technological innovation. With few people trained to verify data or analyze proof, Americans were forced to rely on expert authority, which Stern saw as being historically conservative and resistant to change.

Second Half of the Twentieth Century: 1950–1985

With the beginning of the 1950s came changes in the study of creativity. Psychologists began to be deeply involved in identifying and understanding creative gifts. As Josiah Royce had spoken on creativity in his address to the annual meeting of the American Psychological Association in 1897, J. Paul Guilford, as president of the Association, addressed it on the same topic in 1950. He had just received a grant from the Office of Naval Research for a project to study the aptitudes of high-level personnel – a project later characterized as the most profound study of creativity ever undertaken. Guilford characterized the neglect of psychological creativity research as appalling – a conclusion voiced by others for years before and after this seminal speech. He cited the concerns of industry and governmental agencies in recognizing and developing creative ability both in leaders and in scientific and technical personnel. Writers in the 1960s credited this speech as providing the impetus for creativity research over the next 12 years. The listings of articles in the academic indices of this time confirm an increase in the number of articles and books written.

During these years, researchers became more focused. For example, some, such as E. Paul Torrance, concentrated on testing for creativity. Others, such as Guilford, looked at the cognitive factors that contributed to creativity.

Definitions of creativity during this time can be illustrated by a matrix (Figure 1). Definitions can be placed along one continuum ranging from a practical, rational, problem-solving technique at one end to an inexplicable event, or beyond examination by the senses or intellect, at the other end. Definitions also range along another continuum between explicit, or clearly stated, and implied.

Some authors addressed the creative process by itself. Most who explicitly described a creative process described one similar to the one outlined earlier by Wallas and Poincaré. It was a four-step process consisting of preparation, incubation, illumination, and verification. A few stages, such as implementation, have been added, as has the likely recursion or recycling through stages more than once.

As Albert Rothenberg and Bette Greenberg pointed out in 1976, the issue of who has creativity involves several questions.

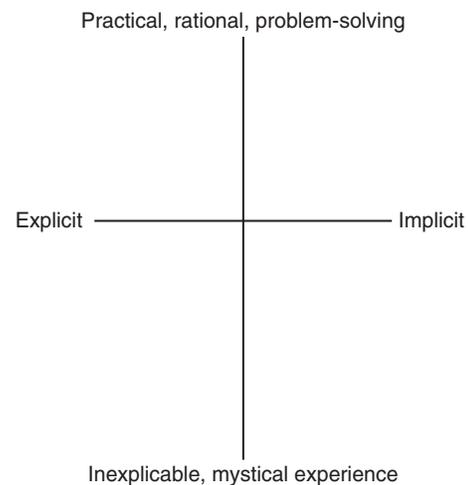

Figure 1 Definitions of creativity.

Is creativity uniformly distributed across the population, with everyone having the potential to be creative if taught and nurtured, or is it a gift to only a few? If everyone is creative to some degree, then what characteristics do those who are most creative have? If only some are creative, and those individuals are different, what are those differences.

Ideas about the distribution of creativity also appear to fall along a dimension with 'only a few are creative' at one end and 'everyone can be creative' at the other end (Figure 2). Again, some authors were explicit in their view; others were implicit, as if they were not themselves sure. Rothenberg was somewhat typical of this in 1970 when he acknowledged that creativity was probably common throughout history, but that true creators were unique.

During this time, many researchers concentrated on the characteristics of highly creative people. Researchers studied children as well as adults, and in fields that ranged from the arts to the sciences. Although the studies varied widely, authors frequently mentioned that creative people seem able to integrate into their personalities many opposing qualities. For example, they appear to be more masculine and yet more feminine; more independent, yet more receptive to suggestions; more playful, and yet more serious. They also seem to be comfortable with the unknown and ideas that were in conflict.

Researchers also began to study cognitive abilities and styles in more depth. Was creativity a part of intelligence? There were correlations between the two, but were these components of cognitive ability or two different abilities?

The question of whether or not those with unusual gifts were normal was asked during this time, as it had been before. Some discussed self-actualizing creativity as a sign of psychological health. Others felt that since high ability was on the edges of normal distribution, it was only reasonable to call it a deviance, and still others saw the behaviors of creative people as indicators of pathology.

In 1978, George Becker termed this the mad genius controversy. He used labeling theory to examine changes in the nineteenth century that led medicine and science to redefine genius as insanity. He concluded that in an effort to differentiate themselves from those less gifted and their artistic predecessors, intellectuals and artists during the Romantic

period (last half of the eighteenth century and first half of the nineteenth century) adopted idiosyncratic behaviors. Many Romantic geniuses may have assisted in a labeling process that worked perhaps too well and they ended up being seen as mad.

Given the political environment at the time, it is not surprising that numerous researchers worked on developing a test of creativity. After all, in order to provide guidance and furnish a supportive environment one must first identify creative people. Theoretically, this could be done through nominations, tests, behavior checklists, and profiles. In terms of practical application, however, it did not materialize. There was nothing that would allow a teacher or manager to administer a 50-min test and conclude that the tested individual was and would be creative in the classroom and office.

Several reasons for this were proposed. There were few creativity theories, methodological problems with previous work, the need for interdisciplinary work, and the need for longitudinal studies using large samples. It was also difficult to evaluate creativity. Judges had difficulties distinguishing creativity from other abilities such as intelligence and achievement. It was even more difficult to discriminate between various dimensions of creativity.

As Dennis Hocevar pointed out in 1981, if each method of testing for creativity actually measured creativity, the methods should have a reasonably high level of correlation. While results based on the same method tended to have high correlations, results from different methods did not. Individuals would be ranked differently on creativity depending on the method used. Were researchers studying different phenomena and did not realize it?

Authors addressed three ways of increasing creativity through the environment: the role of the home and school environment in encouraging the development of creative personalities, the role of instruction and/or reinforcement, and maintaining the general environment so as to nurture higher creativity for all.

Inherent in any discussion of manipulating the environment to increase creativity is the assumption that the environment influences creativity. The three ways in which this might occur all hark back to questions asked in the pre-twentieth century literature: does the environment produce the creative individual, does the creative individual create the environment, or does creativity occur as an interaction between the two?

Amid all the research being conducted on parenting styles, classroom environment, rewarding the development of specific personality traits, and similar topics, two authors stand out. In the 1960s, Arnold Toynbee and Richard Hofstadter both addressed the negative effect American culture had on creativity. Toynbee was concerned that American public opinion valued social conformity. He attributed it to a perversion of democracy that promoted the idea that all inequalities are undemocratic.

While Hofstadter agreed that America has an anti-ability bias, he disagreed with Toynbee's statement that this was a recent development. Hofstadter was strong in his belief that America had never valued it. It had been part of American culture since the beginning of the colonies.

Because creativity involves an unconventional stepping outside normal habit and thinking, sociological studies on

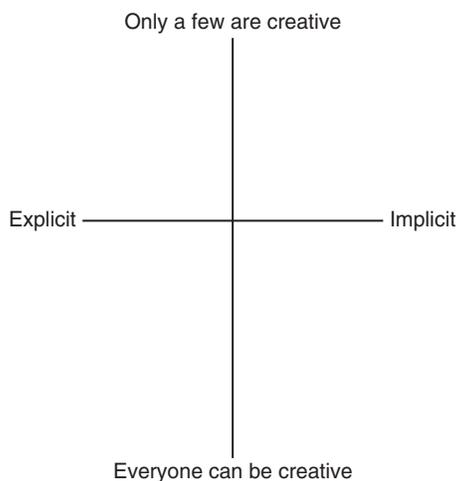

Figure 2 Distribution of creativity.

conformity and authoritarianism provided some insight into the dynamics of noncreativity. What Pauline Pepinsky termed productive nonconformity in 1961 is remarkably close to a definition of creativity – an independence that can make a positive and significant contribution to an individual or group accomplishing a task. She found the characteristics of those who were productively nonconforming to be similar to those found in highly creative individuals. They were independent, spontaneous, and yet had self-control.

Investigators working in the areas of social change and progress explored the differences between those who innovate and those adapt. Others discussed such topics as differences in cultural attitudes and expectations about progress, and what motivates individuals and societies to seek or resist change, and how that resistance manifests itself. Additional topics included tensions between individuals and the group, tensions between competing groups, and how innovations are diffused throughout a culture, or to another culture.

During this time, there was also the beginning of efforts to map the field of creativity, to organize or categorize the body of creativity knowledge into patterns, continua, or matrices. Once again, there was little consensus on how to do that. Should creativity research be categorized by where it was on one of these continua: process versus product, focus of control versus interaction, mystical versus rational, or normal versus pathological? Alternatively, should the classification system be based on cognitive functions of thinking, feeling, sensing, and intuiting? Or was it more important to classify the work by the methodology: theory-based, experimental, psychological testing, interviews, or historical data of famous people? Or was it as simple as the three main focal points outlined by Morris Stein and Shirley Heinze: the individual, the environment, and interactions between the individual and his or her environment?

An implicit theme ran through many of the articles and books, although sometimes it was stated explicitly. It was the idea that creativity was considered a crucial element in winning the cold war. Concerned over an already advancing technological race between America and the Soviets, authors pointed out that the lone inventor of the eighteenth and nineteenth century had been replaced by the industrial research laboratory. They questioned whether the research laboratory could produce the creativity that was needed.

This cold war theme became even stronger once the Russian Sputnik went into orbit in 1957 when all of American education came under attack. The call for creativity became part of the general restructuring of American education. The teaching of children who were gifted both intellectually and creatively became a priority; they came close to being considered cold war resources.

Second Half of the Twentieth Century: 1980 to Present

Although it may be too soon for the distance needed for an historical analysis, there appear to be several characteristics of the literature during this period. The first is that authors are writing two types of creativity articles. In the first, authors or researchers observe creativity, define it, learn to identify it, and then control it. In the second type, authors evaluate or critically analyze the work in creativity.

A second characteristic is the seeming expansion of the human potential movement, self-actualization, and positive psychology perspective that almost seems to have brought us full circle back to a more mystical, meta-physical view of creativity. The third characteristic lies in the development and recognition of creativity theories and models.

The fourth characteristic is the efforts to classify those theories and models into perspectives or paradigms. Although there were writers throughout earlier periods who reviewed available knowledge, the literature during this period reflects growing efforts at critical analysis within the field. More writers are consolidating information, conducting meta-analyses, and proposing classification patterns in how creativity is defined and studied.

The tremendous increase in the use of the internet, as well as its very nature, causes one to ask what its impact will be on creativity. The effect of the printing press on learning and the resulting spread of ideas are well documented. One can only assume something similar will result from the internet. With the internet, the potential for collaboration increases dramatically. In addition, we have access to new ideas more quickly than ever before. We can incorporate the new material into our own developing ideas and build on them. One question more difficult to answer is, what will be the relationship between democracy, the internet, and creativity. That will be an interesting trend to watch over the coming years.

Summary

The range of creativity research is great, covering many different disciplines. It contains many different models, perspectives, or schools of thought. There is still no single, unifying theory of creativity that could be embraced by all researchers and practitioners. Given the complexity of the subject, that may not be possible.

The metaphor of the blind men examining the elephant is appropriate. For almost everything about creativity that someone knows, someone else knows its exact opposite. For example, everyone can be creative; only a special few are really creative. Creative people are a little crazy; creative people are more psychologically healthy. Creative people are very different; they are just like the rest of us. Creativity can be taught; one has it or one does not.

We are still wrestling with whether there is only one type of creativity, or whether it is domain specific. Many are still using the creative process formulated by Wallas in 1926, even though there is some evidence we use it because it feels right, rather than because it has been substantiated by empirical study.

We still ask why some people are more creative than others are. In spite of its political incorrectness, we still wonder if creativity might depend on the physical structure of the brain or genetic inheritance. We have examined the childhood environments of creative people, but we still wonder whether the environment produced the child or the child produced the environment, and whether or not a similar environment in the workplace would increase creativity.

We do know something about the personality characteristics of creative people, but we still have questions regarding the

relationship between these characteristics and creativity. Some investigators almost seem to assume that the characteristics cause the creativity. They recommend changing personal qualities as a way of increasing creativity.

We are not certain whether very creative people have more of these characteristics, or more of only specific characteristics. Where we have obtained the criteria for defining the normal characteristics to which we compare creative people has not been addressed. What has been the role of white male values and definitions in determining what constitutes unconventional behavior? What effect have male values had on those definitions of creativity that stress a rational, problem-solving process? And how have the values of males affected cultural and organizational reactions to creativity?

We also seem to assume that negative qualities are inherent in the creative person. We have not investigated the relationship of societal reactions to the creative individual as a possible causal factor in the development of what is seen as rude, brash, or self-centered behavior.

We continue to disagree over training for creativity. Does it increase creativity, test-taking ability, or only certain aspects of creativity? We know little about its transferability to a task.

We still are not clear on whether a few very creative individuals push a culture toward progress, or whether the culture, its

needs and norms, draws the creativity out of them. The inter-relationship between groups or cultures and creativity continues to be an area of potential study.

After more than 100 years of systematic study, we seem to have defined the basic issues or topics of creativity research. Somewhat surprisingly, they appear to be the same questions asked during the beginning of that study in the nineteenth century.

Creativity Training

J J Caughron, D R Peterson, and M D Mumford, The University of Oklahoma, Norman, OK, USA

Using Training to Increase Creative Thinking

Creativity has been linked to many outcomes people generally find desirable. Cropley published work in 1990 suggesting creativity can be linked to helping individuals adapt to the rigors of daily life. Mumford and Moertl in 2003 argued that the development of new social institutions can be linked to creative thinking. Similarly, Simonton suggested in 1999 that organizational survivability can also be linked to creative work by organizational members. Furthermore, several researchers such as Enson, Cottam, and Band in 2001 and McGourty, Tarshis, and Dominick in 1996, suggested that creativity will continue to be increasingly important as information becomes more readily available and jobs become progressively more complex. As such, it is not surprising that researchers have not only studied creativity extensively but have also tried to increase people's creative capacity using a number of approaches. These interventions have taken the form of offering incentives or rewards for being creative, helping people gain knowledge or expertise in a given area of interest, or working to create an organizational climate conducive to creative work. However, one intervention that has shown particular promise is training people to be creative, as demonstrated by three meta-analytic works published by Torrance in 1972, Rose and Lin in 1984, Scott, Leritz, and Mumford in 2004.

A Brief History of Creativity Training

In their 2004 meta-analysis of training effectiveness on creative outcomes, Scott, Leritz, and Mumford synthesized a wide range of creativity definitions throughout the academic literature to define creativity as the production of useful, novel products or ideas. As such it has been viewed by many to be an important contributor to individual and organizational performance. This is especially true when the environment is one that presents a series of challenging, novel, or ambiguous problems. While this definition of creativity may be generally agreed upon, approaches for increasing an individual's ability to be creative vary widely. Many forms of creativity training have been created for various age groups, from young school children to adults, and for a wide variety of purposes, from strictly educational training to field specific professional training. In a 1998 review of creativity training Smith identified 172 techniques that have been used to develop divergent thinking skills, a cognitive process known to be closely related to creativity. Further, Bull, Montgomery, and Baloché in 1995 identified 70 training techniques that were considered important components of creativity training in their investigation of college level creativity courses. Given the number of unique techniques and instructional methods identified in these studies it is not surprising that creativity training programs vary widely in course content, method of

delivery, intended outcomes, and the theoretical approach used to promote creativity.

Fortunately, researchers have examined the existing creativity training courses and have identified several variables that promote effective training for creativity. Three primary sources provide us with comprehensive examinations of creativity training effectiveness. One of the earliest attempts to comprehensively review findings bearing on creativity training was work done by Torrance in 1972. In Torrance's assessment of 142 studies, it was found that 72% of the training interventions examined achieved the objective of promoting creativity as defined by those conducting the study. While this work provided a good starting point for the comprehensive examination of creativity training, it was subjective in nature and thus was subject to certain limitations. Two limitations are of primary concern. First, given that the criteria for success Torrance used was meeting the objectives laid out by the researchers conducting the study, there was no standard metric for assessing improvements in creative performance as a result of the training intervention. Second, Torrance's work was not quantitative in nature. Expert reviews of literature can offer important insight into a topic, but also leave the door open for subjective criteria to slip in unannounced. This could be of particular concern here given that 103 of the 142 studies reviewed by Torrance used the Torrance test of creative thinking as their primary criterion measure.

In order to address these concerns, Rose and Lin conducted a quantitative review of creativity training in 1984 using a meta-analytic technique. These researchers identified 46 studies in which creativity was measured using a standardized format. Specifically, they only used studies that measured creativity as fluency, flexibility, originality, and elaboration using the Torrance tests of creative thinking. Analysis of these studies provided further evidence that creativity training is effective across all four criteria of fluency, flexibility, originality, and elaboration, but that gains for originality were somewhat larger than for the other three creativity criteria.

The most recent review of creativity training effectiveness was conducted by Scott, Leritz, and Mumford in 2004. In addition to addressing concerns about the age of the prior work by Rose and Lin in 1984, these researchers aimed to identify specific aspects of creativity training that make a course more or less effective at enhancing performance on a variety of creativity-relevant criteria. Specifically, these researchers examined the theoretical approach used by course designers, the content of the course materials, the way in which that content was delivered, and the way in which creativity-relevant outcomes were measured. Knowledge about the effect of the theoretical framework of the course designer, course content, course delivery, and creativity criteria used could provide a more fully developed foundation upon which to draw inferences about existing courses and develop new ones.

Training Variables

Taken together, the subjective review by Torrance in 1972 and the systematic reviews by Rose and Lin in 1984, and Scott, Lertz, and Mumford in 2004 suggest that training is a useful tool for increasing an individual's ability to be creative. In the most recent review of the literature, that is Scott, Lertz, and Mumford's 2004 meta-analysis, researchers examined the effect of training on several creativity related outcome variables. These researchers classified the outcome variables of 70 creativity training studies into four groups: divergent thinking, problem-solving, creative performance, and attitudes towards creativity. These researchers also calculated a composite score of overall creativity based on scores from each of these four more specific outcome variables. They found that each of these outcomes can be increased significantly as a result of creativity training. However, the relationship between training and each of the creativity outcomes identified was complex.

Creativity Outcomes

Divergent thinking is one of the most well-studied aspects of creativity. In the 1950s, J. P. Guilford and his colleagues defined it as the ability to generate multiple alternative solutions to a given situation or problem. Although researchers still debate whether or not divergent thinking is necessary and sufficient for creativity, what is clear is that divergent thinking is a unique capacity that contributes to many forms of creativity.

One of the best known training programs is the Purdue Creative Thinking program. This training intervention was designed by Feldhusen and colleagues in the early 1980s and consists of 28 lessons on audio tape. Trainees listen to 30 minute instructional sessions and work through a series of exercises for each session. The goal of the course designers was to enhance the fluency, flexibility, originality, and elaboration of trainees' responses during creative thought.

As discussed by several creativity researchers since the development of the divergent thinking construct, creativity can also be thought of as the generation of novel, useful solutions to problems (i.e., problem-solving). Problem-solving is defined the act of resolving a complex, ill-defined problem using new ideas that have been developed using multiple pieces of information and expertise in order to provide a framework for implementing a solution. This represents a more extensive description of the processes contributing to creative thought than divergent thinking alone. Rather than emphasizing one process such as divergent thinking, researchers using this approach have identified a wide variety of cognitive processes contributing to creativity. Problem finding, conceptual combination, and idea evaluation are only a few processes that have been identified as being important contributors to the creative process.

The problem-solving approach to creativity spawned a well-known training program called the Creative Problem-Solving program. This program was developed by Sidney Parnes and colleagues during the 1970s and presents trainees with six stages of creative problem-solving. These six stages include mess finding, problem finding, information finding, idea finding, solution finding, and acceptance finding. This course was conducted as a lecture along with a discussion of the

model presented to trainees. Trainees then completed a set of exercises to practice the techniques they learned during training. Evidence bearing on the effectiveness of this program can be found in Reese, Parnes, Treffinger, and Kaltsounis in 1976 and Basadur, Graen, and Green in 1982. These researchers found gains in divergent thinking on a variety of tasks including social problem-solving and planning. Basadur, Graen, and Green stated that engineers in an industrial organization showing significant improvements in problem finding and problem-solving immediately after training and this finding held 2 weeks later on work related measures.

In addition to divergent thinking and problem-solving, creating innovative products, that is, measuring creativity in terms of productivity or performance, has been suggested as an alternative to divergent thinking or problem-solving. One benefit of using performance as a criterion for creativity is that performance is ultimately the outcome of primary concern in real-world settings. Spending time and energy to solve problems or engage in cognitive processes such as divergent thinking do not amount to much in the real-world if nothing is ever produced. Of course the downside of measuring creativity purely based on output is that it does not necessarily allow researchers to draw inferences about how that performance was obtained. However, it is clear is that a person's productivity is an important aspect of their creative performance and should be included in an examination of the effectiveness of creativity training.

Lastly, assessing an individual's response to creative work or examining the degree to which an individual accepts or even initiates creative action is an important aspect of creativity that should be examined. Members of organizations often approach creative ideas with skepticism or even resistance. While creative ideas are often the precursor to progress, they also indicate that change is needed and change often has its enemies. Pair this with the fact that creative ideas do not always work out as intended, it is not surprising that people have difficulty accepting creativity. However, assuming creativity is needed, and given that this article is focused on promoting creativity through training, it is valid to consider the degree to which creativity training helps people become more accepting of creative ideas.

Components of creativity training courses. Training courses can be thought of as being made up of four primary components: the design of the course, the content included in the course, the way course content is delivered, and the media used during instruction. Additionally, the theoretical framework a course designer used in developing the course is likely to have a pervasive influence on all four of these factors.

Course design includes the length of a creativity course, the types of practice opportunities trainees are given (if any), and how the different training sessions are scheduled (i.e., massed versus distributed). Course content includes the factual and conceptual knowledge about creativity the instructor attempts to communicate to the trainees but also includes the types of techniques the instructor promotes for increasing creativity. Course delivery includes variables such as how long the training lasts, the amount of lecture used, the amount of practice time given to trainees, the nature of the practice exercises, the amount of feedback provided to trainees, as well as other variables related to how the instructor communicated material

to trainees in order to facilitate learning the content incorporated into the course. Delivery media includes the types of materials that were used to convey material during the course. The use of lectures, A-V equipment, case-based material, or cooperative learning activities fall into this category.

Effective Creativity Training Interventions

Course Content

Theory

The fact that there is such a wide array of creativity training techniques suggests that course designers have approached creativity training from a variety of theoretical perspectives. This fact has important implications for creativity training in that the theoretical lens a course designer uses to understand creativity can have a pervasive influence on the type of course they develop. The way in which a course designer understands creativity influences the way creativity is defined and the types of interventions and information the designer believes will promote trainee creativity. Not only does this have implications for how creativity is measured in trainees, but it also has wide-ranging implications for the specific content a course designer incorporates in a training course and the way in which that material is presented.

Researchers have used a variety of theoretical approaches to study creativity. Not surprisingly, the use of different theories has led researchers to suggest and explore many different variables as contributors to creativity. This includes affect, organizational climate, psychological disorders and impairments, intelligence, disposition, and cognition just to name a few. Not all of these theoretical frameworks offer clear direction for designing a creativity training course. In 2004, Scott, Leritz, and Mumford classified existing creativity training courses according to the theoretical framework used and examined them in terms of their relative effectiveness in promoting creativity. They found that training based on a cognitive framework of creativity was the only one to yield consistently positive effects.

According to Baughman and Mumford's 1995 work, the cognitive view of creativity emphasizes how individuals use cognitive strategies to process information and work with their existing knowledge to be creative. A creativity training course developed from this framework would be expected to emphasize the use of knowledge and information, focus on the cognitive processes creative individuals use to work with that knowledge and information, and encourage purposeful thinking and action.

There are several reasons why a cognitive framework for creativity should prove useful for developing creativity training. First, a cognitive model of creativity encourages course developers to emphasize specific knowledge structures and provides direction for using that knowledge. Second, unlike dispositional or associational models of creativity, a researcher using a cognitive framework is more likely to focus on more trainable variables such as information gathering, idea generation, idea evaluation. That is, given that dispositional approaches focus on individual differences which are enduring traits and associational approaches emphasize processes that occur outside of one's own awareness, a researcher using a cognitive framework is more likely to focus on variables that are teachable when developing a creativity course.

Not only did Scott, Leritz, and Mumford find that courses developed from a cognitive theoretical framework were more effective than other approaches, they also found that courses that stressed specific cognitive processes during training were particularly effective. Specifically, emphasizing the processes of idea generations, problem finding, and conceptual combination proved to be especially helpful to trainees. It would appear that providing trainees with guidance about how to work with the knowledge and information they have about a problem is one important element of effective creativity training.

With regard to other theoretical approaches showing a lack of effectiveness, or worse a decrement in creative performance, there are two possible explanations. First, these approaches to understanding creativity are fundamentally flawed and do not provide useful framework for understanding creativity. Second, these approaches do offer value for understanding creativity, but do not emphasize constructs that can be taught in a creativity training course. Future work in these areas could help resolve this issue.

Processes

The cognitive processes individuals use as they do creative work are potentially key components of a creativity training course. A great deal of research has focused on identifying the cognitive processes people use when they do creative work. This can provide course designers with a wealth of information regarding the types of constructs to be addressed in a creativity training course. Given that cognitive frameworks have proven to be the most effective theoretical background for designing creativity courses it is important to consider the specific cognitive processes these courses emphasize. This can provide us with a better understanding of how effective emphasizing each of these processes is and whether or not some processes are better for some outcomes and worse for others.

In Scott, Leritz, and Mumford's analysis of creativity courses, it was found that programs emphasizing the process of problem identification were very effective for promoting general creativity. Upon closer inspection, problem identification training is especially useful for promoting positive attitudes towards creativity, problem-solving ability, and creative performance. It is also helpful for promoting divergent thinking, although the gains for divergent thinking are much more modest than the gains in problem-solving, performance, and attitudes. When one considers that divergent thinking is the process of generating multiple outcomes or solutions to a given situation it is not surprising that it is not impacted greatly by encouraging trainees to identify problems effectively. Similarly, given that problem identification involves the detection of environmental circumstances that can hinder progress towards a goal it is not surprising that it is helpful for promoting problem-solving ability and creative performance. The reasons behind the positive relationship between problem identification training and attitudes towards creativity may be less obvious. However, it is likely that helping people identify problems allows them to be more proactive in dealing with problems and can give them a sense of empowerment for dealing with their environment. Future research on the nature of this relationship can do much to clarify why problem identification training promotes more positive attitudes towards creativity.

Training emphasizing information gathering showed a more complex relationship with creativity related outcomes. Its effect on general creativity was negligible; however, trainees receiving information gathering training showed modest gains for problem-solving ability and notable gains in creative performance. Interestingly, information gathering training seemed to depress trainees ability to engage in divergent thinking. Information gathering helps individuals identify critical causes, relevant contingencies, limitations in resources, and emergent problems or goals inherent in a given set of circumstances. As such, information gathering is an important part of creativity as it is manifested in more applied settings, settings in which problem-solving and creative performance are more likely to occur.

The finding that training participants to gather information does not help them with regard to divergent thinking may at first blush seem paradoxical. Gathering more information might be expected to help trainees develop a wider variety of solutions. However, if information gathering helps trainees recognize that the issue they are facing is nested within a given situation, it is likely that solutions that fall outside of the given situation will not be considered. Thus encouraging information gathering may have positive effects for some creativity related outcomes and inhibitory effects for others. Given these findings it is likely that information gathering helps individuals focus on factors that are directly relevant to a given problem, but also act as a set of blinders that limit the individual's ability to consider 'outside the box' solutions. Future research could help clarify the role information gathering plays in promoting creativity.

Information organization, conceptual combination, and idea generation represent processes in which individuals work with information they have gathered along with their existing knowledge base in order to gain a clearer understanding of their situation, look for meaningful patterns, and begin forming ideas about how to deal with a given set of circumstances. Each of these processes demonstrates a very straightforward set of effects. They are beneficial for divergent thinking, problem-solving, performance, attitudes toward creativity, and creativity on a general level. This is in-line with many studies that suggest creativity is a cognitively engaging activity requiring high levels of active cognition. Here we see that this active cognition is, at least in part, due to working with information and knowledge and training emphasizing organizing and combining information and ideas is helpful for promoting a wide range of creativity related outcomes.

Another rather complex set of findings emerges when one examines the relationship between training emphasizing idea evaluation and specific creativity outcomes. On a general level, training for idea evaluation does not appear to encourage trainee creativity. This same finding holds for divergent thinking – training individuals on idea evaluation has little discernible effect on their ability to engage in the creation of multiple potential outcomes or solutions for a given situation. However, trainees who receive training on idea evaluation were found to perform much worse on creative performance measures but much better on measures of problem-solving and their attitudes towards creative efforts were more positive.

Idea evaluation is arguably one of the most neglected cognitive processes known to be related to creativity. It is likely

that the mixed findings with regard to idea evaluation's effect stem from a lack of understanding regarding this process. In 1989, Hennessy found evaluation to have an inhibitory effect on creativity. Similarly, Conti, Amabile, and Pollak in 1995 found that individuals who expected to be evaluated were less creative than those who were not expecting to be evaluated. Alternatively, in 2003 Mumford, Connelly, and Gaddis found support for the notion that a leader's idea generation can be stimulated by evaluative processes.

This is truly a puzzling set of findings that future research could do much to clarify. It would be beneficial to investigate whether or not encouraging idea evaluation should be done in some situations and not others or during certain phases of the creative thinking process and not during other phases. It is likely that idea evaluation can hinder the progress of viable ideas if that evaluation comes at a point in time when that idea has yet to be fully developed. Alternatively, promoting idea evaluation may be likely to promote the refinement of ideas or the selection of ideas when one is engaging in problem-solving. Similarly, ones attitudes and behaviors towards creative ideas might improve when they have been given strategies for evaluating those ideas. However, we hasten to add that these are speculative suggestions and future research to examine the effects of promoting idea evaluation should be conducted.

The final variables of interest regarding training cognitive processes are implementation planning and solution monitoring. Training for implementation planning and solution monitoring, two processes that occur rather late in the creative thinking cycle, have both shown sizable positive effects for problem-solving, performance, and attitudes. They showed more modest effects for divergent thinking, which is not surprising given that divergent thinking is a process that typically comes into play in the early or middle phases of creative thought when generating ideas is of more value.

Techniques

Creativity courses can offer a wide variety of techniques or strategies to trainees in the hope of promoting creative thought. Techniques that provide trainees with guidance on how to analyze problems using heuristics or strategies can provide valuable information for a relatively low cognitive cost. Giving people structured mechanisms to identify and analyze critical causes, outcomes to avoid, contingencies to monitor, and other problem specific variables is likely to be extremely effective in promoting creative thought. Alternatively, semi-structured or non-structured techniques are likely to be less effective because they provide little specific guidance and do not help reduce the cognitive load inherent in dealing with a novel, complex, and ambiguous set of problematic circumstances.

In examining the different types of techniques in use in creativity training courses, researchers found that trainees receiving convergent thinking training tended to improve in their overall creativity. Interestingly, the most notable gains were for problem-solving and attitudes towards creativity while a sizable negative effect was found for creative performance. Convergent thinking is a technique that encourages individuals to bring together disparate pieces of information in attempting to solve a particular problem. As such it is not surprising that convergent thinking training would have a large, positive effect on problem-solving. Attitudes may also be

increased because convergent thinking is a relatively simple technique that enables individuals to tackle difficult problems.

The finding that convergent thinking training had a negative impact on performance may at first be puzzling. However, when one considers the nature of convergent thinking it becomes apparent that it is a technique that is more appropriate for solving problems that have a clear and distinct correct solution. In a performance domain there are often multiple potential solutions. While some solutions may have advantages over others, performance is largely an issue of selecting an appropriate solution and then managing the weaknesses of that solution. One's ability to manage those weaknesses is an important factor in the development and selection of a problem solution.

Constraint identification was a technique that had relatively straightforward effects. It was effective for promoting general creativity as well as divergent thinking, problem-solving, performance, and attitudes. It is likely that encouraging trainees to identify constraints has beneficial effects for a number of reasons. First, identifying constraints is likely to help trainees narrow their thinking and in this way might actually stimulate a directed search rather than an less fruitful undirected search for information as the individual engages in divergent thinking. Second, problem solving and performance are two creative domains that primarily measure practical outcomes stemming from creative thought. The identification of constraints that must be attended to when solving a problem or performing a creative act is essential to the success of the effort. Should critical constraints be overlooked a potential solution is apt to fail because it cannot be implemented in a given set of circumstances or important aspects of the problem were not effectively addressed. Third, and lastly, identifying constraints helps individuals evaluate creative ideas. A problem solution that does not address critical constraints is obviously inferior to one that does address those constraints, thus is it likely that an individual's attitudes about working with creative ideas will improve given that are better able to select ideas that are more likely to have a successful completion.

Researchers also found that training emphasizing identifying strengths and weaknesses was beneficial for promoting divergent thinking and attitudes towards creativity. However, trainees who received training in this technique showed decrements in their creative performance. This complex set of findings related to identifying strengths and weaknesses suggests that further research on this technique is warranted. It could be that attending to the strengths and weaknesses of a course of action takes an individual's attention away from the problem at hand and forces them to focus on the plan rather than the problem, thus resulting in negligible effects on problem-solving ability and negative effects on performance. It could also be the case that encouraging trainees to focus on strengths and weaknesses induces a 'paralysis by analysis' in which individuals do nothing because they see obvious flaws with any course of action they could choose. While these are viable explanations, until further research is done on this technique the reason it has such a complex effect on creativity remains unclear.

The use of analogies is a fairly common technique in creativity training interventions. While its effectiveness on an overall level was found to be negligible, it does have some benefit

for promoting creative performance. The value of identifying an analog stems from the fact that knowledge from a similar case can be applied in a new situation. This can help the individual avoid unforeseen problems because similar problems were identified from the analog. Strategies that were unsuccessful in the analog can be avoided while successful strategies used in the analog can be selected. Additionally, using an analog can help an individual anticipate emergent opportunities or problems because they are suggested by the analog. The only real question for further research here is why aren't analog's shown to have larger effects than have been indicated thus far? It is likely that the value of using analogies in creative efforts depends upon identifying analogs that are substantively similar to current circumstances rather than using analogies that are similar only in surface features. Investigating how training can be used to help individuals identify the most useful analogies and to fully exploit the knowledge contained within them could be very useful.

Brainstorming, a technique in which trainees are taught to generate ideas without immediately evaluating them has been a historically popular method for stimulating creative thought in groups. However, Scott, Leritz, and Mumford found that this technique was marginally effective in promoting overall creativity. The largest gains were for attitudes towards creativity and more modest gains for problem-solving. Interesting, negligible effects for divergent thinking and performance were found. Given the popularity of this techniques it may be surprising to learn that it is actually not that effective. However, Mullen, Johnson, and Salas' 1991 meta-analytic review of findings regarding brainstorming would tend to support these findings. Using quantitative and qualitative measures of creative outcomes, these researchers found that brainstorming groups show large and consistent productivity losses compared with others working alone.

The fact that the brainstorming technique does not show larger effects on problem-solving and performance is interesting, especially when one considers that these techniques are often encouraged in applied settings where problem-solving and performance are highly valued. Future research on these techniques is warranted given that the evidence thus far casts their effectiveness on a practical level into doubt. However, the data here suggest that this technique could be quite useful for encouraging people to respond positively to new ideas. Exploring the relationship between brainstorming techniques, peoples' attitudes towards creative efforts, and organizational climate for creativity could be a useful line of research.

The use of less structured techniques such as imagery, metaphors, and expressive activities was found to be detrimental to overall creativity. Some might consider this a surprising finding. Upon closer inspection of the specific creativity outcomes assessed by Scott, Leritz, and Mumford the picture does not improve for these techniques. Trainees given instruction in imagery and metaphors actually showed sizable reductions in divergent thinking, problem-solving, and attitudes towards creativity. Training in expressive activities led to large decrements in problem-solving and performance and a more modest decrement in attitudes towards creativity. It is likely that the less structured nature of these more exploratory techniques limits their usefulness as interventions to promote creativity in a training course. Further research might find creativity-relevant

outcomes that these techniques promote, but the evidence gathered to date suggests that they are not effective interventions in creativity training courses.

Course Delivery

How the content of a course is delivered can have a significant impact on how well material is retained and applied by trainees. The length of the course, the nature of trainee activities, the technology used to communicate information, and the presentation method used by instructors are all course delivery issues that could impact the effectiveness of a training course on creativity.

Design

In line with findings suggesting that time on task contributes to learning and performance, the amount of practice trainees engaged in, as well as the number of minutes of course instruction showed beneficial effects on general creativity. However, the effects for divergent thinking were marginal at best. The findings for problem-solving, performance, and attitudes were sizable and positive.

Another variable that was shown to have a sizable effect on creativity training was the use of creativity models. Training courses that used a specific model of creativity rather than an ad hoc assembly of various techniques were far more effective in promoting trainee divergent thinking, problem-solving, performance, and attitudes towards creativity. The strongest effects were for problem-solving and attitudes, although the effects on divergent thinking and performance were still notable. It is likely that using a variety of independent techniques does not give the trainees a framework for developing a coherent understanding of creative work. Attempting to use a potpourri of more or less random techniques does not facilitate a focused and coherent analysis of a problematic set of circumstances, thus it is not altogether surprising that using a model of creativity can provide a unifying conceptual framework for understanding creativity.

One example of using a specific model to promote creativity training can be found with the use of the Creative Problem Solving (or CPS) framework originally proposed by Osborn in 1952. This method of providing creativity training has gone through at least six major revisions (Isaksen and Treffinger in 2004); however, the same basic components remained. The most recent version of the model consists of framing problems, constructing opportunities, exploring data, generating ideas, developing solutions, and building tasks (Isaksen, Dorval, and Treffinger in 2000). Over 50 impact studies have been conducted on the use of this model in creativity training, providing a robust body of research suggesting it is effective for promoting creative problem-solving in children, young adults and adults. Similarly, this training has demonstrated its effectiveness in work settings as well as educational settings (see Isaksen and Treffinger).

Interestingly, the use of domain specific exercises had a negligible effect on overall creativity. However, the use of domain specific exercises has a sizable, positive effect on performance and attitudes towards creativity. It is likely that by using domain specific exercises trainees begin to see the possibility of using creativity to solve real-world problems they face and as

a result become more favorably predisposed to creative ideas. Additionally, performance in many areas depends upon expertise in domain specific concerns. It is likely that creativity training that emphasizes domain specific application is going to be perceived as being more relevant but also will give specific techniques for enhancing creativity in that domain. Further research on the effect of domain specific creativity training is warranted, especially in light of the fact that its beneficial effects did not generalize to other creativity outcomes such as divergent thinking or problem-solving.

Training courses using realistic practices exercises and materials the trainees consider challenging are highly effective in promoting problem-solving, creative performance, and attitudes towards creativity. Although they were much less effective in promoting divergent thinking, the relationship was still moderately positive. Given that divergent thinking is a more abstract and general outcome related to creativity it is not surprising that activities that give trainees the opportunity to develop their skills in a concrete, realistic fashion do not do much to enhance divergent thinking.

In examining the difference between training programs that were massed versus those that were distributed it was not surprising to find that distributed training was more effective. Distributed training was especially beneficial for problem-solving and performance. These findings are in line with the findings of Donovan and Radosevich in 1999. In their meta-analysis of distributed practice techniques they found that providing longer rest periods between training sessions was very helpful for the acquisition and retention of complex material. To be certain, training individuals to be creative represents a complex task.

Delivery media

Another aspect of training that is important to consider is the type of media trainers used when delivering the training. As technology for displaying information advances a wider variety of delivery methods is becoming available. It can no longer be taken for granted that a training course has a lecture component. Some training programs rely predominantly on video or computer based instruction.

With regard to creativity training, two types of materials stood out: lecture and case-based materials. Both of these techniques were effective for promoting general creativity but also for divergent thinking, problem-solving, performance, and attitudes towards creativity. Further research could do much to clarify why lecture and case-based materials are so effective in promoting a wide variety of creative outcomes. However, a few speculative comments could be made regarding these two delivery methods. Creativity is a particularly complex topic and is rooted in the application of cognitive strategies for finding and implementing novel, useful ideas. Providing instruction in a lecture based format gives trainees a noteworthy advantage over self-paced interventions – it gives trainees access to an expert on the topic rather than forcing them to rely on developing that expertise alone. Thus lecture has the advantage that an expert can provide a depth of coverage that nonlecture materials cannot provide and trainees have the opportunity to ask questions in a lecture based format that would be difficult to ask in other formats. This may be particularly important for training creativity given its complex nature

and that it must be applied in real-world, domain specific circumstances.

The benefit of using case-based materials likely stems from the richness of information provided in materials of this type. Case-based material in creativity training courses typically describes and analyses a past situation in which an individual or a group of individuals have had to use a creative idea to accomplish a goal or overcome an obstacle. A wealth of information can be drawn from past scenarios because they are embedded within real-world circumstances that allows individuals to gain a more complete understanding of how creative work is done, likely contingencies to monitor, the likelihood of success, and the possible side-effect of putting a novel idea into action.

Cooperative learning materials were the only other media type to have noteworthy effects on trainee creativity. The evidence gathered thus far suggest that cooperative learning is most effective for promoting problem-solving outcomes. It is likely that the social exchange between trainees during cooperative learning helps individuals see problems from alternative perspectives and learn by seeing others apply the knowledge they have acquired during the course of training. Much more research could be done to further examine the relationship between cooperative learning and its effect on creativity training. Evidence for how cooperative learning helps or hinders peoples' attitudes towards creative ideas does not exist. Additionally, it is likely that cooperative learning is important for helping trainees learn some creativity related cognitive processes but may be less effective for others. Examining these issues could have an important impact on designing and delivering creativity training in the future.

Conclusion

Systematic reviews of literature on creativity training demonstrated that using training to improve creativity can be highly effective. Using a cognitive approach in the development of creativity training was the only approach that consistently contributed to the effectiveness of creativity training. Specifically, training that emphasizes idea generation, problem finding, conceptual combination, and idea generation were particularly important for promoting creativity.

In addition to characteristics that promote a systematic, cognitive approach to creativity, scholars have also identified delivery methods that appear to promote creativity. Making sure training materials are challenging, include real world, domain-specific exercises, and cover well-researched cognitive models of creativity in an in-depth fashion should promote trainee creativity. Training should involve some lecture-based components along with multiple opportunities for practice by trainees. Naturally, training that involves an in-depth, theoretically based consideration of creativity along with multiple opportunities for trainee practice on challenging, realistic,

domain-specific exercises is likely to be somewhat lengthy. In fact, lengthy training sessions have been found to be associated with higher levels of creativity.

When designing creativity training, incorporating elements that have been shown to promote trainee creativity that have been examined empirically and systematically is likely to enhance the effectiveness of creativity training. Investigating the use of techniques that are less structured like brainstorming or the use of imagery may be interesting, but should be avoided when designing creativity training courses, at least until the real utility of these techniques can be determined. It is our hope that this brief review of findings regarding creativity training has given the reader confidence that training to enhance creativity can, in fact, have notable effects. Additionally, we hope this effort has also informed the reader of specific topics and techniques that when used in creativity training courses can be effective in promoting creativity generally as well as specific aspects of creativity such as divergent thinking, problem-solving, performance, and attitudes towards creative efforts.

Glossary

Actus reus An illegal act.

Anomie The weakening of social norms. When anomie exists in a society, a person has few guidelines for socially appropriate behavior.

Beccaria, Cesare An eighteenth century Italian philosopher who argued that crime could be controlled by punishments only severe enough to counterbalance the pleasure obtained from them; creator of the idea that the punishment should fit the crime.

Consensus view of crime The belief that the majority of citizens in a society share common ideals and work toward a common good and that crimes are outlawed because they conflict with the rules of the majority and are harmful to society.

Diminished capacity Mental impairment less severe than insanity.

General intent The intent to commit the *actus reus*.

Labeling theory Society's response to crime defines some people as criminals.

Legal insanity The inability to distinguish between right and wrong.

Paradigm term popularized by Thomas Kuhn A paradigm is a collective, socially shared schema and serves to explain phenomena until replaced by a better paradigm.

Pendulum swing The alternating emphasis on crime control and due process in the history of criminal justice.

Recidivist Repeat offender.

Zeitgeist The tone of the times.

Types of Criminality

Creative ideas can be sharply divided between those that are warmly and enthusiastically embraced by the majority of persons, and those that are considered dangerous by some invested group or groups. Albert Einstein's theory of relativity is an example of the former type. Einstein became an instant celebrity upon the promulgation of his theory. His name became an analog for genius. Galileo's idea that the Earth was not the center of the universe is an example of the latter. After recanting his theory, the tribunal of the Inquisition sentenced him to house arrest for the remaining eight years of his life. In 1600 Giordano Bruno was burned to death for refusing to recant the view expressed in his philosophical treatise that the Earth was not the center of the universe. Surely Galileo would have been executed, as Bruno was, had he not recanted.

The criminality of creative individuals can be seen as two general types, (1) creative acts or creative products that are seen as criminal, or (2) lifestyles that are seen by society as criminal. Examples of the first type would include Jesus, Martin Luther King, Jr, Gandhi, Galileo, Egon Schiele, O. Henry, and Lenny Bruce; these are individuals who were jailed because their product, theory, or performance was considered criminal by society. The second type consists of individuals who are singled out as criminals because of their lifestyle; this would include Oscar Wilde, Cervantes, O. Henry, and Herman Melville. All were jailed because of activities and behaviors not directly related to their creative production. Oscar Wilde, for example, was jailed in Victorian England for homosexuality and pedophilia, and O. Henry was jailed for unpaid debts.

The main crimes that are perceived as threatening to the existence of the state have been relatively constant over the years. They are: (1) treason (levying war against the government), (2) sedition (stirring up treason or rebellion), and

(3) morality; crimes against public decency (illicit sexual conduct, gambling, unpaid financial debts).

The metaphor of a wedding cake has often been used for the criminal justice process. A wedding cake is narrow at the top and gets progressively wider toward the bottom. The wedding cake model of criminal justice divides cases into different tiers: (1) a few celebrated cases in the top tier, (2) a greater number of 'real crimes' in the second tier, (3) most ordinary felonies in the third tier, and (4) the vast numbers of misdemeanors in the fourth tier. By far, the greatest number of cases fall in this last category.

Creativity, Conformity, and Rebellion

There is a central problem for the creative mind, which is an essential tension between creativity and conformity. Conformity is doing things as others do and have done; on the other hand, creativity is doing things in a novel way as well as breaking out of established patterns. As a result of this break, the creator is frequently seen by society as a rebel, a deviant, and a gadfly. Creativity and deviance are in many ways synonymous. The creator must rebel against, contradict, and negate established ways of thinking. New ideas commonly are met with societal repression. It takes time for culture to accommodate to the unfamiliar. For these reasons, Galileo, Martin Luther King, Jr, Henry David Thoreau, and others have spent time in jail. The creator is often faced with a society that finds his or her production offensive, monstrous, or crazy. The school of painters known as impressionists were considered mad and their art decadent by many critics when it was first promulgated in the mid-1800s. The American poet Walt Whitman was considered an oddball and madman by many critics when his *Leaves of Grass* was first published.

Henry David Thoreau, Martin Luther King, Jr, Thomas More, Socrates, Galileo, Jesus Christ, and Joan of Arc are all historical figures whose names evoke awe and strong emotions. They have been immortalized in books, movies, and television programs, and some (Jesus Christ, Martin Luther King, Jr) have official holidays in the United States dedicated to them. One thing they have in common is they were all placed in jail by their cultures for their unorthodox, nonconformist views. Some of these individuals – Socrates, Joan of Arc, Thomas More, and Jesus Christ – were put to death by society. The views of these people were seen by conventional standards to be so dangerous that elimination of the individual was the only way to keep the rebellious thoughts from spreading. There are many other cases of individuals being persecuted for their nonconventional views. Victor Hugo, perhaps France's greatest writer and creator of *Les Miserables* and *The Hunchback of Notre Dame*, was forced to leave his homeland and go into self-exile to avoid being arrested by the French government because of his written attacks on that institution. Emile Zola, in response to writing *J'Accuse*, fled his homeland.

Exemplary Cases

Leni Riefenstahl was born on 22 August 1902. She is considered by some to be a war criminal and by others a film genius. Early on, she was a ballet dancer, painter, and actress; she was athletic and attractive. In 1932 she directed her first film and drew the attention of Adolf Hitler. Following his accession to power, he chose her to film a Nazi party rally. Riefenstahl used 36 cameramen and assistants to chronicle the rally in perhaps the most notorious documentary ever filmed, *Triumph of the Will* (1935). The film is a masterwork of montage, editing, camera angle, and *chiaroscuro*. After the Second World War she was imprisoned by the French for taking an active part in the Nazi propaganda machine and spent almost 4 years in various prisons and detention camps. She always contended she was merely a film-maker and had no intentions to support the Nazis. She later tried in vain to resurrect her career, failing several times to actualize filming projects in Africa and elsewhere, and worked instead as a still photographer for European magazines.

The French painter Gustave Courbet (1819–1877) was jailed due to his involvement as both an artist and an art administrator. Courbet served as chairman of the Art Commission under the short-lived commune; he was accused of having dismantled the Colonne Ven-dome and was imprisoned at Sainte-Pelagie, where he painted some fine still lifes. *The Stone-breakers* (1850) and *Burial at Ornans* (1851) were criticized as being 'distasteful.'

Edward Dmytryk (1908–present), a Canadian-born film director, made several socially oriented films in Hollywood in the 1940s. His fellow director Sam Wood appeared before the House Committee on Un-American Activities in the 1950s, during the great 'red scare' and blacklisting of perceived communists at the time, and gave Dmytryk's name as a possible communist sympathizer. Refusing to appear before the committee, Dmytryk was fired by RKO film studios and went to England to make movies there, unfettered by the severe limitations imposed in Hollywood by both the government and the

studio executives. Forced to return to the United States to renew his passport, he was arrested and jailed for six months. Later, he recanted and himself named names before the committee, and subsequently resumed making films in Hollywood.

In 1922 Gandhi (1869–1948) was given a six-year jail sentence, of which he served two years, for his nonviolent practice of mass civil disobedience. He was jailed for launching a civil disobedience movement that was pivotal in undermining the British political hold in India. His calling came to him late. In early adulthood, he went through a crisis in which he was a lawyer at his father's urgings. His efforts at law were disastrous; during one case before the bar, he reports in his autobiography that he got so tongue-tied that when he went to speak, nothing came out but a few incoherent stammerings. Gandhi's doctrine of 'passive resistance' was based on an idea he got from the American writer Henry David Thoreau.

Gandhi reports in his autobiography he had a succession of early experiences that shaped his vision of passive resistance. It was not, though, simply a matter of experiencing certain events, but rather Gandhi mentally operated on his experiences in such a way that it gave form and meaning to his philosophy and his actions. One of the most famous demonstrations of civil disobedience of all time was the Salt March of 1930, in which Gandhi demanded the abolition of the state tax on the sale of salt. The salt tax, he felt, was especially unethical and immoral since it had its greatest impact on the poorest of the Indian people. In pursuit of its abolishment, Gandhi organized a 165-mile walk to the sea so that people could procure their own salt. This demonstration brought a lot of empathetic international attention to Gandhi's cause and proved an enormous embarrassment to the British government. Subsequently, Gandhi and some of his followers, including Nehru, were jailed.

Emma Goldman (1869–1940) was an American anarchist; editor, and lecturer who devoted her adult life to social causes. She was born to Jewish parents in Kovno, Lithuania, and early demonstrated a rebellious spirit. At 16 years of age, she went to America with her sister, and they settled at Rochester, New York. In 1889 she moved to New York City to join anarchist causes. In 1893 she was jailed for nine months on a charge of inciting to riot after telling a crowd of unemployed workers to steal food and other things if they were in need. In 1906 she founded *Mother Earth*, an anarchist publication which she edited until its suppression in 1917. She was jailed again in New York in 1916 after giving a public speech favoring birth control. When the First World War began, Goldman opposed entry into the war, and was again jailed and sentenced to two years. When she completed her jail sentence, she was stripped of her US citizenship and deported to Russia. In Russia, she continued her anarchistic expressions and fled that country, fearful of social oppression and imprisonment. In 1931 she published her autobiography, *Living My Life*. While living and working in Toronto, she died from a stroke at age 70.

In Tahiti, in 1891, the artist Paul Gauguin (1848–1903) was jailed for writing a letter criticizing the local government officials. He was seen as a gadfly by the officials. Gauguin liked women. He set out to find one in Tahiti. At a neighboring village he was offered the hand of a young native named Tehura who was barely in her teens. Gauguin was immediately

attracted to her and she to him, and it was decided there would be a week's trial marriage to ensure that the partners were free of disease and willing to freely extend the relationship. After a week, she agreed to remain permanently, and, with Tehura by his side serving as a model, the artist was inspired to work hard and executed many works of his nude wife, including the famous, *The Spirit of the Dead Is Watching*.

Galileo Galilei (1564–1642) was considered a criminal for extending Nicolaus Copernicus's idea that the Earth was not the center of the universe. Nicolaus Copernicus (1473–1543), the noted Polish astronomer, outlines his theory that the Earth revolves around the Sun in his great work, *De Revolutionibus*, which was published in the last year of his life. For this reason, it is quite likely that he avoided societal repression, which is not the case for Galileo. Galileo had a history of confrontation as well as being an independent thinker. As a child he was an annoyance to his teachers; he questioned and contradicted at every turn. His father wanted him to be a physician but the youthful Galileo chose science. As a scientist, he entered Pisa University as a student in 1581. At 19 years of age he observed a swinging lamp in the cathedral at Pisa which led him to investigate the properties of a swinging pendulum. When only 25, he taught math at the University of Pisa. After three years he was forced to resign, in trouble due to his original ideas and forceful expressions. In 1592 he became professor of mathematics at Padua, where he made a telescope and his observations led to a number of discoveries that marked a scientific revolution in astronomy. Galileo discovered the satellites of Jupiter, supporting the planetary theory of Copernicus. In 1592, he moved to Florence as mathematician to the Duke of Tuscany. He observed sun spots and the existence of Saturn. From 1613 to 1615 he was confronted by the Holy Office of the Church and warned not to teach his neo-Copernican doctrine. In 1632, Galileo promulgated his great work, *The Dialogue of Two Systems of the World*, and the controversy of planetary motion was reopened. Summoned to Rome by the Church, he recanted and was placed under house arrest in Florence. He spent his remaining years there, becoming blind in 1637 and dying in 1642.

Aphra Behn (1640?–1689) has often been referred to as the first professional English woman writer to earn a living from her writing. Before she became a writer, Behn was employed in 1666 as a secret agent for the English government. As part of her assignment, she went to Antwerp to gain information about exiled Cromwellians and to relay Dutch military plans. During her activities as a secret agent, she used the name 'Astrea' as her alias; she would later use the name 'Astrea' as her literary name. She ran into enormous debts incurred during her royal service, and in 1667, when she returned to England, she was detained in a debtors' prison. Behn suffered enormously. She pleaded to the King to pay the debt. She wrote to a friend:

I have cried myself dead and could find in my heart to break through all and get to the king and never rise till he were pleased to pay this, but I am sick and weak and unfit for that or a prison. (Todd, 1992).

A generous friend, who remains unknown, eventually paid her debt and she was free to pursue her writing career. Behn entered the theatre as a playwright in 1670. She became a

literary celebrity, achieving success and fame as a playwright. Her prefaces to her plays openly defended her right as a woman to earn a living through the efforts of her pen. Two of her most frequently anthologized plays are *The Rover* (1677) and *The Lucky Chance* (1686). In 1687 she found herself in trouble with the King yet again. She offended King Charles II by attacking in an epilogue to her play, the King's illegitimate son, the Duke of Monmouth. She was arrested and briefly imprisoned for this offense. In the last years of her life she turned to fiction writing, and wrote more than a dozen novels, including *Oroonoko* and *Love Letters Between a Nobleman and His Sister*. The latter novel was based on the true scandalous story of the elopement of Lord Grey of Werk with his wife's sister, Lady Henrietta Berkeley. The novel was a best-seller. Behn had long been praised in literary circles as 'sole Empress of Land of Wit' (Todd, 1992). Her fame earned her a burial in the prestigious Westminster Abbey.

Daniel Defoe (1660–1731) turned to writing after his various business ventures failed. In 1702, he wrote a pamphlet, *The Shortest Way with the Dissenters*. Himself a Dissenter, Defoe, in the pamphlet, took a satirical stance by demanding the suppression of Dissenters. The pamphlet was judged to be critical of the Anglican Church of England. Defoe was ordered to pay a heavy fine, was ordered to stand in the Charring Cross Pillory, and sentenced indefinitely to Newgate Prison. He was released from prison with the help of Robert Harley, Tory Minister, for whom Defoe undertook intelligence and propaganda work. But Defoe's legal troubles did not end. In 1713 he was arrested for debt twice. He worked to recover his fortunes by serving as a political spy and propagandist for the successive Whig ministries, and by writing fiction. Defoe's most famous work of fiction, *Robinson Crusoe* was published in 1719. The novel was an immediate success, and became one of the top three best-selling novels of the eighteenth century. Defoe went on to write several more successful works of fiction, including *Moll Flanders* (1722), and *Roxana* (1724). Despite his financial gains from fiction writing, Defoe died in debt, hiding from his creditors.

The Zeitgeist and the Individual

Creativity by its very nature involves nonconformity and a departure from old, traditional ideas. There are mechanisms of society – roles, paradigms, habits, accepted ways of doing things – that resist change. However, a Zeitgeist – the entire philosophical and spiritual temperament of a culture – can vary as to the receptivity to new ideas. Einstein, for example, overturned Newtonian physics and was a hero; Galileo, on the other hand, overturned the then-conventional view that the Earth was the center of the universe and was condemned, detained, and forced to recant.

Certainly, many creators were immediately recognized by their contemporaries, such as William Shakespeare, Charles Dickens, Albert Einstein, and Walt Disney. On the other hand, some creators encountered enormous resistance to their ideas, such as Courbet, Egon Schiele, Walt Whitman, Charles Darwin, and Ignaz Semmelweis. In the case of Semmelweis, it might be said that today's rebellion can become tomorrow's conformity. In 1847, Ignaz Semmelweis (1818–1865), a Hungarian

physician, got the idea that patients were contracting puerperal fever due to the pre-examination procedure of the doctors. The disease, he reasoned, was being carried to the patients on the hands of the medical staff, and he devised a procedure in which the hospital personnel washed their hands immediately before the examination with a solution of chlorinated lime. Unfortunately, his ideas were not well received. He embarked on a crusade to have his procedure accepted, and in a great part due to the public ridicule and resistance that his idea received he had a mental breakdown and was assigned to an asylum in 1865. Some time later, Pasteur followed up with Semmelweis's discovery, and, partly because people were more willing to accept the idea and partly because Pasteur was a better salesperson than Semmelweis, the notion of washing hands in chlorinated lime before medical examinations found wide acceptance.

How the perceptions of *Zeitgeists* vary regarding deviance can be seen by comparing Lewis Carroll (1832–1898) and Egon Schiele (1890–1918). Both men used nude, under-aged girls as models; Carroll photographed them and Schiele painted them. However, Schiele was jailed for lewdness and Carroll was not. Carroll's *Zeitgeist* was nineteenth century and pre-Freudian; people did not see sexual implications in his conduct. Schiele's *Zeitgeist*, on the other hand, was twentieth century and post-Freudian; there was a heightened sensitivity to the sexualization of children and a changed attitude about a child as a sexual cathexis for an adult. Whether a given act is perceived as deviant, and leads to societal repression, depends in part on the nature of the act within the societal framework or *Zeitgeist*, and in part on what society does about it. There is another issue to consider. Even when an individual is persecuted by society, often there is a fence that divides supporters from detractors. Freud and Darwin, for example, were condemned by the religious community but staunchly supported by some members of the scientific community to which they belonged. A further dichotomy can be made. For some individuals, part of their total work might be accepted while another part is rejected; the sculptor Epstein provides an example of this type of division.

One of the most repressive *Zeitgeists* to be found historically is the society headed by the Nazis in Germany in the 1930s and 1940s. Many works of art, including paintings and musical compositions, were banned. The Nazi government sponsored art shows that displayed 'decadent' art (the artist/teacher Paul Klee was included). Many famous people, including Albert Einstein, Sigmund Freud, and the composer Richard Strauss, fled Germany to avoid persecution. In fact, German scientists who fled Germany played a pivotal role in developing military technology that helped win the Second World War for the United States and its allies.

Crime, Creativity, and Paradigms

Thomas Kuhn introduced the idea of a paradigm shift. Paradigms are patterned knowledge bases that are culturally shared to explain and give meaning to phenomena. Kuhn suggested that societies have paradigms to explain experiences. A paradigm will exist, according to Kuhn, until a better one comes along. In pre-Copernican days, for example, people believed

that the Earth was the center of the universe. Copernicus and Galileo suggested a different paradigm in which the Earth circled the Sun. The new paradigm was not warmly received by everyone, since it contradicted cherished beliefs. Extending Kuhn's idea of paradigm, we introduce a distinction between 'hard' paradigms and 'loose' paradigms. A hard paradigm is one in which cherished beliefs are protected and maintained for a number of reasons, including emotional, philosophical, and personal. On the other hand, a 'loose' paradigm has gaps, questions, and omissions for which people beg for answers; it welcomes a new perspective. Galileo stepped into and confronted a 'hard' paradigm; people who supported the prevailing *Zeitgeist* that existed prior to Galileo's theory were not interested nor motivated to seek or explore new explanations. Galileo was imprisoned. Einstein introduced his theory of relativity to a *Zeitgeist* that welcomed a fresh, novel, organized theory that explained the currently unexplainable. Einstein was a hero in the United States. He is a cultural icon. His face can be seen on t-shirts as well as innumerable posters.

The Psychology of Rebellion
