would reside in specialized processing units separable from language and, more generally, general intellect. Moreover, this position leads to the position that different facets of creative activity are each served by their own modules, with their own set of mental operations. Along these lines, the linguist Ray Jackendoff has suggested separate modules exist for music, language, and dance-related activities. There is some evidence as well that different domains of creative activity are mediated by different brain structures, a position consistent but not necessary for modularity. As extended further, a strict modular approach would be in line with multifactorial approaches to understanding creativity, such as the structure model proposed by Guilford, and inconsistent with theoretical models that posit a more general approach to creativity, such as through a generalized associate network (and implemented in such tests as the Remote Associate Test).

Psycholinguistics After (or in Opposition to) Chomsky

The post-Chomskyan era has seen notable changes to many of the questions about language and creativity, from both linguists and psychologists. Moreover, especially in the last two decades, moment-to-moment (on-line) measures of language processing, and the use of large-scale language corpora have become importance tools, displacing for many, the artificial, single sentences employed as test stimuli and the dependence on the intuitions of native speakers characteristic of the Chomskyan era. Theoretical approaches now are more integrated with ideas arising in cognitive science and in neuroscience.

Linguistic Approaches

Three of the many developments in linguistics deserve special mention. On the one hand, there were reactions to aspects of the 'standard theory' and alternatives have appeared in the literature challenging either one or another of the assumptions posited by Chomsky and the mechanisms he posited as necessary. Nonetheless, in one way or another, these alternatives share some similarity to questions posed, or assumptions taken, by Chomsky found in various forms of Generative Semantics, Extended Standard Theory, Trace Theory, Case Grammar, X-bar theory, among others.

A second and ever-growing development is described under the general rubric of 'cognitive linguistics.' This approach developed because of the sense that Chomskyan theories (and their derivatives) could not account for many instances of everyday language. Most radically, cognitive linguists hold that linguistic structures are motivated by, and otherwise related to, human conceptual knowledge and the communicative functions of discourse. In direct opposition to a modular view, language is assumed to be motivated by cognitive structures which in turn can be traced to the ways we perceive, physically manipulate objects and interact with our environment. From this perspective, speaker's use of language activates knowledge in one's conceptual system; the linguistic input alone, however, is not sufficient to explain the emergent meaning that arises. One can also analyze the language one produces to get insights into the underlying conceptual systems. Simply

put: if language is creative it is because of basic cognitive processes and not because of linguistic properties alone. This general approach can be traced to various theorists working from the 1970s onward, including George Lakoff, Ronald Langacker, Adele Goldberg, Paul Kay, and others. With respect to the study of creativity, two developments within this school of thought are most influential, namely conceptual metaphor and conceptual blending.

Conceptual blending is most associated with the writings of Mark Turner and Gilles Fauconnier. In general these theorists have expanded on Arthur Koestler's notion that 'bisociation of matrices' is the basis for human creativity. Blending theory has attempted to more formally describe the way concepts are structured (in mental spaces) and the various optimality principles that guide its usage. In essence, blending theory is an attempt to describe how information from two or more spaces is combined to produce a novel cognitive structure. Their basic model consists of four connected spaces, namely two separable 'input spaces' that can be blended, a 'generic space' of stock conventions and image-schemas that allow the input spaces to be understood from an integrated perspective and, finally, a 'blended space,' which consists of a representation in which selected projection of elements from both input spaces are combined and inferences arising from the combination. A set of principles describe how a well integrated novel structure arises: for instance, the 'access principle' holds that a value in one input space can be described by the role that its counterpart plays in the second space, even if that role is invalid for the first space. Thus 'blends' provide a cognitive representation and creative synthesis that permits for the manipulation of separable events as an integrated whole. Blending theory has been applied to a wide range of creative products, including metaphor, humor, and neologisms. In recent years there has been some success to implementing blending theory in a computationally-realized model by Francisco Pereira, and supportive psychological evidence has been found by Seana Coulson using fine-grained temporal measures of comprehension. Despite these successes, the theory is mute on creative motivation; the theory has yet to describe how a given individual chooses the input spaces to be blended to produce a desired, creative, effect.

Conceptual metaphor can be traced to a seminal book by George Lakoff and Mark Johnson, *Metaphors We Live By* and has since been expanded by Mark Turner, Zoltan Kövecses, and others. The fundamental tenet of the theory is that metaphor operates at the level of thinking, not language per se. Metaphors link two conceptual domains, the 'source' domain (typically consisting of literal and concrete entities and relationships) and the 'target' domain (often a concept more abstract or less amenable to a simple description, such as 'LOVE' or 'ANGER'). The target domain takes its structure and is understood in terms of the source domain. Thus how we conceptually structure, and talk about the target domain parallels the structures and knowledge held about the better-delineated source domain. Target domains are therefore believed to have relations between entities, attributes, and process that mirror those found in the source domain. At the level of language, one can thus find words and expressions (so-called metaphoric expressions) about the target domain that refer directly or implicitly to the source domain. Indeed the main source of evidence for the reality of conceptual

metaphors is based on patterns of word or expression use. Thus for instance, a proponent or conceptual metaphor theory might notice a set of sentences that are, from a traditional perspective, semantically distinct but can be shown to share a metaphoric relation, such as sentences that all are based on the notion that LIFE IS A JOURNEY or that the MIND IS A BRITTLE OBJECT or LOVE IS A DISEASE. Despite the widespread popularity of this theory, evidence for the psychological reality of conceptual metaphors is largely based on examination of patterns of language use, largely has been uncritically accepted, and has not been supported often when tested in ways other than through the intuitive linking of patterns of language use. The weakest evidence to date is for the proposition that conceptual metaphors are automatically engaged when one processes language.

The import for creativity is twofold. First, conceptual metaphor theory explicitly denies that literal and figurative language, even expert-level creativity found in creative literature, differ in important ways; literal language too is motivated and structured by conceptual metaphors. Given the importance of metaphor, neologisms, irony, humor in creative writing, and other forms of creative discourse, conceptual metaphor theory makes the strong argument that the cognitive underpinnings of creative output, such as with poetry or avant-garde literature, does not differ from noncreative output, such as found in everyday speech. Second, metaphor and analogy have long been discussed as the basis for scientific and artistic creativity alike. In principle then one can envision that conceptual metaphor theory can serve as a basis for understanding both everyday and novel creative output. However, to date, conceptual metaphor theory is underdetermined with respect to how novel metaphor mappings occur. For instance, it has been shown that the historical introduction of a novel mapping (such as describing personality to perceptual qualities, such as 'she is rough around the edges' or 'he is a smooth talker') is within a short period of time followed by an explosion of new expressions based on that mapping. Presumably some mechanism is required for that initial insight which, retroactively, might be describable as instances of conceptual metaphor. In principle, the many determined attempts to implement computational models of analogy and metaphor, some based on conceptual metaphors, might provide some insights into the initial novel mapping, as might applied creativity programs based on the use of metaphor and analogy, such as Synectics.

A third linguistics development can be found in what has been labeled 'corpus linguistics,' the study of language based on samples (or corpora) of 'real world' text or speech. Typically these corpora are very large, encompass a wide range of types of texts or social situations, are computerized and can thus be used to examine any number of questions, such as the frequency with which different types of speech (e.g., irony or metaphor) are actually used in everyday communication. This development can be seen, in part, as a reaction to another distinction made by Chomsky, namely the distinction between linguistic competence and linguistic performance. The former refers to the knowledge held by an ideal set of speaker-hearers and was the database to Chomsky and many of those who followed in his linguistic footsteps. According to Chomsky one can tap for this knowledge by asking adult native speakers about their intuitions regarding presented sentences.

In contrast, linguistic performance refers to the actual use of language in specific situations, and, from Chomsky's perspective such language is error riddled with extraneous factors and not the proper source with which to understand human linguistic competence. Performance-related 'errors' would, from a Chomskyan perspective, include limitations and distortions such as those produced by fatigue, working memory capacity, stress, and the like. The contrary argument is that corpora provide a basis for language as actually used and thus permit for the study of language in an ecologically valid manner and for consideration of sociological and pragmatic factors in language production and comprehension. For instance, CANCODE (the Cambridge and Nottingham Corpus of Discourse in English) is a collection of spontaneous spoken English comprised of about five million words obtained in a wide variety of situations, including casual conversation, people working together, people shopping, people finding out information, and in discussions. Examination of corpora, especially by Ronald Carter and his colleagues, has shown that original, creative speech is frequently found in everyday speech (and is not the unique province of poets or professional writers) and, when used, is a marker often of social standing and interpersonal relationships. It is expected that the use of corpora will become even more important in coming years.

Experimental Psycholinguistics

By experimental psycholinguistics we are referring to studies in which laboratory based experiments are performed, using linguistic stimuli under well-controlled conditions in which select variables are independently manipulated. The emphasis in recent years has been on the use of online measures derived from techniques that permit the tracking of mental processes during the act of comprehension or production. One such technique that has proven useful are Event Related Potentials (ERPs), the tracking of electrical brain activity tied to the onset of some stimulus, such as a presented word or a word embedded in some longer context. An ERP component of especial importance is a negatively going electric wave with a maxima about 400 ms after stimulus onset (the N400); the amplitude of this component is a measure of the violations of expectation, and hence of the difficulty of integrating the new information into the discourse structure being constructed online.

Comprehension Experiments

In the 1960s, psychologists attempted to take one or another linguistic theory as the basis for their experiments, testing whether the tenets of the theory were psychologically real. For instance, considerable research examined whether a sentence would be more difficult to process the further its s-structure was from its d-structure, whether people psychologically parsed sentences as predicted by a phrase structure grammar, and whether observations of children's acquisition of language provided evidence for an innate schema or universal grammar. The evidence in support of Chomsky has been questionable and in more recent years psycholinguists have abandoned a strict dependence on formal psycholinguistic models of the type championed by Chomsky to study language production and comprehension, largely using online

methodology and explaining their findings within memory-based or other mainline thinking in the cognitive sciences.

One active area of research has been on testing syntactic modularity, which is the notion that the initial syntactic analysis of a sentence proceeds independent of semantic, contextual, and pragmatic knowledge. One early influential theory by Lynne Frazier adopts a modular perspective in which people adopt two strategies in comprehending syntax: late closure (the tendency to attach each word to the clause or phrase being processed) and, minimal attachment (the tendency to add that word to build the simplest possible syntactic structure). Tests of this theory have tended to employed so-called garden path sentences such as 'The lady sent the flowers was very pleased' and have employed online measures, such as the monitoring of eye movements while reading such sentences. The assumption is that one can get insights on how a sentence is parsed, assuming word by word processing. In the sample sentence above, minimal attachment would place the words 'sent the flowers' as the verb phrase which would attach to the noun phrase 'The lady.' According to the theory, on encountering the next word, 'was,' the parser would recognize that the initial assigned syntax is incorrect, causing a delay in the processing of that word (seen in longer than expected time spent looking at that word and regressive eye movements back to the earlier words, assumed to indicate a reassignment of syntactic constraints). Within this paradigm, modularity has been tested by placing the critical sentences in extended context that bias toward one or another reading, or by using sentences in which pragmatic factors are important. On balance, these studies indicate that even the most basic syntactic resolution involves the continuous consideration of syntactic, semantic, and pragmatic factors. Some of the models that have emerged from this line of research have been implemented in psychologically real computational algorithms, often adopting a processing approach (such as 'constraint satisfaction') that is similar in kind to mechanisms proposed for other mental processes. In a more general way, processing of language is considered in relation to the structure and operations upon knowledge held in permanent memory stores and, as such, are aligned more with cognitive psychology than with linguistic theory.

Another very active area of research over the past decade has been into the processing of nonliteral language (in which what we say differs from what we intend to convey), including metaphor, irony, idioms, proverbs and the like, all instances of creative language use, and in some cases artistic endeavors. These ubiquitous forms of language were marginalized in Chomskyan theory. Many of the same issues discussed above are found here as well, namely arguments surrounding whether there are obligatory processes that one must initiate before a nonliteral meaning can be assigned or whether one can directly adduce the figurative sense. Proponents of the former stance include those who argue that one must process the literal sense or, in a more recent variant by the linguist Rachel Giora, the salient (most frequent usage) sense. In contrast others, including most notably the psychologists Sam Glucksberg and Ray Gibbs, have argued for their own versions of direct access. These latter approaches have tied metaphor and some other forms of figurative language to mainline cognitive psychology, such as that studied in the semantic memory, event

structure, categorization or the embodied cognition literatures. The latter approach is complementary also to the cognitive linguistics approach described above, and by a psychological linguistic theory, Relevance Theory, in de-emphasizing a standard distinction between literal and nonliteral language traditionally held as important for explaining processing differences between figurative and nonfigurative language.

Production

It is generally held that the production of speech (or in writing) consists of a set of steps, from having a thought, translating the concept in a way that makes it available for output, accessing the appropriate units (such as words or morphemes), arranging these units into the appropriate sequence (syntax), and engaging the appropriate motor or output units. There is now an extensive literature on each of these topics, most of which describe everyday language production issues in general and not those related to more exceptional or artistic creative production. As with the work on comprehension, a salient question that remains to be answered is whether language production is modular, and especially whether language production and comprehension are mediated by the same set of processes. In very recent years there has been some work at understanding literary production, both by people working in the cognitive linguistic tradition and by some experimental psycholinguists. For instance, poetic (haiku) language production has been studied both offline and online by Dawn Blasko and her colleagues.

Conceptual Combinations

A task that has gathered considerable interest in recent years is that of 'conceptual combination,' a task that simplifies the examination of linguistic creativity. The task consists of presenting two words, such as the noun-noun pair 'pet shark' (in which the first term is considered the modifier term and the second as the head noun) and asking for an interpretation. Of interest is the speed with which an interpretation is typically given and the diversity (creativity) of the interpretations offered. Theoretical explanations for performance in this task mirror those found in the more general post-Chomskyan psycholinguistic literature when examining sentence and discourse processes. There are theories rooted in the semantic memory literature such as those that posit a schema-based explanation in which the head noun consists of a set of slots that can be filled by specific attributes, which in turn is facilitated by semantic and pragmatic factors. There are theories based on the event structure literature such as those that argue task solution is based on finding an appropriate thematic relation that links the head and modifier nouns; thematic relations would include location, causal, temporal and similar event-based factors, with preferred solutions based on a pragmatic factor – the frequency with which a modifier has been used in different relations. Finally, there are constraint-based explanations such as those that argue interpretation is based on three 'constraints' found in the pragmatics of communication: diagnosticity, plausibility, and informativeness. Creativity arises because these constraints can be satisfied in many ways. Constraint-based theories have their origin in explaining

perceptual processes but have been extended to higher level processes in more recent years, resolution of syntactic problems and, even to the resolution of proverbs by Albert Katz and Todd Ferretti and to irony by Penny Pexman. Strength of the constraint-satisfaction approach to the processing of conceptual combinations is that it allows for interpretations emphasized by both the schema-based and the event structure based models. Recently, Fintan Costello and Mark Keane have produced a computational algorithm to instantiate the theory; simulations of this algorithm produce responses similar to those produced by people.

Language as a Social Phenomenon

Creativity has been viewed predominately from the perspective of the individual creator and not as a social phenomenon in which creativity involves the interactions of people working together. This perspective predominates in the psycholinguistic literature also. An exception can be found in the study of eminent creators by Dean Keith Simonton who, employing statistical analyses, examines eminence in a range of creative fields, has examined the role of cultural and situational factors in perceived creative expertise. Recent work, examining the communicative aspects of everyday language is also challenging this traditional view, finding linguistic creativity often to be a product that emerges from interactive cocreation between interlocutors.

Several instances of this emerging literature are reviewed here.

Repetition and Recontextualizing

One observation in sociolinguistics has been that elements of a speaker's language in conversation (such as accent or use of specific words) are often repeated back by others in response. Two approaches to this phenomenon predominate in everyday interactive language creativity. According to Communication Accomodation Theory, the pattern wherein a person mimics or repeats the speech pattern of an interlocutor (or diverges from a common usage) can reflect displays of identity and social cohesion. Thus, for example, a person's ethnic accent may become even more pronounced when talking to a person openly hostile to his/her ethnic group. The emphasis here is social communicative factors. In contrast, a cognitive theory, the Interactive Alignment Model, places repetition as a priming mechanism in which the type of language used by one person automatically primes the corresponding representation in an interlocutor. Thus if one person uses passive sentences frequently, an interlocutor will tend to adopt this form of speech in response. Once activated, other levels of representation can be aroused in a spreading activation manner. Thus, the use of passives by one person can activate a corresponding structural representation in the interlocutor which, in turn, could spread to related semantic representations. These effects from one person to another proceed automatically and hence are not under motivational control. This theory best explains aspects of convergence and is less successful in explaining divergence, such as described above.

Both theories do posit that the creative or novel use of language by one person is triggered by the person with whom one is

talking. Very recent work has shown that use of metaphor by one person is met by repetition by an interlocutor, in the sense that the interlocutor adopts metaphor in his or her responses. Some have speculated that repetition in language is related to musical creativity, such as found with the call-response in African music and the later usage in jazz, and, as well, with sampling, a music style in which the artist creates a new piece of music from fragments of music already available in the canon.

Creative Language as Playful Pretense

As a developmental construct, play is viewed as learning through mimicry, that is, based on everyday observation of the behaviors of others. Children's language in pretend play has been taken as indicating the child has mastered the symbolic and creative use of words. For instance, a child may label a bowl of mud as 'soup' but never attempt to consume the mud. A related interactive observation has been labeled 'comical hypothetical discourse,' namely playful creative linguistic behavior which depends on the conjoint production by interlocutors in its creation. This cocreative conversational phenomenon typically begins with a reference to an imaginary circumstance. Unlike storytelling, the comical hypothetical invites interlocutors, often indirectly, to participate in the creation of a hypothetical event or situation. For instance, when a conversation has been about the loss of a winning lottery ticket, an interlocutor might ask a friend to imagine what he or she could do if they found the ticket. After initiation, the exchange must be acknowledged by creative additions and an imaginary scenario built by more than just the initiating speaker to become a comical hypothetical exchange. The exchange itself represents a form of playful pretense; such creative language play is seen as maintaining and reinforcing social bonds.

Play Theory and Gender

Recent work has examined the use of metaphor in conversation. One finding of interest is that males are more likely to use metaphorical and other forms of figurative language, and to use it at an earlier age than females. This effect is most marked in same-sex conversations and when the males are strangers to one another. Friends of either gender produce roughly equivalent amounts of metaphor in conversation. On the face, this observation not only is consistent with comical hypothetical discourse but, given its prevalence when communicating with strangers (and not friends) is consistent also with the hypothesis that creative and humorous language use in male-male conversations are instances of male dominance display and consequently as an expression of socially acceptable male competitive behavior.

Online Communications and Creativity

In contrast to the face-to-face examples described above, in which communication can depend on prosody, gesture, dress, and other cues in addition to the language employed, online cues minimize many of these factors, though the need for extra-linguistic or pragmatic factors in creative communication is still apparent by the development of emoticons and the

use of newly created neologisms to mark intent, such as 'lol' (for 'laugh out loud'). A novel enterprise has been to look at the nature of the communications themselves, shorn of obvious cues to social factors such as gender or race. For instance, both gender and personality may be marked in online communications. Examination of e-mails have shown that men and women tend to describe their holidays in different ways, with men emphasizing impersonal topics (such as description of location and the journey) whereas females tend to write about social and domestic topics and, contain a higher incidence of features associated with the maintenance of rapport and intimacy. With respect to personality, higher levels of extraversion have been shown to be associated with a tendency to use adjectives in e-mails, whereas lower levels of neuroticism are associated with a preference for the use of adverbs. Finally, there are studies that have looked at group creativity in a 'virtual' setting. There is a long history of examining group creativity in science research labs, technological and business units. A recent manifestation is 'virtual' groups brought together to solve problems, each member working with the unit at a distance, linked by computer. To date, the emphasis has been on understanding how people in this context can create a common ground and visual workspace in which to interact. It is expected that the efficacy of such groups in producing creative output will be examined in coming years.

Summary

In general, the data and theorizing arising from the psycholinguistic literature emphasizes: (a) similarities between everyday linguistic creativity and creators with the creativity exhibited in domain specific fields and eminent creators; (b) muting the distinction between everyday 'literal' language and the language found in creative literature and scientific expression; and (c) the role played by social interaction in creative output.

Rank's Originality

Otto Rank was a highly original psychologist whose ideas continue to influence creativity researchers, psychotherapists, organizational theorists, and students of the arts and humanities (Figure 1). Many of his important concepts have entered the mainstream of psychological thought. He was Sigmund Freud's closest associate for 20 years, a major contributor to the literature of psychoanalysis, editor of two journals in the field, and a prolific writer and lecturer in France and the United States. He wrote about philosophy, art and literature, anthropology, spirituality, and education, and he developed an approach to psychotherapy based on existential and humanistic beliefs. Rank is known especially for his description of the 'artist-type,' the strong, self-created type of person Rank himself became.

Rank was a comprehensive thinker and researcher who, throughout his life, was drawn to aspects of human experiences that occur across cultures, and was fascinated with the recurrent themes of literature and myth: the mystery of creation, the heroic overcoming of tragedy, and the importance of living life artfully. From a young age he thought of his own life as a challenge to be met creatively through honest self-reflection, conscious and intentional action, and what he called 'self-appointment,' that is, creation of one's own personality.

Born in 1884 in Vienna, Otto Rank grew up in a working-class Jewish neighborhood. He was the second child of an alcoholic and abusive father. His older brother was permitted to pursue a career in law, but at age 14, after middle school, the young Rank was steered toward more practical, technical training that would equip him to work in a machine shop. Resolving as an adolescent to escape from his father's rages, Rank engaged in a process of self-reflection, reading, and self-education, and began recording his thoughts in a diary. At 19, as a gesture of rebellion against his father and renunciation of his Jewish religious heritage, he adopted the name 'Rank' to replace his given surname, Rosenfeld.

Hungry for intellectual and aesthetic stimulation, Rank immersed himself in the rich cultural environment of turn-of-the-century Vienna. The city was abuzz with new art, music, and theatre, and the latest thinking in philosophy and science. Rank frequented the library, where he read Charles Darwin's *Origin of Species* as well as the writings of Friedrich Nietzsche, Arthur Schopenhauer, and other philosophers. He attended the theatre, where he saw Henrik Ibsen's plays, and the opera, where Richard Wagner's work was being performed.

He was also fascinated with the newest thinking in psychology by another resident of Vienna, Sigmund Freud, whose book, *The Interpretation of Dreams*, had created a cultural stir. Freud's book, and his thought in general, offered a new perspective on our psychic lives. Into the intellectual conversation of the time, Freud introduced the idea that many of the motives for our behavior are unconscious, but that a careful listener could follow the symbolism in a person's free associations back to early childhood feelings that had been ignored or forgotten. Rank was inspired by Freud's thinking but also stimulated in his own thinking. After reading Freud, he suggested in his diary that "art is life's dream interpretation." Even at an early stage in his life this precocious young man was contrasting his own ideas with Freud's. Rank noted in his diary that dreams may represent unconscious wishes, but that the 'driving element' in our conscious, waking lives is the 'will,' a notion that was to become central to his later 'Will Therapy.'

At age 20, Rank eagerly incorporated Freudian notions into a manuscript he prepared about creative individuals, *Der Kunstler (The Artist)*. Through Rank's contact with his physician, Alfred Adler, the work was brought to Freud's attention. Freud read it approvingly, made suggestions for revisions, and the work was published. At this point in his life Rank was, as he would later acknowledge, fully 'under the spell' of Freud. The feeling was mutual: Freud was charmed by this bright, young, self-taught thinker. He sensed that Rank's appreciation for the arts and humanities, and his grasp of philosophy, myth, and literature, could help broaden and deepen psychoanalysis. Freud, by the way, welcomed those outside the medical profession into the newly emerging domain of psychoanalysis which he considered relevant to many other fields of endeavor. Freud named Rank secretary of the Wednesday night group that became the Vienna Psychoanalytic Society. He encouraged and financially supported Rank's return to academic high school and his eventual doctoral studies in philosophy and German literature at the University of Vienna. Freud, who was almost 30 years older, was more than just a patron; he became a mentor and surrogate father to Rank, which would make their eventual separation especially difficult and painful.

Freud's project was interdisciplinary. He believed symbolic references to unconscious wishes were everywhere: in dreams, slips of the tongue, and jokes, but also in myths and fairy tales. Rank was already well versed in cultural anthropology and what we would today call ethnopsychology. Like the early

Figure 1 Otto Rank, about 1920.

psychologist Wilhelm Wundt, Rank thought myths provided insight into the inner psychic life. In *The Myth of the Birth of the Hero*, published when he was 25, Rank catalogues many stories across cultures and across time, in which a hero or savior is born under difficult circumstances or abandoned soon after birth. Rank looked for common themes in the stories of their births and applied a Freudian template to these stories, revealing recurrent Oedipal themes, that is, themes of ambivalence and conflict with one's same-sex parent.

Rank's doctoral thesis, the first on a psychoanalytic topic, *The Lohengrin Saga*, published in 1911, delves into the story of an Arthurian knight, the same knight who was the subject of Wagner's opera, *Lohengrin*. *The Incest Theme in Literature and Legend*, a nearly 700 page study that showed Oedipal themes were universal, followed soon after, in 1912. Meanwhile bitter rivalries and conflicts had led to Freud's split with Adler in 1911 and Jung in 1912, and Freud sought to avoid such problems in the future by forming a group of trusted colleagues to further the movement. He invited Rank into his secret 'Committee' of followers and defenders of psychoanalysis. The other members were Karl Abraham, Sandor Ferenczi, Hanns Sachs, Ernest Jones, and Max Eitington. In 1913 Rank and Sachs wrote a monograph on *The Significance of Psychoanalysis for the Mental Sciences*, and in 1914 Rank wrote *The Double*, a study of the theme of an unconscious twin or substitute self, a book that continues to be appreciated by scholars of world literature. Thus, by age 30, Rank had firmly established his reputation as a Freudian thinker and a prolific writer.

The First World War dominated the landscape of Europe over the next several years. Rank served in the Austrian army in Poland as editor of a newspaper. He met and married his wife, Beata Mincer, in 1918. The birth of their child, Helene, in 1919, sparked Rank's interest in early childhood development, especially the pre-Oedipal phase before a child is four or five years old. This would eventually lead Rank to a way of thinking that would challenge his mentor. Freud believed that his patients did not have access to memories of this early time in their lives, and discounted the impact of pre-Oedipal experiences on the adults he analyzed, but Rank was beginning to think otherwise.

Rank worked closely with Freud over the next few years; they established an international journal and Rank was responsible for training psychoanalytic candidates who came to Vienna from around the world. Meanwhile, it was a time of both emotional and physical pain for Freud. The war, and postwar inflation had hurt him financially. In 1920, his beloved daughter Sophie died, and his grandson, Sophie's son, died a year later. In 1923 he underwent the first of what

were to be many surgeries for cancer of the jaw, during the remainder of his life. Rank's loyalty was important to Freud during this difficult period, and when Rank dedicated his new book to his adoptive father it was no surprise.

Separation and Individuation

In 1924 Rank published what was to become an historically important book, *The Trauma of Birth*. In it, Rank described birth as the prototype for anxiety and highlighted the patient's relationship with his or her mother as central to analytic work. Rank felt he was extending psychoanalytic thought into new territory. He didn't fully realize at the time that he was declaring his independence from Freud. Previous Freudian thinking emphasized the transference to the father in therapy (the unconscious way patients re-experience ambivalence toward the analyst who symbolically represents their father). At first *The Trauma of Birth* was welcomed by Freud, who only later criticized what we might today call the first 'neo-Freudian' approach. Rank was hurt by Freud's rejection of his thinking and by the cold response of Freud's associates who began to shun him. Being a rebel and an outsider was a familiar role for Rank, however, and over the next few years, while in his early forties, he essentially gave birth to a 'new,' more fully individuated, self.

At the same time his European colleagues were turning away, Rank found an eager audience of social workers and psychologists in the United States, who were looking for a shorter-term alternative to psychoanalysis. Over the next few years he developed what we today regard as one of the earliest existential-humanistic approaches. While psychoanalysis modeled itself on systematic scientific observation like that carried out in chemical analysis, Rank began to talk about therapy, which had connotations of a healing relationship. Rank wrote about his new approach to psychotherapy in *Truth and Reality and Will Therapy*, published in German between 1929 and 1931, and in English in 1936.

Rank's approach stands out in contrast to Freud's. While Freudian psychoanalysis traditionally takes place with the analyst behind and out of view of the patient, relies on the patient's memories, and encourages the analyst to be a neutral observer (a 'blank screen'), Rank's psychotherapy involves the face-to-face dialogue between therapist and client and emphasizes the actual relationship between the two in the present or 'here and now.' In this view the therapist is a real person to be dealt with, a presence in the room. Rank thought of the present moment in therapy as a microcosm, a world in miniature that provides access to the client's life struggles. Therapy becomes less a linear process of "recollection, repetition, and working through," as in the title of Freud's famous 1914 paper, but is rather a mindful engagement in the dynamic therapy relationship. Rank was prescient: current research on psychotherapy process points to just that relationship as a primary healing factor.

While Freud emphasized the importance of consciousness and insight – the gaining of understanding of factors in one's past that influence one's current feelings, Rank placed emphasis on intention and agency, which he called 'will'; this was one of his most important contributions to psychology. Rank thought will arose in response to early prohibitions. The child's

belligerent response to the parent's 'no,' may be the first manifestation of what Rank called 'counter-will,' a negative form of willing out of which positive willing emerges. As the child grows older and becomes socialized he or she learns to hold back or inhibit many impulses and conform to others' expectations. Later in life, the new adult may discover ways to assert him- or herself, separating in a creative and constructive way from others, and establishing a unique identity in the world. Thus will is an organizing, integrative force that can both inhibit and impel action; the ability to freely choose and act in accord with one's choices is essential to full individuation and self-determination.

In his new approach to psychotherapy, Rank was finding his own course of action, and choosing to go against Freud. What Rank called 'will therapy' or 'constructive therapy' elicits the intention and agency of the client. Consciousness alone, like that awakened in psychoanalysis, is not considered sufficient; action is needed to effect change. Insight is not enough; given the choice between new understandings of the self and new experiences, right here and right now in therapy, Rank would have always opted for the latter.

Life Fear and Death Fear

In emphasizing free will and self-determination, Rank was advocating an existential approach to psychotherapy: he thought Freud's view was too deterministic and fatalistic. For example, Freud believed patients are drawn toward death by a 'compulsion to repeat.' He spoke of a 'death instinct,' that inexorably leads toward entropy, an ultimate winding-down of all things in the universe. In contrast to Freud's notion of a 'death instinct,' a drive that impels us fatalistically toward the end of life, Rank talked about a dual fear: 'death fear,' accompanied by 'life fear.' Rank thought that becoming an individual requires separation, the willing choice to live as an independent person, which is the source of life fear. Death confronts us with the prospect of loss of individuality thorough dissolution into the whole, and thus elicits in us the fear of death. Rank recognized that living life fully, that is consciously and intentionally, brings with it an awareness that all things must end, that death is the ultimate limitation on freedom and choice. Both fears can easily lead to anxiety and inaction. Faced with the fear of life we inhibit ourselves and then feel guilt over the unlive life. Faced with the fear of death, we become like a deer in the headlights, frozen in our tracks, and unable to make the choices and take the risks that a full life requires.

Based in part on his reading of the philosopher Friedrich Nietzsche, Rank had an existential understanding of death; he believed loss and limitation are part and parcel of everyone's lives, but that we tend to avoid and deny that reality. Therefore, for Rank, it is important for clients to acknowledge and come to terms with the inevitability of death; one way they do this is through dealing with time-limits, such as the necessary ending of the therapy relationship. Freud's view is sometimes characterized as pessimistic. He saw humans as subject to powerful instincts or drives, such as the drives toward sex and death. Rank, on the other hand, viewed his clients as capable of creating their own futures though acts of will, that is by taking responsibility for their own actions, challenging even death,

and by tapping into the creative resources available to each of us, but largely unused. Rank encouraged his clients to live fully 'in spite of' the inevitability of death and limitations.

In Rank's view, the human personality itself is a creative project. We are not hapless victims of fate, chance, genetics, or early upbringing; instead, we are each capable of creating our own destiny, legacy, or in Rank's terms, we are capable of immortalizing ourselves. Rank based his approach on a belief in transformation and the possibility of change; he saw the human personality as a medium to be formed and modified in response to life's changing demands.

Since the days of his adolescent diary, Rank had seen himself as a creative person, and it is not surprising therefore, that the creative individual, the artist, is the central figure in Rank's emerging theory of personality first articulated in the mid-1920s. His theory is based on three character types: the normal or 'average' type, the neurotic type, and the artist type. (Originally, Rank also wrote about a fourth type, the 'criminal type,' which we might today call the sociopath.)

The average person is someone who is not likely to seek therapy. For this type of person, life with its inevitable limitations presents a challenge that each of us must endure. Conformity to societal norms and expectations is the way to avoid internal conflict, and get on with one's life. Rank considers this type of person well-adjusted, as able to adapt to external circumstances without feeling burdened or victimized.

'Neurotic' is a term that has fallen out of favor these days, but it describes an inhibited and overly-self-conscious type of response to daily living. Rank thought neurotics are characterized by an excess of psychological knowledge, and a desire to interpret their behavior rather than act. Neurotics attempt to rationalize and justify their 'I can't,' obscuring the 'I won't' that lies behind it. The last thing a neurotic wants is to change. Neurotic individuals feel conflicted; they know what they could or should do, but feel constrained, inhibited, and unable to act.

Rank used a powerful economic metaphor to describe the neurotic's situation: life is a loan and death is the debt. According to Rank, the neurotic refuses the loan, which is life, in hopes of avoiding paying the debt, which is death. This is a superstitious approach to life, and one based on holding back, inhibiting, or postponing, rather than fully living. The neurotic person is plagued both by will, in the form of sensed inability to act, and by consciousness, manifesting itself as a relentless need to know. Rank saw neurotics as paralyzed and ineffectual in their actions, and insatiable in their introspective curiosity. At the core of this attitude is the neurotic's belief that what is needed is increased self-knowledge; that if only one knew oneself better one would understand why one does the things one does and why one feels the way one feels. Rank's insight was that the neurotic symptom – the apparent inability to act – is a distorted attempt at creativity. He proclaimed the neurotic a 'failed artist,' and encouraged the therapist to draw out the neurotic individual's creative resources to solve his or her own problems.

The Artistic Ideal

Rank thought every person was capable of creativity, but that some people typically responded to life's challenges by

attempting to live artfully. 'Artist,' for Rank, meant any person, regardless of their occupation. Thus scientists, musicians, mechanics, nurses, and painters are all capable of creativity. Rank's 'artist-type' is a person who lives fully in the present, overcomes personal and societal limitations, and makes a commitment to creating something enduring. In contrast to neurotics whose self-consciousness gets in the way of action, artists turn their energies outward; they come to know themselves as a result of their expressive actions in the world.

Rank's view of the artist, like many of the ideas he developed, stands in contrast to Freud's. In Freud's writings about artists like Leonardo da Vinci and Michelangelo, he emphasizes the artist's unconscious motives and the role of art in fulfilling wishes and desires. Although Freud appreciated art and collected historical art and artifacts, he tended to regard the artist's actions as an escape from conflicts and pressures into fantasy. Art, for Freud, was regressive – a return to an earlier, simpler time. Rank on the other hand, saw art as progressive; he believed works of art point toward something, that they refer not only to the past, but also to the future, and especially to the artist's own process of personality development. While Freud focused on the symbolism of the work of art and attempted to interpret its significance in terms of the artist's early life, Rank was one of the first psychologists to give attention to the creative process artists engage in, the actual making of art.

Artists are different. The creative process often involves doing something radical, something so new that it may not initially be understood. Rank believed that artists need to distinguish themselves from others. He thought it essential for the creative person to establish a separate identity, to nominate or appoint oneself as an artist, and in this way to assert one's difference. It is important for the artist to separate from existing conventions and styles in order to make a unique statement. He called this aspect of the process 'self-appointment'; it involves a conscious choice to live a creative life. The neurotic questions his or her identity: 'Who am I?' The artist's question is instead one about individuation: 'Who do I want to be?' Rank believed that self-appointment is the first step in the process by which artists are able to regard their differentness as uniqueness and originality.

But the path is not always smooth for the artist. The sense of being different in one's approach to life can be alienating and isolating. Society resists change and rewards conformity. From Rank's perspective, though, even a negative reaction to the artist and his or her work can be used constructively; artists need the resistance of the world against which to form their personalities. Artists, in Rank's conception, make a willing sacrifice; being misunderstood or unappreciated goes with the territory.

The obstacles to creation are not all external. Artists face, and must overcome, inhibitions – apparent failures of will – along the way. Rank understood this well and first wrote about it in 1914 in his scholarly book on *The Double* or *Doppelgänger*. In works of literature or drama the double appears as a substitute self who takes the place of the person. In Oscar Wilde's *Picture of Dorian Gray*, for example, the double is a painted portrait of the main character that gradually grows old while Dorian Gray remains forever young. Rank, with his continuing interest in folk beliefs and mythological themes, traced the idea

to pre-literate cultures in which the double is the soul of a dead person, appearing in a dream. At first the double is a haunting, uncanny apparition and a cause for fear, but is eventually interpreted by the dreamer's culture as reassurance that there is an afterlife. Rank saw that, in a sense, the double is a reminder that what we don't know can hurt us, that there is a realm outside our awareness and control, but that conscious action is the antidote to fear.

For creative individuals, the double is an alter-ego, a potentially inhibiting aspect of the self that hovers over the artist and causes grief by judging and criticizing, and ultimately, by shutting down the creative process. Artists, in other words, are sometimes confronted by creative block, an inability to produce due to seemingly self-created conflicts. Problems like procrastination and avoidance, self-consciousness, self-criticism, and perfectionism have often been seen as symptoms of fear of failure or fear of success. Rank thought creative block had more to do with fundamental issues of birth and death. Artists sometimes struggle to let go of their works – to give birth to them so to speak. By keeping the work from public view, the artist attempts to avoid both failure and success; the failed work may be a monstrous source of embarrassment, but the successful work is problematic too: it represents a standard one can never meet, a success that can never be achieved again. Thus the work that has gone before as well as the work that is yet to come can both be sources of inhibition. In *Art and Artist*, Rank's most important book, published in 1932, he described an artist's way out of the dilemma of creative block: the two works. Rank noted that artists sometimes divide their attention between two projects simultaneously. The two works may represent different styles, they may be carried out in different media, or they may be executed in different locations. Rank thought keeping creativity going even when one feels stuck was the key to overcoming blocks and inhibitions. Rank himself was extremely prolific perhaps in part because he typically had several projects in the works at once.

The artist also struggles with the existential reality of limitation: the limitations inherent in the medium, the artist's own limited technical skill, and the limitations of time and energy in each person's life. The artist whose work is perpetually in process and unfinished is denying the real limitation that death imposes on life; that is to say none of us lives forever; each of us is mortal. For Rank the will at its highest stage is a creative urge to go beyond even the final limitation of death by immortalizing oneself in creative works. Artists who come to terms with both personal limitations and the limitations of the external world need not despair; instead, they can attempt to make a mark on life for all time, and in this way transcend death. Artists, according to Rank, make voluntary sacrifices. They invest their time and energy in creative pursuits, forgoing other pleasures and desires; they live life fully without attempting to cheat or bribe death. Their creative work is intrinsically meaningful and rewarding. For some rare individuals the works live on and have an enduring impact beyond the artist's life, but even if the person does not achieve this kind of immortality, the way the artist lives his or her life – consciously and willingly immersed in creative action – is what is important.

Rank identified with both ideal and real artists. He thought of himself at first as one of the rare individuals Freud singled out as constitutionally predisposed to creativity. It is clear

that Freud considered Rank especially suited to the tasks he had in mind. This, coupled with the respect and admiration he initially received from his colleagues, must have contributed to Rank's sense of himself as a specially gifted person.

Rank's avid interest in art provided him with larger-than-life heroes. Among those we know he admired to begin with were Johann Wolfgang von Goethe, Fyodor Dostoyevsky, and Henrik Ibsen. Early in his life he called Richard Wagner his 'ideal leader and guide.' During the later, especially productive period of Rank's life, he associated with members of the artistic community in Paris and New York who flocked to see him, and in whom he saw himself reflected.

Rank's writing, first about mythological themes in psychoanalysis, and later about his own unique approach, and still later about the artist and his culture, became his art work. Although in his personal notes he frequently refers to great novels or dramas he was attempting, only Rank's psychological writings have actually survived him. Rank poured himself into his works, and they represent an achievement that can justifiably be called 'art.'

The years between 1924 and 1932 represent a very productive period in Rank's life. With his colleague Ferenczi, Rank published *The Development of Psychoanalysis* in 1924: in it they offered some of the first criticisms of Freud's method. They challenged the focus on the patient's early childhood experiences and the emphasis on the patient's transference toward the analyst. In so doing, they paved the way toward an approach to psychotherapy in which the real relationship between client and therapist is acknowledged and appreciated. Not surprisingly, the book was attacked by several Freudians, notably two of Freud's followers, Abraham and Jones. The publication of Rank's *Trauma of Birth* that same year was too much for the Freudians to take; it seemed like heresy for Rank to suggest that the client's anxiety might arise from the trauma experienced in separating from the mother (at birth, at weaning, and when the child takes his or her first independent steps). That the relationship with the mother might be even more significant than that with the father was seen not as the post-Freudian revolution it represented, but as anti-Freudian, deviant, and even deluded.

Rank was turning 40 and separating from his mentor and surrogate father, Freud, after almost 20 years at his side. In the summer of 1924, when Rank visited The United States, it was as Freud's emissary and as a teacher of psychoanalysis. He was greeted by an eager audience of social workers and psychologists more interested in his therapeutic innovations than in orthodox analytic method. What Rank offered was the first active psychotherapy, a time-limited approach, in contrast to the seemingly endless process of psychoanalysis. The emphasis on the actual relationship between therapist and client gave the therapist an active role and allowed the therapist to address the emotions that arose in the relationship rather than interpreting the fantasies projected onto the therapist. The client's new emotional experiences in therapy were a necessary complement to the intellectual understandings possible in analysis. This was a precursor to the idea that therapy provides a 'corrective emotional experience,' introduced by Franz Alexander years later.

The appreciative reception Rank received at his lectures in New York and Philadelphia buoyed his enthusiasm, but he was

confused by Freud's reaction to his theories. Freud had responded warmly at first, but while Rank was in America, some of Freud's associates seized the opportunity to criticize him behind his back. On his return to Vienna in October, 1924, conflicts between Rank and Freud were more conspicuous. Rank briefly recanted some of his views, but by 1926 it had become clear that their differences were irreconcilable; Rank severed his ties with Freud's committee, resigned from his various editorial positions, and moved to Paris to set up a practice on his own. Back in New York and Philadelphia that year for lectures, Rank was now explicating his fully independent approach. Shunned during a chance encounter with his former friend, Ferenczi, in New York, Rank was now convinced he needed to speak for himself. Rank's membership in the American Psychoanalytical Association was revoked a few years later, and all those he had analyzed would now need re-analysis by more orthodox practitioners. The separation from what had become Freudianism was now complete.

Although hurt by the rejection, these events only served to stimulate Rank's independence and creativity, which was evident in his prolific writing during this period. His work included books that took a broad social and cultural perspective on religion, education, and art. Rank turned his own painful experience of separation into a creative act of willing. He was interested in how easily an interpretation can become a tenaciously-held belief or ideology, as he called it.

Psychology and the Soul, first published in 1930, challenged other psychological interpretations. Freud had a materialistic and scientific view of religion. He had called religion an illusion, and predicted it would have limited importance in the future. Carl Jung had studied religious writings in his search for universal symbols or archetypes, but skirted the topic of the function of religious beliefs. Rank looked at religious beliefs as natural human phenomena – as ways of collectively dealing with primitive fears, and making life meaningful and significant even in the face of death. Returning to a theme he previously developed in his work on the double, Rank traced the idea of a soul to the recurrent 'urge to immortality.' Rank's study of anthropology informed his theory that this urge is manifest in various forms: in the belief in a soul that lives on after physical death, in the belief in reincarnation, in ancestor worship, and in beliefs that one's group or society has special access to immortality through ritual or divine intervention. Rank thought that for individuals living in a more psychologically-minded, post-religious era, immortality was something to be achieved through one's creative legacy, through works that continue to have a life even after the person's death.

Psychology and the Soul also established Rank as a thoroughly modern thinker. For example, Rank thought soul-belief was a product of one's ideology, and attributed Freud's criticism of religion to his nineteenth century reductive, causal, and materialistic scientific thinking. Rank was by this time reading the latest scientific theories of Albert Einstein and Werner Heisenberg. He argued that notions like relativity and indeterminacy made it difficult to support a mechanistic, causal scientific attitude. He advocated factual relativism, the understanding that so-called 'facts' are actually interpretations, and criticized psychoanalysis for its insistence that repetition of the past is more important than even actual experience in the present.

The same year *Art and Artist* was published in 1932, also saw a book called *Modern Education*. Here again, Rank challenged an ideological approach. Freud had interpreted the child's behavior in terms of sexual striving, while his follower, Alfred Adler, had regarded the child as seeking power and recognition. While he saw in both of these approaches an advance over authoritarian educational systems of his day, he felt neither adequately addressed the emerging will of the child. Rank felt the child's independent willing was stifled by educational ideologies that reward conformity and suppression of feeling. Rank thought parents had a vital role in understanding and acknowledging the child's spontaneous expressions of emotion. Rank also proposed an alternative to education primarily designed to help the individual learn a vocation. He thought discovery of one's skills and talents was a lifelong process, and he encouraged supporting self-exploration rather than training the person to fit a pre-determined job-description. Rank was himself an interdisciplinary thinker and an inspiring educator who, through his teaching and his example, influenced numerous psychologists and social workers to find their own integrative paths.

By 1934, Rank's ideas were becoming known; his lectures were well received and some of his books had been translated into French and English. Rank resisted establishing a school of Rankian therapy, having seen for himself what can become of one's ideas in the hands of zealous followers who could become dogmatic and, in his terms, 'ideological.' Rank separated from his wife Beata, who several years later moved to Boston where she set up a psychoanalytic practice with children. Rank's secretary in Paris, Estelle Buel, an American, came along in 1935 when Rank moved from Paris to New York. There he continued lecturing and practicing. He spoke at Harvard, where he impressed the important American personality psychologist, Henry Murray. At a lecture in Rochester, New York, the following year, a young Carl Rogers was in attendance. The publication in 1936 in English of Rank's theory of psychotherapy (two volumes: *Truth and Reality*, and *Will Therapy*), introduced his approach to an even wider audience. In contrast to Freud's emphasis on the unconscious and instinctual drives, Rank saw conscious choice and intention as critical. His approach emphasized a creative, improvisational therapy in which the relationship between client and therapist in the present, or 'here and now,' was paramount.

Beyond Psychology

From 1937 until 1939 Rank worked on a draft, in English, of what was to be his final book, *Beyond Psychology*. As suggested by the title, at this point in his life, Rank was advocating an alternative to what he considered the overly rational and reductive attempt to explain human behavior scientifically, the tendency to 'psychologize.' He returned to several of the themes he had dealt with previously: neurosis is not the result of societal inhibitions or repression of impulses, but the attempt by the neurotic to exert excessive control over his own nature; Rank called this 'willing the spontaneous.' Returning to a recurrent theme in his work, he saw the double as representing: first the shadow or identical self, next the person with his or her past, and finally the immortal self. Again contrasting his 'constructive' experiential therapy with psychoanalysis, he regarded the

task of therapy as helping the client's steps toward life fully lived, not more interpretation. He challenged several of Freud's assumptions: that bringing the unconscious into conscious awareness is curative, that the actual unconscious is made conscious (and not just an interpretation of it), and that emotional expression in therapy is nothing but a projection, a transference onto the therapist. Rank claimed that what is unconscious is the 'life force' itself, the dynamic spark that animates everyday existence. Rank's final message in *Beyond Psychology*, which was published posthumously, was that the full meaning of human experience is not graspable with our rational intellect, and that we need to allow for the irrational in life.

The year 1939 was momentous. Rank had been in poor health, but having finished his draft of *Beyond Psychology*, in which he advocated a life lived fully, he was eager to get on with his own life. He traveled with Estelle Buel to the western United States. Once his divorce from Beata was finalized, he married Estelle in July. Returning to New York in September, just as the Second World War was beginning, Rank learned that Freud had died in London, relieved from his suffering by a morphine injection by his physician. Ironically, Rank was briefly hospitalized soon after with a kidney problem, and then struggled at home with infection and fever. Rank wrote to Jesse Taft, his first biographer, that despite his illness he was at peace with himself. On October 31, back in the hospital, he died from a reaction to medications used to treat his infection.

Rank's Immortality

Only recently has Rank's influence begun to be acknowledged. *The Denial of Death* by sociologist Ernest Becker, brought Rank's ideas to a broad spectrum of the intellectual community. A full biography has been published, Rank's influence on post-Freudian psychology has been explicated, and several of his major books have been re-translated and made available to a wider readership. Rank's American lectures, delivered by Rank in English, have also been published. Various myths and rumors about Rank (e.g., that he was mentally ill, that he was a 'fascist'), have also been debunked by serious scholars. Many of Rank's ideas about creativity, education, human culture, and psychotherapy have entered into the mainstream of thinking in psychology.

Rank's work has had impact in several fields. Creativity researcher Donald MacKinnon, who had had been introduced to Rank's thinking by Henry Murray at Harvard years before, found Rank's notion of the artist type invaluable in his study of architects. Rank's theory of creativity has also influenced Organizational Theory, especially in the 'action learning' approach to team building and group problem solving. 'Terror Management Theory' in experimental social psychology, owes a debt to Rank's ideas about death fear. Rank is also receiving attention these days for his ideas about soul-belief and the development of spiritual traditions across cultures. Rank's works have continually been held in esteem by scholars in the humanities and social sciences.

Rank's creativity speaks very directly to psychotherapists. Carl Rogers incorporated Rankian notions into his client-centered psychotherapy, and Rollo May acknowledged Rank's influence on his existential approach, as did Irvin Yalom.

Writer Paul Goodman considered Rank's work essential to the newly emerging Gestalt psychotherapy. Transpersonal psychology, as practiced by Stanislav Grof for example, has been influenced by Rank's thinking about birth trauma. Rank's emphasis on the early mother-child relationship, ego development, and the importance of the actual therapeutic relationship anticipated key features of post-Freudian interpersonal and relationship therapies. Depth psychotherapy approaches that acknowledge the importance of irrational and unconscious processes are indebted to Rank, as are experiential psychotherapies that call on the therapist's ability to improvise in the moment.

Rather than leaving behind a school of thought or an ideology, Rank left a body of work that continues to inspire. He refused to become an inhibiting precursor, whose ideas become rigid and petrified in the hands of dutiful followers. Rank instead stepped aside to allow future psychotherapists to discover their own unique ways of eliciting their clients' creativity and resourcefulness. Over the years writers like Anais Nin and Henry Miller, as well as other artists, were drawn to Rank, in part because they felt understood by him, and especially because he resisted tampering with their creativity. Rank left artists alone, believing that the last thing they needed was more analysis, more psychological interpretation. A creative person who was not fully appreciated in his own time, Rank spoke with prescience about the future of psychological thought and practice. Rank's legacy is a creative, improvisational, approach to life that is constantly being rediscovered.

Remote Associates

E C Fairweather, University of Georgia, Destin, FL, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Associative theory of creativity Notion that creativity results from forming unusual or appropriate combinations between uncommon responses to given stimuli.

Concept attainment The formation of rules or categories about objects or ideas based on repeated experiences to various stimuli related to them. For example, an individual develops and refines the category 'cat' after repeatedly encountering and interacting with various forms of cats (pictures of cats, live cats, stories about cats, etc.).

Remote associates The less common responses evoked by a given stimulus, or in the context of creativity, by elements being considered in a creative activity. Responses that appear at first to be unrelated (or very distantly related) can be

brought together through connections made by a response that is uncommon for each of the elements, remote associates, but common to all of them.

Remote associates test (RAT) A measure of creative thinking developed by Mednick and Mednick consisting of problems with word triads which are solved by the generation of a fourth word for each problem that is remotely associated to each of the words in the triad.

Word association tests Measures of conceptual understanding in which individuals are asked to generate word responses. Individuals can make free associations to word stimuli in which they respond in any way they desire, or they can be given directions to respond in a certain way, for example, make unusual responses.

Introduction

Remote associates form the basis of Sarnoff Mednick's associative interpretation of the creative process which he put forth as an explanation of "processes that underlie all creative thought." Using the experiences of a host of creative individuals, particularly Henri Poincaré, as evidence for his theory, Mednick claimed that the creative process is "the forming of associative elements into new combinations which either meet specified requirements or are in some way useful" (1962, p. 221). To measure creativity under these terms, Mednick and Martha Mednick, with the assistance of Sharon Halpern, ultimately devised an instrument, named the Remote Associates Test (RAT), which is still widely used in research. Since his initial work was published, the term 'remote associates' has come to be used when referring to the 'mutually remote elements' that are combined during the creative process.

Mednick's Associative Theory of Creativity

Mednick developed his associative theory of creativity using literature related to concept formation. As discussed in this literature, concepts are more easily formed if the stimuli in which the concepts are presented evoke the same or similar associations over repeated encounters. Word association tests were used to examine concept attainment in order to determine individuals' various associations to presented concept stimuli. Like others espousing associative views of creativity, Mednick believed that remote associations, as indicated by unusual responses on these word association tests, were indicators of originality and thus creativity. The more remote the associates, the more creative the result. As a distinguishing feature of his theory, however, Mednick emphasized the "imposition of requirements on originality" in order for creativity to be achieved. Unusual responses may be original,

he claimed, but they may not be relevant. Creative individuals find remote responses that are appropriate to the constraints of their situation.

Mednick outlined three methods of achieving a creative solution by means of bringing together remotely associative ideas.

1. *Serendipity*: Finding a creative solution when two or more concepts, or their associations, are placed near each other, usually by accident. An example is the discovery of penicillin which was a result of Alexander Fleming accidentally leaving open a Petri dish containing *Staphylococcus* culture which was then tainted by mold.
2. *Similarity*: This type of creative solution occurs when the concepts or their associations are similar. Examples here include rhyming words, musical tones and harmony, colors, and natural themes. These creative solutions would occur most likely in creative domains in which the use of symbols is not required such as painting and music.
3. *Mediation*: This method is what is suggested by the term 'remote associates.' Here an individual uses a mediating concept that acts as a bridge between the initial concepts. Mediation is helpful in creative situations when the use of symbols is necessary, such as in the sciences. As an example of this principle, an individual studying creativity and depression might join the two by mediation with the common associate neurochemicals, as is being done in current research.

Mednick believed that individuals differ in the likelihood in achieving creative solutions. First, he stated what he seemed to consider a given; individuals with more information are more likely to make creative combinations. Beyond this basic element, he predicted that differences in probability and speed of attainment of creative solutions would be related to differences in individuals' organization of and accessibility to their associations, measured by what are called associative hierarchies.

In developing the idea of associative hierarchies, Mednick relied again on the work related to concept attainment. Concept associations could be ranked in their order of likelihood of response and this rank level correlated with attainment of the concept involved. Associative hierarchies are the relative strengths of the various associations individuals make to a given stimulus. Concepts ranking higher in associative hierarchy to a set of nouns would be more quickly attained than concepts that had lower levels of association with the same set of nouns.

Many individuals, according to Mednick, make predominantly stereotypical responses to most stimuli, such as a response of 'chair' to the stimulus 'table.' These stereotypical associations being so strong, these individuals have difficulty making any other associations. Such individuals are said to have an associative hierarchy with a 'steep slope.' After the first or second typical response; their associative strengths drop off quickly. Others, however, have 'flat associative hierarchies.' Individuals with flat slopes take a little longer to come up with responses, and may begin with the stereotypical responses, but because the strength of these responses is not so strong, more, uncommon responses come to mind as well. For example they may also respond to 'table' with 'chair' at first, but because this typical response is not so strong that it dominates their thinking, they will eventually respond with more remote associates such as 'periodic.' This concept of associative hierarchy, as depicted in graphic form by Mednick, is presented in Figure 1 which shows both a steep and a flat associative hierarchy for the stimulus item 'table.' Mednick predicted that less creative individuals would have a high concentration of association in a few typical responses and thus would be unlikely to be creatively productive. He predicted that, on the other hand, highly creative individuals could produce creative solutions due to the lowered levels of associated strength and thus the remoteness of their associated responses.

Mednick also pointed to the number of associations an individual makes, a variable related to associative hierarchy, as a factor in the likelihood of producing a creative result. Individuals with a steep slope will undoubtedly be less likely to produce a large number of associations to a given stimulus. Consequently, they would be unlikely to find an associate common to all elements in a given situation that would result

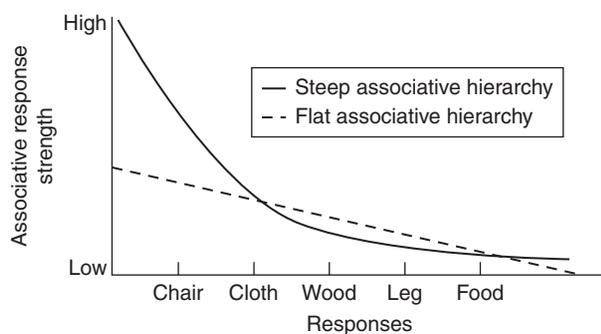

Figure 1 Posited associative hierarchies to the stimulus word 'table.' Adapted from Mednick, S. (1962). The associative basis of the creative process. *Psychological Review* 69: 220-232.

in a satisfying combination. Mednick also said that speed may not be an important factor in the number of associations an individual makes as time may be necessary for finding the associations that serve as mediators between the concepts involved in a given situation. Finally, Mednick proposed that individual differences may also occur as a result of cognitive styles and selection of the elements to be used as a source for creative combinations.

Individuals in many fields have taken advantage of these factors to boost their creative production. For example, humor writers use a strategy incorporating the making of remote associations as a means of generating ideas for cartoons, gag lines, and jokes. In 1990, Gene Perret, who named his version of this strategy "Random Associations," (p. 75) suggests that a writer make a list of about 50 "words, phrases, people, places, or things – anything at all" related to a topic under consideration. Perret recommends including atypical items on the list to increase the likelihood of uncommon or unexpected associations. After creating the list, the writer should peruse it, at first trying consciously to make unusual connections between some of the items and then letting the mind work unconsciously to make unusual connections. Writers can take a more focused approach by making specific categories within the overall topic and forcing unusual connections between random associations in the different categories. For example, a writer might use the categories 'people,' 'places,' and 'things' within the topic 'education' and generate the following associations in each of these categories respectively: professor, dissertation, expulsion, Little Tree; one room schoolhouse, desk, Colgate University, football field; and dictionary, pencil, school bus, essay. Then, the writer randomly would select one item from each of the categories and think of a way to link them together. Thinking of more and varied associations for each of the categories within the general topic likely leads to remoter connections between them. This remoteness is a key facet of creating humor. The linking of remote ideas brings about unexpected results, and the unexpected is the foundation for humor.

The Remote Associates Test

To test the associative theory and measure individual differences in processes fundamental to creativity, Mednick and Mednick, with Halpern, developed the RAT. Demonstrating that the test was in line with all aspects of his theory, Mednick stated that the test was designed to "provide stimulus elements from mutually remote associative clusters" to which individuals taking the test must "find a criteria-meeting mediating link which combines them." Although remote associates do not necessarily have to be thought of as a verbal construct, Mednick's test was based on earlier word association tests, and much of the research investigating this concept since his time has involved a similar structure.

RAT Structure

The RAT, which engages the individual in 'verbal associative habits that could reasonably be assumed to be familiar to almost all individuals brought up in the United States English

speaking culture' consists of 30 items. There are two forms of the instrument which is aimed at college age students and adults. Each item consists of a triad of words which are remotely associated to each other. The individual completing the RAT must come up with the correct fourth word which is remotely associated to the first three and joins them together. An example item is 'railroad,' 'girl,' 'class' for which the answer is 'working' as in 'working on the railroad,' 'working girl,' and 'working class.' The time allotted for the test is 40 min, and an individual's score is the total number of items answered correctly. The premise of the test is that individuals should be able to tap unusual associations to each of the stimulus words, by means of divergent thinking, to generate the remote associate common to all of them.

Establishing Validity of the RAT

During an initial study of reliability of the RAT, Mednick reported rates of 0.92 with a group of 289 college women and 0.91 with 215 college men. Validity was established in several ways. To establish criterion validity, RAT scores were correlated with faculty ratings of creativity among design students. This yielded a significant correlation of 0.70. In addition, a set of high and low RAT scorers at another university were each rated by one faculty member as being either high or low in research creativity, defined by the extent to which they had devised new research methods and put forth original research ideas. For the most part, the high RAT scorers were rated high on creativity and the low RAT scorers were not rated high on creativity. Finally, Mednick used results on word association tests as a means of building construct validity arguing that the more associations to which an individual has access the more likely he/she will be to make a creative combination with these associates.

Mednick examined the relationship between RAT scores and personality characteristics associated with creativity as a means of building validity. Significant differences in the attitudes and occupational interests between the high RAT and the low RAT scoring women were revealed. The high RAT scores demonstrated more 'atypical' and 'liberal' views than low scorers, for example, interest in occupations such as artist, psychologist, physician, mathematician, and author-journalist. On the other hand, low scorers preferred such occupations as farmer, math-physical science high school teacher, office man and pharmacist. Furthermore, Mednick reported that among architects RAT scores correlated significantly at a rate of 0.31 with scores on a scale of originality and -0.31 on a scale of conformity. In an effort to establish that the RAT was not a test of intelligence or verbal ability, Mednick found a modest negative correlation (-0.27) among the RAT and college grades.

Criticisms of the RAT

Others have not been convinced that the RAT is a valid measure of creativity. Despite Mednick's failure to find a relationship between RAT scores and verbal ability or intelligence, results from some later studies suggested there may be inherent verbal and intelligence biases in the test. In addition, there has been little to support Mednick's findings that RAT scores are related to other measures of creativity, especially measures

of overall creativity. In addition, in attempts to replicate Mednick's studies correlating word associations and RAT scores, little corroborating evidence has been found. In fact, in some cases, low RAT scorers actually produced more word associations than high RAT scorers. A more fundamental problem with the RAT is its effectiveness in measuring the very thing it purports to measure, the making of remote associations. Critics have pointed out that test items may favor structural associations over functional, or semantic, ones. For example, the RAT is criticized for having too many idiomatic associations and associations based on words that commonly appear together in the language like 'square' and 'deal.' Others have been concerned about the remoteness of the associations needed for success. After an analysis of the items on the RAT, one group of researchers concluded that the remoteness of response words from the stimulus words was not consistent throughout the test.

Other Forms of the RAT

The RAT has been adapted into many different language and cultural forms so that it can be used with other populations than the adult, English speaking population for which it was developed. These new forms of the RAT are used primarily for research purposes. The Mini Rat, an alternate form of the RAT, was designed by Mervin Lynch for administration among elementary school-aged children to determine the effects of teaching practices on creative potential. The instrument, which is administered orally, consists of 20 word doublets to which students provide a third word equally associated to each of the words in the doublet. Examples from the Mini Rat are: (1) pine/ice cream – answer: cone; (2) ahoy/shape – answer: ship; (3) peanut/fly – answer: butter; (4) water/Autumn – answer: fall. Split half reliability rates of 0.78 and 0.79 were found on two different forms of the Mini Rat, respectively. Noteworthy differences were recorded between groups described as high and low level creative students.

To deal with the structural flaws found in the RAT, Blaine Worthen and Philip Clark created the Functionally Remote Associates Test (FRAT). The specific goals for the FRAT were to construct items that had low or moderate functional associations but very remote structural associations, not too extreme in remoteness in free association response, and an appropriate level of difficulty. Analyses of the FRAT showed it to have promise as an alternative to the RAT. Recently, a list of 144 compound remote associate problems was developed by Edward Bowden and Mark Beeman for use in research related to insight in problem solving. The list was intended to provide a larger pool of items available in the RAT and provide a set of items with more consistency. Each item contained a triad of words the solution to which was found by forming a compound word with each of the words. Reliability rates for these items were fairly high, between 0.71 and 0.93; however, the authors may have created a list more structurally associated rather than functionally associated compound words.

The RAT has also been used as the basis for remote associates tests in different languages and/or for different cultures. The Paramesh Remote Associates Test (PRAT), a 71-item Tamil language remote associates instrument, is used to measure creativity among adolescents. Another adaptation of the RAT

was constructed in the regional Indian language Orissa. In addition, the RAT was modified to make a Jamaican culture-specific instrument for measuring creativity.

Improving RAT Scores Through Training

Researchers have postulated that free-association training would enhance RAT scores. In an early study investigating this premise, participants were trained by being asked to respond repeatedly, with a different association each time, to one stimulus and then again to another stimulus for a number of stimuli. This training procedure failed to improve RAT scores. Arguing that successful performance on the RAT is a result of the act of generating many associations, Jonathan Freedman tried a different approach to enhancing RAT scores. Freedman divided 90 college students into three groups. Individuals in one group made free associations to each of ten words and individuals in a second group wrote definitions to the ten words. Words used were unrelated to RAT items used later. A third group was comprised of individuals who, instead of generating their own associations, read those generated by the members of the first group. Overall, the group that engaged in free association scored significantly higher than the group that wrote definitions. Although the third group had the same words available to them as individuals in the first group, their RAT scores were significantly lower than the first group. This led Freedman to conclude that it is making the associations rather than the associations themselves that is important in RAT performance. A later replication of Freedman's study, with adaptations, showed conflicting results. No differences emerged between participants in groups who either made associations or read associations made by others in a first experiment. However, retraining in the middle of RAT administration resulted in higher RAT scores of participants who generated multiple associations to stimulus words than participants who either defined words or read associations made by others.

Factors Related to Remote Associates Abilities

Since the creation of the RAT, a number of factors have been linked to associative processes believed to be part of creativity. The RAT and other similar instruments have been used to study the extent to which variables such as stimulation through novelty, level of attention, and affect are linked to the making of remote associations.

Attention

As part of his theory of creativity, Hans J. Eysenck proposed that overinclusive, or original thinking, which he claimed is best measured by word association tests, is a trait of creative individuals. According to Eysenck, overinclusive thinking for creative individuals, like schizophrenics, may occur because they exhibit less attentional filtering and thus extend attention to a wider array of information. As a result, creative individuals have access to more and unusual associations when confronted with a stimulus. Unlike schizophrenics, though, creative individuals make associations that, while unusual, are also relevant.

Recent research employing the RAT supports the notion that the making of unusual associations may be linked to attention capabilities. Colin Martindale used neural network theory to link remote associates and attention. According to neural network theory neurons and/or clusters of neurons in the human brain that are activated at the same time and/or are in close proximity of each other are likely to become associated with each other. Later when one of these neurons or neuron clusters is engaged, the others are activated. Martindale relied on this theory to explain how defocused attention is related to making unusual associations. Martindale explained that the neural network system has a built in safety valve, called lateral inhibition, which keeps the overall level of neuron activation relatively constant. As a result, when individuals actively focus on a task, their arousal level increases activity among the most relevant neurons while nearby 'irrelevant' neurons are inhibited. This can potentially block associations. According to Martindale, defocusing attention allows for equal levels of activity throughout the neural network which results in activation of a wider range of neurons. This in turn allows for connections to be made among a broader range of thoughts, concepts, or memories. Martindale proposed that cortical arousal was a means of determining level of focus of attention. Measuring cortical arousal using electroencephalograms (EEG), Martindale found that at higher levels of cortical arousal individuals made strong but few associations on the RAT whereas at lower levels of arousal they made weaker but more associations.

Need for Novelty

In explaining the differences between associational abilities between high RAT scores and low RAT scorers, John Houston and Mednick proposed that creative individuals receive some type of reinforcement when they tap into remote associates for novel production. To test their hypothesis, they administered the RAT and placed individuals into either a high scoring or low scoring group depending on their total scores. Then, individuals were asked to choose which of a pair of words (a noun and a nonnoun) they preferred. When individuals chose a noun, the examiner responded with a novel association, and when individuals chose a nonnoun, the examiner responded with a common association. After controlling for preference for noun or nonnoun, Houston and Mednick found a significant difference between the two groups. The number of nouns chosen by members of the high RAT scoring group increased whereas the number of nouns chosen by the low scoring RAT members decreased. Support for their work was found in a later study in which a measure of need for novelty predicted divergent responses to a word association test. However, later replications of Houston and Mednick's study did not yield any significant results. Colin Martindale proposed that creative individuals, as defined by high scores on the RAT, may seek novelty to increase their level of arousal.

Incubation

The associative theory of creativity has been used to explain what processes may occur during the incubation stage, the second stage of Graham Wallas' four stage theory of the

creative process. Mednick and his colleagues used RAT performance to demonstrate incubation effects. Individuals were given a set of RAT items to complete. Then experimenters primed the individuals with the answers to half of ten items they missed. This was done by asking them to complete a set of analogy problems, some of which contained answers to the problems they missed. High creative individuals, as defined by previous scores on the RAT, gave significantly more corrected responses the second time around than the number of corrected responses given by low creative individuals. According to Mednick and his colleagues these findings supported an associative view of incubation. Although the idea of incubation itself has met with skepticism in the past, recent research replicating and refining that of Mednick and his colleagues continues to provide mounting evidence for their claims and the phenomenon of incubation as a whole.

Mood/Affect

The associative view of creativity has been used as a bridge in linking affect with creativity. Eysenck suggested that word association tests provided the best means of determining creativity because they located the point in a continuum between normality and psychosis which could be identified by a point in a continuum between common and bizarre associations to words. On the affective side, he labeled this point 'psychoticism' and on the creative side he labeled this point 'originality.' Much of the research verifying and expanding on Eysenck's work has been done with word association tests. In addition, word association tests have been used in studying the relationship between schizophrenia and mood.

The RAT, and other similar instruments, on the other hand, have been used, particularly recently, to link creativity to everyday moods rather than to psychopathology. Positive affect has been shown to increase RAT scores and individuals' ability to judge the extent to which varying levels of related word triads adapted from the RAT are in fact related. In some cases, judgments of coherence, under positive mood conditions, may be overcorrect, that is judgments of coherence were given even when triads were weakly related. Both spread of activation and broadened attention have been suggested as the mediator between positive affect and enhanced capability of making connections between remote associates. Varying mood has also been implicated in remote associates performance. In one study by E. M. Fodor, individuals who showed a bipolar inclination, though were not at a clinical level, performed significantly higher on the RAT in an enhanced mood than all other participants, including other individuals with bipolar inclinations who did not have their mood manipulated.

Conclusion

Mednick had a profound effect on the field of creativity when he introduced his associative theory of creativity. Although his theory was not an entirely new idea, he provided much support for his theory including a means for measuring it. Many of the criticisms of his theory and his test are warranted. Still, the idea of remote associates is one that has merited the attention it has received and deserves further investigation. New developments in the area of neuroscience may enlighten us as to what processes underlie the making of remote associations and how these processes are related to creativity. Research related to spreading activation and neural network theory is another means of bringing this concept to light. In addition, burgeoning research in the area of mood and creativity may help to bring greater understanding of how individuals differ in their ability to make remote associations and what this means for their creative capabilities.

Glossary

Cognitive creation approach An approach that emphasizes creative capacity as an essential property of normative human cognition and suggests that the relevant processes are open for investigation.

Cognitive neuroscience approach An approach that involves relating cognitive functions to their underlying basis in the brain.

Confluence-theories approach An approach which assumes that multiple components must converge for creativity to occur.

Creativity A process in which one generates a contextually and culturally original and valuable product within a certain domain.

Insight problem An open problem that has a closed solution; it typically requires the mental restructuring of problem information, which leads to a clear and immediate understanding of how to solve the problem.

Working memory An executive and attentional aspect of short-term memory involved in the integration, processing, and retrieval of information.

What Is Creativity?

Definition of Creativity

Creativity is an important ability to have if one is to remain flexible and cope with the problems and changes that are a part of our daily lives. Creativity is a process in which one generates a contextually and culturally original and valuable product within a certain domain; moreover, a creative product or outcome is the result of the interaction of personal characteristics and the environment. Since J. P. Guilford's speech advocating the systematic study of creativity in 1950, creativity has been studied in a great variety of disciplines. Definitions of 'creativity' have evolved from the unidimensional to the multidimensional plane and from factors related to personal characteristics to those concerning social milieus.

Elements of Creativity

Creativity is comprised of certain basic elements that are nurtured through the accumulation of various life experiences. The nature of these experiences may very well be affected by personal characteristics, family environment, schooling, and even one's social milieu. Among these influential factors, personal characteristics have the most direct and greatest influence on creative performance. Such characteristics can be divided into categories of knowledge, disposition (attitudes, tendencies, and motivation), and skills. A sound knowledge base is essential to the development of creativity, and the ability to build new structures is at the core of knowledge-building. Creative thinkers require both the knowledge of a particular domain and that of cross-domains. As for their disposition, creative individuals are usually curious, willing to share ideas, brave enough to express themselves, and highly motivated to learn and achieve self-improvement; they also attempt to solve different problems and have a persistent urge to keep on trying. Finally, the skills required for creative performance include both cognitive and metacognitive skills. Creativity is the ability to transform materials into new and original forms; it is also regarded as a metacognitive process in which such

metacognitive abilities as planning, monitoring, and evaluating cognitive operations are required.

Types of Creativity

Creativity can be divided into four categories: mini-c, little-c, pro-c, and big-c. To date, most investigations of creativity have focused on big-c and little-c. The creativity types mini-c and pro-c were recently proposed. Big-c creativity consists of eminent creative contributions. The goals in studying eminent creativity are to learn about creative genius and to discuss what creative works may last forever. Typical creators who might be studied are eminent classical composers whose works have lasted for centuries, the winners of prestigious awards, or great inventors whose inventions have had a great impact on human civilization. Examples of those who are classified as big-c are Mozart, Einstein, and Darwin.

The study of little-c is based on the assumption that creativity is part of human nature and can be found in average people's everyday lives. For example, a person may creatively paint his/her room to look like a blue sky. Such everyday creativity is called little-c. Most studies that focus on students or children examine this type of creativity. The little-c category is important for identifying and nurturing creativity at home and in schools, the workplace, and social settings.

Mini-c creativity refers to novel intrapersonal insights about and interpretations of personal experiences or actions; it highlights the personal and developmental aspects of creativity. For example, a four year old boy told his mother that he wants to have a 'rocket bicycle' because it could take him to any place that he wanted to visit immediately. The little boy had a mini-c insight about combining two things he loves: rocket and bicycle. The mini-c helps to explain young children's creativity; it is useful for distinguishing between the genesis of creative expression (mini-c) and the recognizable expressions of creativity (little-c).

Pro-c represents a level of developmental progression and effort that extends beyond that of little-c but does not reach that of big-c yet. People who attain professional-level expertise in any creative area are likely to have pro-c. For example, an individual of this nature might be a professional composer

who makes a living composing songs for famous singers. However, not all working professionals in creative fields can reach the pro-c level. Prominent creators may require 10 years of preparation in a domain to become world-class experts.

Evaluation Indices of Creativity

The great majority of creativity studies have been based on divergent thinking tests, which are open-ended and designed to assess the ability to generate novel alternative solutions. Performance on these tests is usually scored based on three indices: fluency, cognitive flexibility, and originality. Fluency refers to the number of unique ideas or problem solutions that are generated, while flexibility refers to the number of categories that a person accesses; it reflects the capacity to switch approaches, goals, and sets. Finally, originality refers to the uniqueness of an idea; it reflects the ability to approach a problem in a novel way. Because fluency and flexibility are contagious and because of the development of creative theories, the consensus is that the evaluation of creativity must include originality (or novelty) and valuation (usefulness or appropriateness).

Is Creativity Domain-General or Domain-Specific?

The debate over whether creativity is domain-specific or domain-general includes three important perspectives. The first perspective is that creativity is a domain-general trait; that is, creative individuals can be creative in many domains. Studies based on the psychometric approach usually assume this perspective. The second perspective is that creativity is domain-specific; that is, people who are creative in one area are not necessarily creative in other areas. Studies based on socio-cultural and problem-solving theories support this domain-specific perspective; when tasks reflect the domain of expertise, expertise plays an important role in creative problem-solving. The third perspective, discussed by J. A. Plucker and R. A. Beghetto in 2004, is that creativity has both specific and general components. Such a hybrid model suggests that the level of specificity may change with the social context and with development through childhood into adulthood, and while some general factors may influence creative performance in all areas, only several domain-specific factors will influence creative performance in specific activities.

Development of Research Approaches and Models of Creativity

Approaches for Creativity Research

The study of creativity can be traced back to Plato, who argued that a poet is able to create only when the Muse dictates; however, more scientific and systematic studies of creativity started after the psychometric approach was proposed in 1950. The development of creativity research included eight approaches.

1. The mystical approach regards a creative individual as an empty vessel that a divine being can fill with inspiration. The individual will then pour out the ideas with which he has been inspired and form a creative product.
2. The pragmatic approach primarily concerns the development of creativity, and most studies are not concerned with testing the validity of creative ideas.
3. The psychoanalytic approach hypothesizes that creativity is derived from the tension between conscious reality and unconscious drives. Case studies of eminent creative persons are examples.
4. The psychometric approach claims that creativity can be studied in everyday subjects using paper-and-pencil tasks. Such tasks usually measure creativity based on fluency, flexibility, and originality.
5. The cognitive approach seeks to understand the mental representations and processes underlying creative thought.
6. The social-personality approach focuses on personality variables, motivational variables, and social culture environment. Through correlational studies and contrasts between high- and low-creativity people, many potential traits have been identified.
7. The confluence-theories approach assumes that multiple components must converge for creativity to occur. Most recent studies are based on this assumption.
8. The cognitive neuroscience approach involves relating cognitive functions to their underlying basis in the brain. Via neuroscience instruments, brain activity during the process of creation can be specified.

While the first two approaches seem to damage the scientific study of creativity, the psychoanalytic approach can be regarded as the first major theoretical approach to studying creativity in the twentieth century. Moreover, the cognitive approach and social-personality approach were developed at about the same time. Recently, the cognitive neuroscience approach has started to be employed in studies concerning the creative process.

Confluence Theories of Creativity

Most studies have defined creativity from the perspective of one of the '4Ps': personality, process, place/press, and product. More recent studies, however, have interpreted creativity from a more holistic, dynamic, and multidimensional perspective due to the flourishing of the following confluence theories.

Componential model of creativity

This model suggests that three components are essential for the production of original responses or works. These three components are domain-relevant skills, creativity-relevant procedures, and task motivation. Domain-relevant skills include technical skills, factual knowledge, and special talents in a given domain. Creativity-relevant procedures are composed of cognitive styles, work styles, and the application of heuristics to exploring new pathways. Task motivation is comprised of motivational variables that determine an individual's approach to a given task. The level of creativity varies as a function of the strength of each of the three components.

Evolving system model of creativity

The characteristics of this model are three-fold: (1) the creative person is unique; (2) developmental change is multidimensional; and (3) the creative person is an evolving system.

Creative people do not follow some well-charted path; they are unique in unexpected ways. The notion of an evolving system emphasizes that development is multicausal and that reciprocally interactive relationships exist both among the internal elements of the system and between creative individuals and their external milieu. Additionally, the evolution of creative ideas is influenced by personal expertise, motivation, emotions, and environment. Moreover, creative individuals seek not just answers but also new questions.

Systems model of creativity

This model suggests that creativity is a process that can be observed only at the intersection of individuals, domain, and field. In this model, individuals draw on information in a particular domain and transform or extend it through their cognitive processes, motivation, or unique life experiences. The field, consisting of people who influence a particular domain, evaluates and selects new ideas. The domain, a culturally defined symbol system, preserves creative products and transmits them to other individuals and future generations. This model also emphasizes that individuals undertake creation within a particular domain and that, therefore, domain knowledge is required.

Interactive perspective of creativity

This model emphasizes the creative results of the interaction of three core elements: the individual, other persons, and the work. The individual can be a child or a master. As for other persons, when the individual is a child, the influential other persons are family and peers, whereas when the individual is a mature adult, they are rivals, judges, and supporters in the field. The work refers to relevant symbol systems in the domain or discipline. The model also suggests that three factors (symbol systems, mental skills, and ways of communicating in different domains) vary dramatically from one another.

Investment theory of creativity

This theory suggests that creative people are willing and able to buy low and sell high in the realm of ideas. Buying low refers to pursuing ideas that are unknown and/or out of favor but that have growth potential. These ideas are often intensely resisted by others when they are first introduced to them. Creative people persist nevertheless and eventually sell high. This theory suggests the confluence of six distinct but interrelated resources that are required for creativity: intellectual ability, knowledge, a particular style of thinking, personality, motivation, and environment.

Ecological systems model of creativity development

This is the most recently proposed confluence model; it suggests that four systems – the microsystem, mesosystem, exosystem, and macrosystem – have a far-reaching impact on an individual's development of creativity. The microsystem specifies inherent and learned personal characteristics: mainly knowledge, dispositions, and skills. These personal characteristics are the most fundamental to the generation of a creative product, and they directly affect all stages of the creative process. The mesosystem, meanwhile, consists of family and school experiences. These two subsystems interact with each other and greatly influence the creative potential of a person throughout

his or her childhood and even into his or her teens. However, as the creative person grows up, these influences may become more indirect and perhaps less influential. The exosystem is comprised of organizational factors that relate to an individual's work, including the people, events, and things within an organization. This system interacts with the creative person and influences the creative process both directly and indirectly. Finally, the macrosystem refers to a social milieu, including the values, laws, and customs within a culture. This system has a substantial impact on the evaluation of a creative product. From a mature adult perspective, the four layers of the system interact with one another, but only the microsystem and macrosystem directly influence the current creative process.

Approaches for Studying Creative Processes

Creative Processes

Some confluence theories have identified specific stages of creative processes. For example, the componential model of creativity indicates five stages of creativity:

1. problem or task identification, in which task motivation determines whether the search for a solution will begin or continue;
2. preparation, in which domain-relevant skills determine which pathways will be available during the search for a response;
3. response generation, in which creativity-relevant procedures serve as an executive controller and influence how the search for a response will proceed;
4. response validation and communication, in which domain-relevant skills determine which criteria will be used to evaluate a response; and
5. the outcome, in which an appropriate decision is made; the result of the outcome will, in turn, influence task motivation and further determine whether the process will continue or end.

Similarly, the ecological systems model of creativity development identifies four stages of creativity:

- preparation: collecting related information, and organizing it into schematic patterns;
- incubation: analyzing and synthesizing the information in the schema;
- insight: finding connections between information in the schema and forming a creative product; and
- evaluation: using the product and validating its originality and value.

On the other hand, the creative cognition approach claims that five types processes commonly occur during creation:

1. the retrieval of existing structures from memory;
2. the formation of simple associations among the structures or combinations thereof;
3. the mental synthesis of new structures;
4. the mental transformation of existing structures into forms; and
5. the analogical transfer of information from one domain to another.

Accordingly, creative processes are comprised largely of the retrieval, integration, and retention of knowledge, the close connections between cues and the activation of knowledge, the crucial role of motivation, and the contribution of incubation to insight. Exploring how these factors or components may actually interact in the process of creation, undoubtedly, is central to any understanding of creativity. To date, most studies based on one of the 4Ps or the confluence theories have employed a psychometric approach; as a result, how a creative solution is produced remains a mystery. The creative cognition approach and cognitive neuroscience approach may provide a new window into this mystery.

Creative Cognition Approach

What is creative cognition?

Cognitive creation emphasizes that creative capacity is an essential property of normative human cognition and that the relevant processes are open for investigation. It also emphasizes that creative ideas and products emerge via the application of ordinary, fundamental cognitive processes to existing knowledge structures.

Creative cognition seeks to move beyond traditional psychometric approaches to an understanding of creative thoughts. It has three goals. The first goal is to advance the scientific understanding of creativity by adapting the concept, theories, methods, and frameworks of mainstream cognitive psychology to the study of fundamental cognitive operations that produce creative thoughts. The second goal is to extend the scientific understanding of cognition by conducting experimental observations of the cognitive processes that operate when people are engaged in creative tasks. Finally, the third goal is to specify the factors and processes that determine how existing knowledge will be applied to new situations and the precise way in which such information can either facilitate or inhibit creative functioning. Some studies that involve understanding the cognitive process of creativity have undertaken the creative cognition approach.

Creative cognition approach

The major concern of the cognitive approach to creativity is how differences at the level of information-processing operations can influence creative performance. Early models within the creative cognitive domain suggest that the ability to be creative is influenced by the manner in which semantic networks are organized. Specifically, less creative people have steep associative hierarchies in semantic networks, such that a stimulus activates many closely associated or stereotypical representations and therefore generates few unique representations. Highly creative people, in contrast, have flat associative hierarchies, such that they have comparable access to both closely and remotely associated concepts and therefore generate more unique representations.

In the 1990s, a creative cognition approach called the Geneplore model was proposed that has been employed to studies of insight, the extension of concepts, recently activated knowledge, conceptual combinations, and creative imagery. This model seeks to distinguish the differences between the cognitive processes that are used in creative

cognition and the types of mental structures through which they operate. The central idea of this model is that many creative activities can be described as the initial generation of candidate ideas or solutions followed by the extensive exploration of those ideas. The initial ideas are sometimes preinventive in the sense that they are not complete plans for a product or tested solutions. Usually, one would alternate between generative and exploratory processes and refine the structures according to the demands or constraints of a particular task.

Cognitive Neuroscience Approach

The goal of cognitive neuroscience

Despite six decades of experimental investigation, there are still many open questions concerning the essential nature of creativity. For example, what operations are involved in creative thinking? How is creativity brought about by and implemented in the brain? Such questions concerning creative processes are central to the cognitive neuroscience of creativity. Cognitive neuroscience involves relating cognitive functions to their underlying basis in the brain; it helps us to find the link between creative activities and their corresponding brain dimensions.

Cognitive neuroscience and creativity research

Recently, neuroscience instruments such as functional magnetic resonance imaging (fMRI), positron emission tomography (PET), electroencephalography (EEG), magnetoencephalography (MEG), and event-related potential (ERP) have been employed in studies of creativity. However, most related studies have focused on brain symmetry; studies that focus on the cognitive abilities required for creativity and how insights are produced remain scarce.

The abilities required for creativity, such as working memory, sustained attention, and cognitive flexibility, are typically ascribed to the prefrontal cortex. Moreover, stored knowledge and novel combinations of that knowledge are implemented in two distinct neural structures – the TOP (the temporal, occipital, and parietal regions) and the prefrontal cortex. Such findings contribute to our understanding of the difference between creative and noncreative thinking.

However, a simple search for the brain regions involved in creativity would be fruitless. The involvement of the prefrontal cortex is presumably restricted to domain-general creative processes; when it comes to domain-specific aspects, other cerebral areas are more likely to be at work. It is also suggested that the creative insights that are produced after concerted deliberation and those that are generated spontaneously activate different regions of the brain. Moreover, a study conducted by fMRI found that expert subjects' creativity was quantitatively correlated with the degree of dominance of the right prefrontal cortex over that of the left, but only a negative correlation with creativity was observed in the bilateral inferior parietal cortex among the novice subjects. Therefore, when employing a comprehensive neuropsychological approach, it is essential to break down the underlying cognitive processes involved in creativity tasks and investigate the involvement of different regions of the brain in each of these processes.

Studies of Insights

What Are Insight and Insight Problem?

Creativity is generally conceived of as the generation of insights or problem solutions that are both novel and useful. Insight is the process through which a problem-solver reconstructs the problem and suddenly develops a solution after systematic attempts to find one. In essence, insights are sporadic and unpredictable exceptional thinking where unwarranted assumptions must be discarded before solutions to problems can be obtained.

Unlike divergent thinking tests, insight problems are commonly used when the cognitive approach is emphasized. An insight problem is characterized as an open problem with a closed solution; it typically requires a mental restructuring of problem information that leads to a clear and sudden understanding of how to solve the problem. The Duncker Candle task is a classic insight problem. Moreover, the process of insight problem-solving requires both convergent thinking and divergent thinking. It is convergent in the sense that it aims for a single correct solution. On the other hand, when the problem needs to be restructured by means of flexible thought, it requires divergent thinking.

Cognitive Neuroscience Approach of Studying Insight

The paradigm of studying insight has been extended outside the realm of traditional experimental design to incorporate cognitive neuroscience since the latter was developed. However, related studies have just begun to be developed. Creative insights can be the result of two processing modes, deliberate and spontaneous, each of which can guide neural computation in structures that contribute emotional content and provide cognitive analysis. The cognitive neuroscience approach is able to provide concrete evidence of such assumptions.

An ideal experimental paradigm for studying the neural correlates of insight with cognitive neuroscience instruments should have at least the following features.

1. Be able to elicit restructuring of the problem.
2. Elicit multiple insight events within a limited time period. Routine event-related fMRI or ERP studies require 10–50 trials in each condition to guarantee reliable analysis.
3. Allow one to test various kinds of research hypotheses, including general hypotheses derived from theories as well as hypotheses about the precise function of particular brain areas.
4. Enable researchers to define suitable reference states (i.e., the baseline). Brain imaging analysis relies heavily on the contrast between a target state and a reference state.
5. Allow one to study internally and externally triggered insights.

To elicit creative insight in a short time period, solution hints can be used. Such a design allows one to obtain multiple insight events and their accurate onset times, which are required for fMRI and EEG, and to reliably record the activity associated with the restructuring component of insight. Moreover, to relate the dynamic development of insight to neural

activity, implicit learning tasks can be employed; such tasks enable researchers to pursue the development of an insight on a trial-by-trial basis.

Studies of Emotions and Creativity

Emotional Valence and Creativity

Emotional valence includes positive emotions and negative emotions. Over the last 30 years, systematic studies have examined the relationships between emotions and creative cognition. Some experimental studies have found that a positive emotional state facilitates creativity, whereas others have found that a negative emotional state enhance creativity. The approaches to explaining the relationships between emotional states and creativity include the following.

Cognitive justifications

This perspective argues that positive emotional states influence an individual's attention, which enhances the possibility of combining different elements, facilitates access to positive material in one's memory, promotes the spread of knowledge activation, and increases the possibility of making remote associations conducive to creative thought, therefore facilitating creative problem-solving.

Broaden-and-build theory

This theory proclaims that positive emotions momentarily broaden people's attention and thinking, enabling them to draw on higher-level connections and a wider range of percepts or ideas, and thereby leads to creative thought. In turn, these broadened outlooks help people to discover and build consequential personal resources that contribute to the development of creative abilities.

Hedonic contingency theory

This theory assumes that happy individuals scrutinize the hedonic consequences of a particular action more carefully than do individuals in other moods and that they will choose actions that either maintain or improve their positive mood. Therefore, individuals in happy moods might be more creative because they are motivated to maintain or enhance their positive affective state.

Cognitive tuning theory

This theory suggests that negative moods indicate that the current situation is problematic and motivate actions designed to alleviate or eliminate the problem; creative solutions to the problem are thereby produced. In contrast, positive moods signal that the current situation is satisfactory and that no further action is necessary; creative thoughts are thereby inhibited.

The Interaction of Valence and Activation

The dual-pathway model suggests that mood states can be conceptualized in terms of two underlying dimensions – hedonic

tone (positive vs. negative) and activation (activating vs. deactivating). More specifically, cognitive activation is a necessary precondition for creativity, and hedonic tone determines the route (the flexibility route or the perseverance route) through which creative fluency and originality are achieved. In other words, activating moods with a positive tone is linked to cognitive flexibility and thereby promotes creative performance, whereas activating moods with a negative tone is linked to perseverance and thereby enhances creativity.

Research findings also suggest that the pleasanter one's emotional state and the greater the level of arousal, the more original ideas are produced. On the other hand, the more negative the emotional state is and the greater the level of arousal, the less likely it is that ideas will be produced. Moreover, the interaction between negative reactivity and level of arousal has an inhibitory effect; that is, when people react actively to negative stimuli, their creative ideas are inhibited because of increased arousal.

The Interaction of Valence, Activation, and Regulatory Focus

A three-dimension theory has been recently proposed to explain the relationship between one's emotional state and creativity; the three dimensions are hedonic tone (positive vs. negative), the level of activation involved (activating vs. deactivating), and its association with regulatory focus (promotion vs. prevention). Mood states that are associated with a promotion focus (e.g., anger, sadness, and happiness) should expand attentional scope and thereby facilitate creative performance, whereas mood states that are associated with a prevention focus (i.e., fear, relax, and calm) should produce a more constricted scope of attention and thereby impede creativity.

Based on this three-dimensional theory, a meta-analysis of mood-creativity research conducted over 25 years suggests that positive moods produce more creativity than do mood-neutral controls but that there are significant differences between negative moods and mood-neutral controls or between positive and negative moods. Moreover, creativity may be enhanced most by positive emotional states that are activating and with a promotion focus. Interestingly, negative, deactivating moods with such a focus are not associated with creativity, but negative, activating moods with such a focus are associated with lower creativity. Such findings need to be replicated to verify the validity of the three-dimension theory concerning emotion and creativity.

Studies of Working Memory and Creativity

What Is Working Memory?

Working memory is the executive and attentional aspect of short-term memory involved in the integrating, processing, and retrieval of information; it requires the simultaneous storage and processing of information. Recent studies have identified that the frontal cortex, parietal cortex, anterior cingulate, and parts of the basal ganglia are crucial for working memory function. Generally, the neural basis of working memory has been derived from lesion experiments in animals.

Theories of Working Memory

Multicomponent model of working memory

This model assumes that human thought processes are underpinned by an integrated system for temporarily storing and manipulating information. Four subcomponents are included in this model. The first is the central executive, responsible for directing attention to relevant information, suppressing irrelevant information and inappropriate actions, and coordinating the two slave systems: the phonological loop and the visuospatial sketchpad. The second is the phonological loop, which is comprised of a phonological store and an articulatory rehearsal process. The third is the visuospatial sketchpad, which manipulates visual images and spatial information. The fourth is the episodic buffer, which is a limited-capacity store that binds together information to form integrated episodes.

Embedded-process model

This model claims that the human memory system operates by way of rich interaction between attentional and memory mechanisms. Working memory is organized into two embedded levels. The first level is comprised of activated long-term memory (LTM) representations. The second level is the focus of attention. Attentional resources are used to stimulate information from LTM to meet current goals. Moreover, activated units can arise from sensory input as well as semantic and episodic information from LTM. Though one may or may not be consciously aware of these representations, they are readily accessible for use if necessary. A portion of these representations can be further promoted to a highly active state that comprises the focus of attention.

To date, most studies focused on working memory have employed the multicomponent model of working memory; in contrast, only a few studies have adopted the embedded process model.

Working Memory and Creativity

The multicomponent model of working memory suggests that a working memory buffer is critical for creative thinking. The dual pathway model also claims that activating rather than deactivating moods increase working memory capacity, thereby facilitating cognitive flexibility. It is also suggested that positive emotions may serve as a retrieval cue for positive material in memory, which leads to multiple interpretations and ways of organizing material in memory and therefore contributes to creative thinking.

Moreover, the cognitive network model of creativity indicates that a creative solution is a function of the degree to which frames that were previously distant from one another become saliently associated with one another through problem-solving. The frame is the basic unit of knowledge that is stored in memory. When the frames occupy short-term memory, they are salient; when two or more frames are simultaneously salient, they are associated. The association of remote frames is influenced by cognitive load and the sophistication of problem frames. When people use many salient frames simultaneously or use fragmentary frames to represent a problem, cognitive load may be high, and this may therefore

decrease the probability of combining remote frames and thus generate less creative solutions. However, when people chunk the problem into a sophisticated frame, cognitive load may be reduced and lead to more efficient short-term memory processing, which will ultimately lead to more creative solutions.

Cognitive Neuroscience, Working Memory, and Creativity

Findings from lesion, pharmacological, and preclinical studies indicate that the prefrontal cortex is a key brain structure in working memory. This is supported by neuroimaging studies showing a significant linear relationship between the increase in working memory load and the degree of activation observed in the dorsolateral prefrontal cortex.

Moreover, a few studies based on theories of working memory have been conducted to connect working memory and brain structure. For example, studies based on lesion location in patients and neuroimaging in normal subjects indicate that the basic components of working memory are localized in different brain regions. The phonological loop clearly involves the left temporoparietal region; visuospatial working memory is primarily localized in the right inferior parietal cortex, right premotor cortex, and right inferior frontal cortex. The nature of working memory is a topic that is difficult to tackle using purely behavioral methods, but neuroimaging studies are beginning to shed light on this complex process.

Conclusion

Creativity is commonly defined in terms of originality and valuation. Although there has been a long debate over whether creativity is domain-specific, most recent theories and research findings suggest that creativity is a domain-specific trait. However, compared to the domain-general realm, the domain-specific aspect of creativity is less well understood. If we are to develop a better grasp of domain-specific creativity, more studies are required that consider a single domain in depth and focus on examining the key ingredients of creative processes and people who differ across domains.

Creativity may be affected by personal characteristics, family environment, formal education, and even one's social milieu; personal characteristics, however, play the essential role during the creative process. Cognitive tests, such as those of divergent thinking, remote association and word association, have been commonly used to examine the relationship between creativity and its influential factors as well as to validate major theories of creativity. Only a few standardized domain-specific tests and insight tasks have been developed, and few studies have been conducted to test the complete confluence theories of creativity. Accordingly, more domain-specific creativity tests (especially those other than divergent thinking tests) and path models of the confluence theories based on empirical data need to be developed.

Among the many variables that have been shown to predict creativity, emotion stands out as one of the most widely studied predictors. Studies that focus on the relationship between emotions and creativity have gradually evolved from one dimension (valence) to two dimensions (valence \times activation)

and, recently, to three dimensions (valence \times activation \times regulatory focus). More empirical studies that focus on interactions among varied dimensions of emotions are required to establish the interaction theory of emotion and creativity. Moreover, in emotion-creativity research, it is suggested that activating mood states come together with higher levels of dopamine and noradrenalin and greater working memory capacity, thereby facilitating the restructuring of information and cognitive flexibility. Working memory is critical if creative thoughts are to emerge. Employing a cognitive neuroscience approach to examine the interrelationship among emotional states, working memory, and creativity would shed light on the relationships among these variables in terms of brain function.

Due to the development of cognitive neuroscience, the paradigm of studying insight has recently been extended outside the realm of traditional experimental design to incorporate cognitive neuroscience. However, related studies are still scarce. Further studies of insight that employ cognitive neuroscience instruments should take into account the aforementioned ideal experimental paradigm in order to broaden our understanding of how insights are produced.

In conclusion, the development of the research paradigm of creativity is basically in line with that of psychological studies. The cognitive approach, creative cognition approach, and cognitive neuroscience approach have focused on uncovering the mystery of the creative process and related factors. Studies that employ the cognitive approach have defined many mental operations involved in creative thinking: for example, attention, working memory, and emotions. The way forward would be to assume a process-based approach, such as that of creative cognition, to define a process that reflects one aspect of creative thinking in a specific domain; then, one might use cognitive neuroscience methods to assess the features of this process in terms of cognitive and neural functions. Such studies should contribute to unraveling the fascinating complexity that is central to creativity.

Research: Phenomenology

B Nelson, University of Melbourne, VIC, Australia

© 2011 Elsevier Inc. All rights reserved.

Glossary

Flow A mental state in which a person is fully immersed in an activity, associated with a feeling of energized focus, full involvement, success in the process of the activity, and feelings of pleasure.

Peak experiences Moments of highest happiness and fulfillment.

Phenomenological philosophy A branch of philosophy that concentrates on the study of consciousness and objects of direct experience.

Qualitative research A research approach applied in many disciplines that explores and tries to understand people's beliefs, experiences, attitudes, behavior, and interactions. It generates nonnumerical data. The best-known qualitative methods of inquiry include in-depth interviews, focus groups, documentary analysis, and participant observation.

Introduction

This article addresses phenomenological research into creativity. The phenomenological approach is a form of qualitative enquiry that emphasizes *experiential, lived* aspects of a particular construct – that is, how the phenomenon is experienced *at the time that it occurs*, rather than what is thought about this experience or the meaning ascribed to it subsequently. For this reason, phenomenology is sometimes described as dealing with 'prereflective' experience. It is a research approach well-suited to analyzing the process and experience of creativity, as opposed to the creative product or the creative person. These aspects of creativity (the process and experience of creativity) have not been adequately studied to date. As Mihali Csikszentmihalyi and Jacob Getzels (1971) write: "Despite much recent research on creativity, perhaps the most critical aspect of the problem has eluded systematic inquiry: the process of creative production itself" (p. 47).

Below, a selective review of phenomenological studies of creativity is presented. These studies have tended to focus on *artistic* creativity, as opposed to other forms of creativity, and this is reflected in the article. When describing phenomenological findings, indeed qualitative findings more generally, it is often necessary to adopt the language and terminology of the researcher in order to do justice to the subtlety of what they are attempting to capture descriptively.

Phenomenological Studies of Creativity

The findings of an early phenomenological study of the creative process have been repeated and echoed in a number of subsequent studies. This study therefore provides a useful starting point. Charlotte Doyle (1976) offers a phenomenological account of the artistic creative process, the findings of which are largely supported by a later empirical study by the same author with five recognized fiction writers. She draws attention to the variety – and the contradictory and sometimes *paradoxical* nature – of statements made by creators and theorists about creativity. Doyle focuses on the temporal unfolding of the

creative process and uses this dimension of time to contrast the differing views on creativity. According to Doyle's account, the beginning of the creative process is marked by *a sudden trigger or a vague intuition that something is available to work on* – either way, it begins with a sense of *direction*. However, at this point, the final form or nature of the artwork is not clear, it is not yet articulated. Rather, the artist needs to "*think(s) through his medium*" (p. 115; italics in original). There is a sense in which the direction of the artwork evolves through interaction with the medium. In the adoption of the medium as a means of 'thinking,' certain "so-called logical distinctions disappear, for example, the distinction between intellect and emotion" (p. 116). In order to be able to adopt the medium as a means of thinking, the artist needs to have developed a certain degree of skill or control over her craft. The development and clarification of the original germ by thinking in the medium does not occur instantly – rather, the artist experiments until she experiences a sense of *recognition*, a sense of having made manifest the original inspiration of the piece.

Rather than there being a single moment of discovery, a sudden insight or recognition that provides resolution, Doyle (1976) describes "... extended periods of work punctuated by surprises large and small" (p. 119). Affective elements may vary according to this fitful unfolding of the process: despair and loneliness may accompany the periods of searching, whereas satisfaction and pleasure may be brought on by the sense of discovery. At some stage in this process, Doyle asserts that a "period of total centration" (p. 119) takes over. She describes this as involving a sense that the work is 'creating itself' (e.g., the melodies flow without forcing, the characters seem to have a life of their own, and so on), the artist is totally absorbed in and directed toward the work, he is no longer self-conscious, and experiences a sense of freedom, spontaneity, and joy (cf. the construct of 'flow,' described below). Although creative episodes can reach a climactic conclusion in periods of centration, these periods typically come and go in waves.

The final stage of creative work is driven by attempting to capture the 'truth' or meaning that the artwork is dealing with as well as one can. This is often characterized by a sense of commitment and determination, which has helped the artist

survive the awkward attempts at 'thinking through the medium' and the multiple cycles of centration and failure. The act of showing the work to an audience is an "affirmation of (the artist's) relatedness to human society" (p. 123).

Doyle (1976) argues that this account of the experiential aspects of creativity as it unfolds through time helps resolve the paradoxes in various other accounts of creativity. From this perspective, Doyle is able to assert:

The creative process involves freedom and spontaneity. The creative process demands discipline and concentration, and a commitment to work. It involves the primitive and emotional, intelligence and thought; it calls upon fantasy and inventiveness, a willingness to deviate from what is; it demands honesty and a commitment to truth. It is an expression of self and it cannot take place without forgetting the self; it is a joy and a terror; it is its own reward; it requires encouragement and understanding from others. (p. 123)

These statements are not contradictory when the different experiential states associated with the temporal unfolding of the creative process are considered. Her nonlinear model is a challenge to more traditional 'stage models' of creativity, such as Wallas' (1926) classic model of four stages (preparation, incubation, illumination, verification) unfolding sequentially over time.

Sophia Reinders (1992) investigated the phenomenology of artistic creativity through open-ended interviews with three internationally recognized artists from the diverse fields of choreography, painting, and musical composition. The participants were asked to describe their experience of creating a recent or current artwork, particularly the way in which they perceived and solved problems in the creative process.

The study's findings were as follows. The artist assumes an artistic perspective toward certain aspects of his 'life-world,' or experience. This gives rise to a sense of lack, which engages his artistic desire to produce an artwork that will fulfill or 'speak to' this felt lack. The artist has a vague, intuitive sense of the artistic object and the direction in which he should project his artistic pursuit in order to fulfill the sense of lack. Within this tension between desire based on a felt lack and an intuited artistic object, the artist engages in a process of exploration – he engages in repeated trials and variations in order to come closer to the intuited artistic object. This exploratory process also clarifies the artist's implicit guiding idea. The artist actively manipulates his artistic material as a means of exploring its expressive possibilities with regards to his global intuition of the artistic object he wishes to create. The exploratory search is informed by what Reinders terms the "demands of the artistic object." In this exploratory process the artist 'recognizes' artistic constellations or 'units' that bring the work closer to realizing the intuited intentional object. The spontaneous discovery of fulfilling artistic structures is felt to be beyond the artist's control.

The exploratory process is characterized by a number of seemingly paradoxical attitudes. First, the artist adopts an attitude of 'purposive-playfulness,' which refers to the active manipulation of his artistic materials in a highly playful, probing manner in order to realize his intentional object. The attitude of 'circumscribed indeterminacy' is also assumed. This refers to holding at bay the knowledge derived from previous artistic experiences and trusting that his artistic intuition and artistic perception will recognize emerging artistic

configurations that speak to the intentional object. The artist is being both active and receptive: active in the sense that his actions are informed by his artistic intuition of the intentional object and receptive in the sense of remaining sensitive to the emerging artistic configurations. Reinders (1992) writes: "... the artist lives his or her experience paradoxically as bringing forth and attending to the emergence of the artistic object" (p. 6). Another paradox at work is 'distant-engagement' – that is, an alternation between immersion in the manipulation of material and distancing oneself, looking at the emerging artistic structures from the perspective of the audience, in order to clarify the overall structure or gestalt of the object.

As the artistic structures for the intentional object continue to develop and become more complex, the sense of recognition becomes stronger. This is experienced as "a global bodily felt sense of meaning" (p. 67). A sense of completion is attained as the artist gradually forms the configuration of artistic tensions into "a balanced totality of artistic significance" (p. 68). Again, the sense of completion is felt on a physical level. The completion also has a paradoxical element to it, because although the artist 'feels' the work to be completed, the meaning of the artistic object remains ambiguous and open to change. The temporality of the process is characterized by a nonlinear but rhythmic progression. For example, phases of direct involvement with the artistic material may alternate with periods in which the artist's conscious attention is directed to some unrelated pursuit. An attitude of risk-taking characterizes the overall process – in the bracketing of previous experiential knowledge, the maintenance of an open-ended attitude, and engaging in a process of exploration without knowing exactly what is being searched for.

Central to Reinders' (1992) account of the experience of artistic creativity are concepts of desire, exploration, discovery, intuitive recognition, and paradox. The sense of lack, exploration and the dialogue between the artist and her material concur with Ó Cluanáin's (1979, 1981, 1987) series of non empirical qualitative studies of the phenomenology of creating and appreciating art. After reviewing the writings of four phenomenological philosophers and two contemporary psychologists on the phenomenology of art and aesthetics, Ó Cluanáin (1987) offers several general conclusions. First, he writes of artists discovering a 'special world' in the immediate, 'given world': "This 'special world' has been present in the 'given world' as a potential of which we have had glimpses on occasion, but also of which we have perceived but little, on account of preoccupation with mundane things" (p. 104). This discovery is achieved through utter respect for the 'otherness' of the medium. As in Reinders' (1992) findings, Ó Cluanáin sees the creative process as requiring a novel, exploratory encounter with the medium: "Presumption of familiarity with media is not allowed" (p. 105). This encounter does not involve a sense of control over the medium, but rather an "accommodation to its character" (p. 104). Ó Cluanáin observes that this aspect of the creative process, in addition to requiring humility, involves "... a decentration of one's subjectivity, which is an edification of one's subjectivity" (p. 104). Although different in nature, this dynamic relating to the artist's subjectivity echoes Reinders' (1992) emphasis on the paradoxical elements of the creative process. Another point of contact between the studies is the motivating force of

desire borne of a sense of lack: while Reinders (1992) writes of “an artistic perspective which gives rise to the experience of a lack” (p. 5), Ó Cluanáin (1987) writes of an “... unease in the artist, a yearning to resolve toward completeness the experienced fragment of a vision” (p. 105).

The themes in Reinders’ (1992) and Ó Cluanáin’s (1987) findings of not being ‘in control,’ of discovery, and of the role of intuition are also apparent in Amedeo Giorgi’s (1984) phenomenological study of the artistic process. This study was based around descriptions provided by two visual artists. The phenomenological structure that Giorgi found to be common to both artists was described as follows:

In creating a work of art, a person must pursue the achievement of the artwork in an open-ended way that constantly risks failure. The risk of failure is defined by the constraints of the task demands which are simultaneously precise, yet incomplete, and understood by the artist initially primarily through their excesses (e.g., literalness or surrealism). As the work progresses, specific positive guidelines also emerge, but still final closure is held off until the last possible moment. Conscious and unconscious processes intertwine constantly as do personal and artistic perspectives. In general, what the artist is aware of are the general aim and demands, and what he or she is least aware of, it at all, are the specific achievements that are accomplished. The obscurities in the process are due largely to the fact that artists are guided by feelings rather than knowledge, and to the fact that artworks are as much the result of spontaneous actions of the artist body as planned activities. (p. 26)

Sheree Conrad (1990) takes a somewhat different tack in her phenomenological analysis of artistic creativity. Rather than approaching the phenomenon through accounts provided by artists, Conrad’s investigation is based on her own experience of artistic activity (specifically, fiction writing), in the tradition of philosophical phenomenology. Conrad justifies this introspective approach by drawing on the philosopher Husserl’s (1913/1931) notion that the logic of any human experience is, in principle, available to any human subject.

Conrad’s (1990) description of the fiction-writing process starts with a sense that engaging in the production of the artwork is not ‘optional’ – that there is an imperative driving the artist. This imperative is the result of the artist sensing that the artwork “already exists” (p. 111). Indeed, the process is characterized by trying to *discover* the nature and character of the artwork. This is achieved by navigating a dynamic between recognition, which is associated with a sense of excitement, and sensing that the artistic production has strayed from what it ‘should’ be. The ‘discovery’ of the artwork occurs through interaction with the medium, as opposed to being a pre-formulated image that the artist is trying to capture through manipulation of the medium: “The writer has to find out what the story is by writing it” (p. 112). The language of intuition rather than critical mental processes is used to describe this process: “The writer feels toward it, knowing quite clearly what isn’t it, yet still unable to see what is” (p. 112). In fact, conscious, critical processes (referred to as “the voice of invention, of conscious creation” (p. 112)) are presented as interfering with the intuitive grasping of the artwork. In this sense, the artist is not so much in control of the creation as coaxing it along, letting it emerge: “If I push too hard, the thing evaporates” (p. 113). When the artist emerges from the trance-like

state of ‘discovering’ the artwork, she can be exhausted and disoriented, and experience a sense of detachment from her surroundings. The process of looking over the work is characterized by a twofold reaction: surprised certainty that this is as the artwork *should* be, that ‘it’ has been captured, and rejection of elements of the piece on the basis that they do not accurately capture the character of the artwork (“(they) are wrong, not it, bits that shatter the re-unfolding dream or flatten and muddy it” (p. 113)).

The writer’s twofold reaction is paralleled by the double reaction of the reader – the reader “... responds to a story with either shocked recognition – ‘Yes. That’s it, exactly’ – or with scorn – ‘That’s a lie, that’s not it at all’” (p. 113). For Conrad (1990), this ‘double’ recognition on both the part of the artist and the audience is testament to the fact that artwork is concerned with revealing meanings that are hidden, but common, to all human experience, rather than merely reflecting the idiosyncrasies of the creator. Drawing on tenets of philosophical phenomenology, she writes: “Because the logic or meaning of experience is invariant across time and culture, and directly available to any subject independently of theoretical constructs, the reader, no less than the writer, can see places where the story, the text, departs from the necessary logic of the human experience it presents. ... The present analysis sees the *sine qua non* of art as truth, not novelty, that of artistic activity composition, rather than creation” (p. 115). (The emphasis on artwork as revealing ‘truth’ rather than being concerned with innovation or the artist’s individual psychology is of interest with regards to cross-cultural perspectives on creativity. Ironically, considering Conrad is writing from the decidedly Western perspective of Continental phenomenology, her account of experiential aspects of the creative process is consistent with central elements of Lubart’s (1999) summary of Eastern views on creativity – particularly the notion of creativity as a process of repeating or rehearsing a ‘known’ truth through skilled composition rather than inspired novelty, which is more characteristic of Western views on the construct.)

Clearly, Conrad’s (1990) account displays significant overlap with the other phenomenological accounts of creativity outlined above, particularly with Reinders’ (1992) and Giorgi’s (1984) sense of the artist responding to the ‘demands’ of the artwork (Conrad in fact adopts this term at one point: “The artwork, the meaning grasped, makes its own demands, suggests its own proper or optimal instantiation ...” (p. 115)). The sense of the artist not being in ‘control’ of the process, the prominent role of intuitive, emotional processes, and the sense of discovery through interaction with the medium are also points of contact with the other accounts. Particularly prominent in Conrad’s account is the interfering role of conscious, critical mental processes.

Nardone (1996) applied a phenomenological analysis to the experience of improvisation in music. She conducted open-ended interviews with three jazz musicians recognized as proficient in performing and teaching musical improvisation. Her analysis yielded two phenomenological structures: one emphasizing the psychological experience of improvisation and the other the musical context in which improvisation takes place. The first of these structures was composed of eight elements: ensuring spontaneity while yielding to it; being present and

not present to musical processes; exploring familiar and unfamiliar musical terrain; drawing from a corporeal and incorporeal source of musical inspirations; attending moment to moment to temporality; having trust and confidence in oneself and musical others in musical risk taking; being sustained by and sustained by the musical other; and extending toward the listening other in musical risk-taking. The second structure was composed of three elements: perceiving temporality as altered; identifying the narrative context as grounding and providing a structure for concretization of musical expression; and recognizing the existing sociocultural context as liberating and transforming. Dialectical paradoxes play a prominent role, as in Reinders' findings, particularly in the structure relating to the psychological experience of improvisation. As with the other studies, "non-rational intelligence" (p. 4) is also seen as primary in the creative process, although Nardone emphasizes the role of the body in these nonrational processes.

Barnaby Nelson (2009) investigated the phenomenology of artistic creativity through semi-structured interviews with 11 artists. The findings consisted of 19 interlinked elements, with three dynamics operating within these elements: a dynamic between intuition and analysis, between a sense of union and division, and between freedom and constraint, which is consistent with the findings of the studies reviewed above. A questionnaire, the Experience of Creativity Questionnaire (ECQ), was developed and validated based on these findings. This questionnaire was applied to a sample of 100 artists to investigate the relationship between aspects of creative experience and personality and psychopathological features. The study revealed a strong relationship between schizotypy, an aspect of personality related to psychotic-like experience or psychotic vulnerability, and a range of aspects of creative experience. This indicates that people with schizotypal tendencies may be particularly suited or driven to creative activity, which is consistent with biographical studies of eminent creators through history. This study illustrates the useful integration that can be achieved between qualitative and quantitative studies of creativity.

Phenomenological Studies of Constructs Related to Creativity

The phenomenology of several constructs related to creativity have also been investigated by a number of researchers, at times using a stricter phenomenological method, as described above, and at times using a more general qualitative approach. Examples include Csikszentmihalyi's (1975, 1990b, 1996) construct of 'flow' and the notion of peak experiences, most commonly associated with the work of Abraham Maslow (1968, 1971). The construct of 'flow' was developed through interviews with people such as chess players, rock climbers, dancers, and composers, who seemed to be engaged in activities that they enjoyed but for which they were not rewarded with money or fame. Csikszentmihalyi (1996) outlined the quality of experience that kept people motivated to pursue such activities. He suggests that this experience, referred to as 'flow,' is composed of nine main elements: there are clear goals every step of the way; there is immediate feedback to one's actions; there is a balance between challenges and skills;

action and awareness are merged; distractions are excluded from consciousness; there is no worry of failure; self-consciousness disappears; the sense of time becomes distorted; and the activity becomes autotelic.

Some of these elements of 'flow' are apparent in the accounts of creative experience outlined above. Csikszentmihalyi's (1996) own interview-based study of 91 individuals recognized for their creative achievements indicated that flow experiences play a prominent role in the creative process. He proposes that the pleasure or joy characteristic of flow-type experience is an intrinsic 'reward' for the creative process, thus motivating creative activity. Drawing on evolutionary principles, he suggests that human beings are 'programmed' for creativity through this mechanism.

Susan Perry (1998) examined flow experiences in 62 regularly publishing writers. She found that writers identified flow experiences as central to their work and that they often actively constructed conditions that facilitated entry into this state. Five key conditions were identified for entry into the flow state: personality factors, including emotional resilience, openness to experience, absorption, and looseness of boundaries in thinking; a combination of motivational factors; physiological and psychological relaxation; becoming engaged with and focusing on the work; and maintaining a balance between the opposites of willing/not willing, thinking/not thinking, and audience awareness/unawareness.

'Peak experiences' are defined as moments of highest happiness and fulfillment. Maslow (1971) and Laski (1961) provided accounts of such experiences in religious and non-religious contexts, such as during childbirth or athletic events, and while enjoying music, nature, or dancing. It has been argued that heightened creativity is a characteristic of peak experiences and that creative work is a common trigger of peak experience. Maslow (1962) stated that peak experiences release a person "for greater creativity, spontaneity, expressiveness, idiosyncrasy" (p. 101). Maslow (1971) also asserted that it is the power to evoke peak experiences that distinguishes great art from the inconsequential. Rollo May (1959) stated that ecstasy, the central feature of peak experiences, describes a level of consciousness that occurs during the creative act.

Moncrieff (1989) examined aesthetic appreciation, referred to as 'aesthetic consciousness,' but not with particular reference to peak experiences. Although Moncrieff's findings indicated a variety of features of aesthetic consciousness, involving personhood, creativeness, performance, appreciation, symbolization, and expression, his discussion focused on 'oneness,' which he found to be a central feature of aesthetic consciousness. The experience of 'oneness' involves a structural wholeness, in the sense of a perception of a constant series of relations between the various elements of the experience (i.e., an enhanced sense of inter-connectedness). It also involves a loss of distinction between the experiencer and the experienced, between the inner and outer worlds; it can be experienced as a transitional moment; the particular experience can symbolize the more general "rhythms of life" (p. 250); it can involve a sense of expansion of personal presence; there can be a flowing quality to the experience; and language can seem to be an inadequate means of describing the experience. A central feature of the experience is contact between the individual ego or persona and the Self in the Jungian sense of the unifying and

identity-making center that subtends the ego. This can have the effect of leaving the individual feeling more deeply engaged with themselves and the world.

Recurrent Themes

A number of recurrent or common themes are evident in the phenomenological studies of creativity and related constructs outlined above. These themes include motivation to produce creative work (based on factors such as a felt sense of lack, the sense of importance of or desire for expression, etc.) within the context of having developed appropriate skills; 'exploration' of possibilities, often including trials and variations, and the sense of recognition of emerging structures in the creation; responding to the 'demands' of the piece being created; the prominent role of intuition; interaction between the creator and the medium; lack of a sense of control over the unfolding process; and the role of affective pleasure and flow-type experiences. Studies of aesthetic awareness or consciousness have indicated that this construct can involve a transition in experience of the self-world relationship, particularly involving the dissolution of boundaries and the experience of 'oneness.' This experience is also evident in studies that investigate creativity more directly.

Concluding Remarks

This article has illustrated how phenomenological studies of creativity can be a useful way of elucidating the subtleties and details of creativity, particularly with regards to the creative process and experience, as opposed to the creative person or product. As Louis Sass has remarked:

... (I)n the absence of such studies, there is a sense in which we literally do not know what we are talking about (or looking at, or counting up in our research studies) when we speak of creativity, creative psychological processes, or certain types of psychopathology. (2000–2001: 42)

A challenge for the field is to integrate the findings from phenomenological studies with other areas of creativity

research in order to build multi-faceted models that capture the complexity of the construct. The detailed descriptions provided in phenomenological studies may shed light on research into such areas as personality, affective, and motivational aspects of creativity. For example, questions might be asked such as: Does the experience of the creative process contribute to our understanding of why people with particular personality characteristics or psychopathological vulnerabilities are attracted to creative work? Do affective components of creative experience shed light on some of the contradictory findings in the creativity-affect literature? How do experiential aspects of the creative process relate to motivational factors driving creative activity?

Glossary

Effectiveness of creative problem solving The number of solutions receiving a rating of likely or very likely to achieve an objective.

Efficiency of creative problem solving The number of effective solutions divided by the total number of solutions.

Flexibility of creative problem solving The number of generated solutions in different categories.

Fluency of creative problem solving The number of solutions not previously generated.

Gordon's synectics The motto of which is 'making the strange familiar, and making the familiar strange.'

Making the strange familiar is critical thinking involving data gathering, analysis, synthesis, and evaluation to connect prior knowledge with the present problem, define the problem, and evaluate the solution. Making the familiar strange is creative thinking embracing breaking old associations, incorporating imagery, analogy, and broad search to produce new ideas or products.

Quasi-experimental designs The experimental designs that no process of randomization was conducted by the assignment of participants either to experimental or to control group.

Real experimental designs The experimental designs that demand a process of randomization by the

assignment of participants either to experimental or to control group.

Single-case experimental design This kind of design has two basic forms, the reversal design and the multiple-baseline design. The reversal design contains at least three phases: the first baseline phase, a treatment phase, and the second baseline phase. The purpose of reversal of treatment phase to baseline phase is to ascertain that alternative interpretations of the treatment effect are precluded. The multiple-baseline design contains at least two baselines across participants, behaviors, or situations. The treatment is introduced to the second baseline after it has shown effect on the first one.

Structural equation modeling analysis In such an analysis, a common factor among the correlated independent and dependent variables is extracted and labeled as independent latent variable and dependent latent variable respectively. The latent variables cannot be measured but can be represented by observed variables. A structural equation model can contain multiple independent latent and dependent variables. A gamma coefficient depicts the effect of independent latent variable on the dependent latent variable. The error term represents the percentage of variances of dependent latent variable that cannot be explained by the independent latent variable(s).

The understanding that the experience of failure whilst knowing its cause is worthier than that of success without knowing its reason is an important guideline in scientific research. Researchers employing quantitative research methods should keep reliability and validity of measurement of creativity in mind to eliminate the measurement errors as much as possible; otherwise it will be difficult to build up a replicable body of knowledge in the field of creativity.

This article describes the quantitative methods used in empirical research into creativity. Quantitative research methods include experimental studies, correlation methods, and meta-analysis. Experimental studies aim to identify the controlling variables relevant to creativity by means of experimental designs. Correlation studies attempt to find relationships between creative behaviors and various variables, such as personality characteristics and environmental settings under which the creativity of individuals is encouraged and facilitated.

Experimental Studies

The purpose of experimental research is to build replicable findings leading to the establishment of a scientific body of

knowledge in creativity. In 1996 Runco and Sakamoto made a thorough review of experimental studies of creativity that included the manipulation of relevant variables in creativity. A prerequisite of an experimental study is the operational definition of the independent as well as the dependent variables. In 1996 Runco defined creativity in terms of transformation, discretion, and intentions and tried to get close to the mechanism of the creative process. To this point the mechanism that underlies creative thinking is still unclear. Ma conducted a meta-analysis in 2009 and tried to define the process of creativity as "the ability to reorganize the available knowledge, information, cues, facts and/or skills in a person's reservoir to generate new ideas or useful solutions." Ma arrived at this conclusion partly in accordance with the evidence derived from the meta-analysis and partly based on the concepts and series of experimental studies (process-based measures of creative problem solving skills: I-V) made by Mumford and his colleagues. Many of us have had the experience of incubation, that is, if we confront a problem and find that we cannot solve it after working hard on it then we take a break or do something else, then we can suddenly find the solution. The question whether the process of incubation is a mechanism of reorganization of knowledge should be addressed in future research.

Between Groups Experimental Designs

Real experimental designs

Experimental studies demand a process of randomization by the assignment of participants either to an experimental or to a control group. The definition of randomization is that every member of the target population must have an equal chance of being chosen as an experimental participant. The purpose of randomization is to ensure that the unknown background variables of the experimental and control groups are equal before the implementation of treatment. In 1993 Fontenot conducted an experiment to examine the effectiveness of a training program based on the Osborn–Parnes Creative Problem-Solving Model. Sixty-two business people were drawn from six different businesses as participants and were randomly assigned to either the experimental or control group. The dependent variables were operationally defined as: (a) fluency in data finding or information retrieving (the number of different data or information generated); (b) fluency in problem finding (the number of alternate problem statements produced); (c) flexibility in problem finding (the number of categories created by the generated alternate problem statements); and (d) quality of the problem statement (the complexity of each group's final problem statement judged by two experts in terms of the degree to which the needs and motives of all those involved in the problematic situation including the owner, goal, and constraints identified in the final problem statement were satisfied). The results demonstrated that the training program was effective on the four dependent variables. The statistical significances reached at least at 0.10 level when using a one-tailed *t* test for independent samples.

Quasi-experimental designs

It is difficult to utilize random sampling in the natural settings such as schools, so there is usually an arbitrary assignment of one class in a school as an experimental group and the other as a control group. The internal validity of quasi-experimental designs is often threatened, because differences may exist before the experimental treatment is implemented; hence alternative interpretations of the results of the experiment cannot be excluded.

In 1996 Gendrop described his research as a quasi-experimental study. After taking pretests, which contained the TTCT, the Gordon Creative Problem Solving Test (GCPST), and the Watson–Glaser Appraisal of Critical Thinking (WGACT), 51 participants were randomly assigned to an experimental group and 46 to a control group. The fact that all of the mean scores of the control group in the creativity tests were higher than those of the experimental group cast the process of randomization in doubt. If the randomization process occurred before the pretesting, it would become a real experimental design. The treatment encompassed 4 h of reading a self-paced text 'The New Art of the Possible: The Basic Course in Synectics' and completing exercises, and 6 h of workshop, which consisted of interactive peer experience in small groups, a short quiz, and practices. The participants in the experimental group underwent the treatment before taking the posttests in creativity while those of the control group took the posttests before undergoing the treatment. The key treatment

was the use of Gordon's synectics, the motto of which is 'making the strange familiar, and making the familiar strange.' Making the strange familiar is critical thinking involving data gathering, analysis, synthesis, and evaluation to connect prior knowledge with the present problem, define the problem, and evaluate the solution. Making the familiar strange is a form of creative thinking which embraces the breaking of old associations, incorporating imagery, analogy, and broad search to produce new ideas or products. The results of Gendrop's study exhibited that pretest–posttest differences between the means in fluency, flexibility, and originality on the TTCT and on the GCPST were significantly larger for the experimental group than for the control group.

Observational method

This method puts two different groups under conditions of laboratory control and observes whether differences between groups exist in the dependent variable. Suppose that we want to investigate whether the thinking process of highly creative people differs from that of less creative ones, we may employ a meta-cognitive approach. After a creativity test is administered and scored, the participants can be divided into a highly creative group and a less creative group on the basis of whether their creativity scores are above $M + 0.5$ standard deviation (SD) or below $M - 0.5$ SD. Both groups undergo the same treatment, that is, during the time that they are solving problems, they are asked to speak what they are thinking aloud. The experiment is carried out individually. Their responses are audio-visually recorded, verbatim transcribed, and coded in accordance with the following categories:

1. redefining the problem;
2. retrieving information from their own reservoirs of knowledge, skills, experiences, and cues, etc.
3. reorganizing the knowledge and formulating a strategy of problem solving;
4. trying the solution;
5. evaluating the appropriateness of the solution;
6. finishing the problem solving or returning to the previous steps;
7. others that cannot be classified into the above steps; such as incubation including taking a break.

This kind of experimental study is a hypothesis-formulating exploration, not a hypothesis-testing study, because the difference that exists in the process of problem solving between the highly and less creative groups is unknown. A hypothesis of the process of creative problem solving can be formulated only after a difference is found by comparison. After that, a randomized real experimental design must be conducted to test the formulated hypothesis. Differing from the aptitude or intelligence tests, the participants in a creative problem solving test should be allowed to take breaks during the test session so that possible incubation may occur.

Single-Case Experimental Designs

Single-case experimental design, within-subject design, and single-subject design are synonyms. This kind of design has two basic forms, the reversal design and the multiple-baseline

design. The reversal design contains at least three phases: the first baseline phase, a treatment phase, and the second baseline phase. The purpose of the reversal of the treatment phase to baseline phase is to ascertain that alternative interpretations of the treatment effect are precluded. One of the important characteristics of single-case experimental design is that both the independent as well as the dependent variables are operationally defined. An experimental study was successfully carried out by Glover and Gary in 1976 to stimulate the creativity of the four basic components of creativity proposed by Torrance: fluency, flexibility, elaboration, and originality.

In a single-case experimental design, authors usually judge the effectiveness of treatment according to their intuition. It would be scientifically more acceptable if the effectiveness could be expressed in terms of percentage of data points exceeding the median of baseline phase (PEM) scores and judged in accordance with the criterion set by Scruggs and his colleagues in 1986, which categorized scores equal to or larger than 0.90 as highly effective, equal to or larger than 0.70 but less than 0.90 as moderately effective, and less than 0.70 as questionable or not effective. 'Questionable' and 'not effective' are combined together as it is hard to distinguish between them visually.

The data points in a single-case experimental design usually have autocorrelation and hence preclude the use of parametric statistics to test the significance of the difference of data points between the baseline- and the treatment-phase due to violation of one of the three basic assumptions of the parametric statistics, that is, the independence of the distribution of residuals. The PEM approach is a nonparametric statistic and therefore suitable for this purpose.

Calculation of PEM scores

A PEM score is calculated from the data points of a pair of baseline-treatment phases. To compute the PEM scores, one needs only to draw a horizontal median line in the baseline phase. This horizontal median line will hit the median when the number of data points in the baseline phase is odd, and go between the two middle points if the number of data points is even. This median line will stretch out horizontally to the treatment phase. Then the percentage of data points of treatment phase above the median line may be calculated.

Figure 1 is the simulation of the results of the experiment carried out by Glover and Gary in 1976. The treatment in Glover and Gary's study was reinforcement with edible foods and 10 min of recess as reinforcers. Students were instructed to list all the possible unusual uses they could think of for an inanimate object listed on the board in each session. The four components of creativity were defined as: (a) fluency, number of different responses; (b) flexibility, number of verb forms; (c) elaboration, number of words per response; and (d) originality, statistical infrequency of verb forms. In a calculation of their results using the PEM method, the PEM scores of the effect of reinforcement on all of the four components of creativity were 1.0 (highly effective). In order to illustrate the method of calculation of the PEM scores, a new set of data is artificially generated and demonstrated in Figure 1. After 1 week of baseline measurements, the reinforcement was contingent on the fluency. The median of the baseline phase is 10. Hence a horizontal line of the median is drawn and extended to the treatment phase. Four points in the treatment

phase exceed the median line of the baseline phase. $PEM\ score = 4/5 = 0.80$. Likewise, the PEM score is 0.80, 1.0, and 0.50 for flexibility, elaboration, and originality, respectively. According to the criterion set by Scruggs and his colleagues, the treatment with reinforcement on fluency and flexibility is moderately effective, for elaboration it is highly effective, and for originality it is questionably or not effective.

The illustrative Figure 1 is a multiple-baseline design; however, a reversal design is simultaneously applied for the dependent variables except for originality (the lowest panel). This kind of research cannot only be used to test the effect of reinforcement on the single components of creativity but also to test the generalization of the learned industriousness theory proposed by Eisenberger in 1992, according to which, individuals learn which aspects of creativity are rewarded, resulting in the motivation to perform appropriately.

Correlation Methods

Cross-Sectional Study

The method of cross-sectional study is a kind of correlation method that administers questionnaires or testing to collect data at a time point to produce a correlation matrix, based on which different statistical analyses, such as regression, univariate analysis, multivariate analysis, structural equation modeling (SEM), etc., can be applied to test various hypotheses. Reuter and his colleagues in 2005 recruited 48 undergraduate students as participants and employed a laboratory technique to analyze testosterone from saliva samples of participants and then administered testing instruments to assess personality and creativity. Creativity was assessed by the creativity subscale 'inventiveness' of the Berlin Intelligence Structure Test. Scores of figural, verbal, numeric, and total creativity were calculated for each participant. For personality, two instruments were implemented: (a) Eysenck's psychoticism dimension which measures aggression, antisocial behavior, emotional coldness, impulsivity, hard-heartedness, and insensitivity; and (b) the SEEK dimension of Panksepp's new Affective Neuroscience Personality Scales which measures feelings of curiosity, the drive to explore, and striving for solutions. The results of the study by Reuter et al., showed that there were significant correlations between SEEK and testosterone and between SEEK and all four scores of creativity. However, no significant correlation was found between testosterone and creativity scores.

Cross-sectional studies on developmental trend in creativity

Developmental trends in creativity can also be investigated by means of cross-sectional studies. Charles and Runco in 2000–01 drew 102 children from the third, fourth, and fifth grades from two elementary schools to investigate developmental trends in divergent and evaluative thinking. The participants were asked to name instances of round things and things that make a noise. Contrary to the findings in the study conducted by Torrance in 1968, where a slump was found in the fourth grade in the developmental trends, from the third to fifth grade on fluency, flexibility, and originality, Charles and Runco found that children in the fourth grade scored higher than third- and fifth-grade children on fluency, flexibility, and originality. Whereas the method used by Torrance in 1968 was

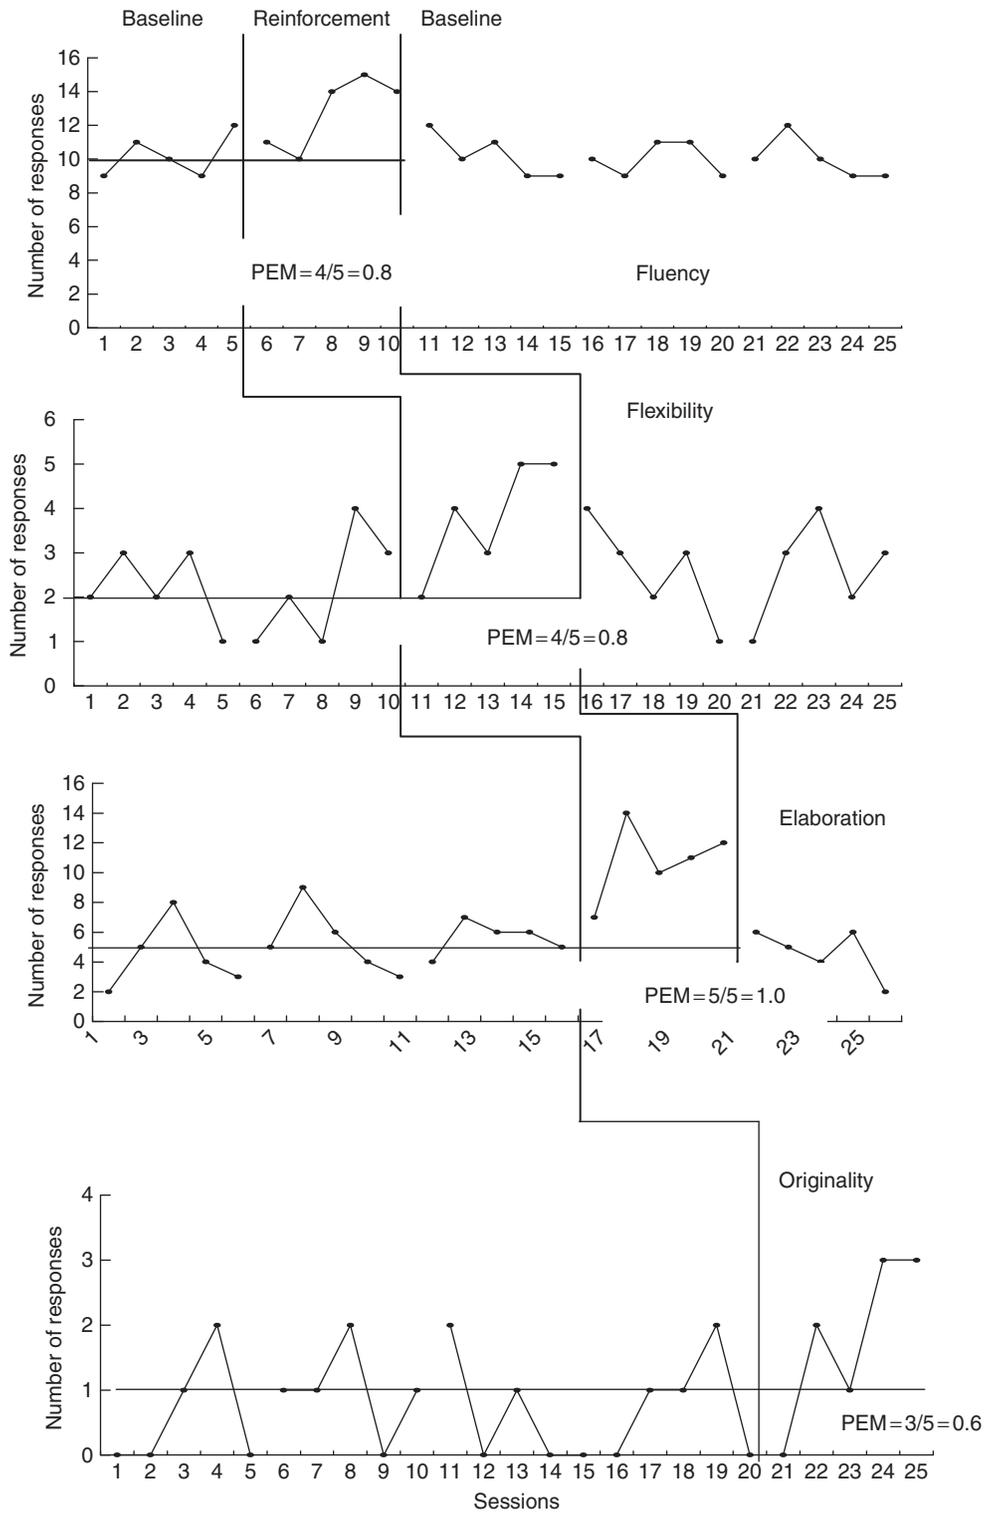

Figure 1 Demonstration of the calculation of PEM scores with artificially generated data.

longitudinal, the one employed by Charles and Runco was cross-sectional; further research is needed using the same reliable and valid measurement instrument, the same research method, and extension of grade span (from first grade to adult age) to portray the developmental growth curve of creativity.

The major difficulty in conducting a longitudinal study is the high attrition rate of the number of participants during the tracking, and a major one in conducting a cross-sectional study is to be able to collect data of large scale representative samples of grades extending from first-grade children to adult.

Longitudinal Studies

Predictive validity studies

Can the test scores of creativity be used to predict creative achievements in the future? In 1972 Torrance reviewed some longitudinal studies and found that the results were positive. In almost all of the studies, no matter whether short-range (1 week to 9 months) or long-range, the Torrance Tests of Creative Thinking (TTCT) were administered to the participants in the first wave of a predictive validity study. Using the median creativity score as the dividing line, the participants were divided into highly and less creative groups, then the creative achievements were measured at the second wave of the study at a later time. For example, in the study conducted by Torrance and Hansen in 1965, after taking a battery of TTCT, six highly creative and six of the least creative basic business teachers were selected for detailed classroom observation during five different class sessions over a 4-month period. The verbatim record made during the observation was analyzed in terms of divergent questions asked by the teachers. The highly creative teachers were found to significantly outperform the less creative teachers. For the long-range longitudinal studies, the variables selected as the indexes of creative achievement were such as writing a poem, story, song, or play; writing a book; publishing scientific papers; inventing patentable devices, receiving literary awards or prizes for creative writing, musical composition, art, etc.; and receiving research grants for original proposals. In a longitudinal study tracking precocious youths (top 1%) over 20 years conducted by Wai, Lubinski, and Benbow in 2005, based on the scores on the Scholastic Aptitude Test-Mathematics (SAT-M) of the participants at age 13, the top (Q4) and bottom (Q1) quartiles of participants were identified for a questionnaire survey at age 33. The results showed that the percentage of produced patents was 7.5% for the Q4 and 3.8% for the Q1. The effect size difference computed with an arcsine transformation, $h = 0.18$, was significant at 0.01 level. The results of Wai and his colleagues' study supported Huber's conclusion that the number of patents is an objective index of inventive and scientific achievement. In 2005 Cramond and his colleagues summarized the 40-year follow-up study conducted by Torrance, who administered various batteries of the TTCT, intelligence and achievement tests, and sociometric questionnaires each year from 1958 through 1964. In 1980 and 1998 Torrance carried out a second and third wave data collection of his longitudinal studies. The valid number of located participants in the 1998 follow-up was 80. Cramond and his colleagues employed a structural equation modeling analysis to investigate the predictive validity of TTCT scores from Torrance's longitudinal study. The observed variables for the creativity latent variable were scores of fluency, flexibility, originality, and elaboration of the figural TTCT. The observed variables for the latent variable 'creative achievement' were the 'quantity' and 'quality' of adult creative achievements, which were generated by ratings of three experts who judged the creativeness and importance of participants' creative achievement based on the information reported by the participants in the follow-up questionnaires. The results of the study of Cramond and his colleagues demonstrated that the TTCT scores of elementary school children had a significant relationship with adult creative achievement.

Longitudinal studies on the developmental trend of creativity

Researchers such as Torrance, in the field of creativity, have also tried to formulate a developmental trend of creativity as those who have done in delineating the developmental trend in intelligence and morality. Is the developmental trend of creativity a gradual but steady rise in creativity until a peak is reached? Has the developmental curve one peak or multiple peaks over time? Can a lump observed in the empirical studies be attributed to the need of school children to conform to the expectations in the school settings, or should it be attributed to other alternative interpretations? Can creative development be divided categorically into different stages, such as the stages in cognitive development (sensorimotor, preoperation, concrete operation, and formal operation) and those in socio-moral development (anomy or nonregulation, heteronomy, and autonomy)? These questions can be addressed by means of longitudinal studies. A longitudinal study was conducted by Claxton and colleagues in 2005 to explore the developmental trends in creativity longitudinally from the fourth grade through ninth grade. From 184 fourth grade predominantly middle class White students from rural schools, only 25 students (8 boys, 17 girls) completed all assessment tasks at three data collection points in the fourth, sixth, and ninth grades. Two instruments were used: (a) the Test of Divergent Thinking, comprising 12 unfinished pictures to be completed within a specific time frame and designed to measure fluency, flexibility, originality, elaboration, and title factors; (b) the Test of Divergent Feeling designed to measure dimensions of motivation and personality characteristics in creativity including curiosity, complexity, imagination, and risk taking factors. The results showed that significant increases in mean total scores were found from the sixth to ninth grades on both the Test of Divergent Feeling and the Test of Divergent Thinking, while no significant change in mean total scores was found between the fourth and the sixth grades on either.

Linear Structural Relations (LISREL) or Structural Equation Modeling (SEM) Analysis

This kind of research can be cross-sectional or longitudinal. In a regression equation, it is assumed that the independent variables must be mutually independent. If the independent variables are correlated, then the problem of multicollinearity emerges, by which the effect of a weaker variable would be partialled-out by another stronger variable. SEM analysis can improve this weakness, though not completely because it is possible that a correlation between two latent variables may exist. In an SEM analysis, a common factor among the correlated independent variables is extracted and labeled as an independent latent variable (ξ) or exogenous variable. The latent variable is a construct or a concept, it is not observable, but can be represented by observed variables. If there are correlated dependent variables, a common factor can also be extracted and labeled as a dependent latent variable (η) or endogenous variable. The gamma (γ) coefficient is similar to a regression coefficient, and depicts the effect of the independent latent variable on the dependent latent variable. In a structural equation model it is possible that more than two independent latent variables and more than two dependent latent variables are analyzed.

ζ is the error term of the structural equation model, and equals to $1 - R^2$, representing the variance of the dependent latent variable(s) that cannot be explained by the independent latent variable(s). Figure 2 is an SEM analysis with artificially generated data for the purpose of demonstration. Suppose that we want to understand the contribution of intelligence and creativity to the innovative performance of faculty members at technological universities. Under the agreement and cooperation of the conference organizer and sponsor agent, 300 participants in an academic conference on technological innovation are drawn as samples. They are faculty members of private or public technological universities. The participants are asked to take four tests (two IQ tests and two creativity tests) during their free time at a 3-day conference and paid \$50 each for taking the tests. They were also asked to send their list of publications including patents and scientific papers in self-addressed stamped envelopes to the researcher and are assured of confidentiality. Those who do not return the information within 2 weeks are contacted by telephone and asked to mail the publication lists. It is further assumed that there are 200 valid samples. The result of a LISREL analysis is displayed in Figure 2. All the estimated parameters in the path diagram are statistically significant. The artificially generated data in the path diagram can be explained as follows:

1. the symbol in a square means an observed variable and that in an ellipse means a latent variable;
2. the direction of an arrow means the direction of influence;
3. innovative performance (η) was significantly influenced by creative ability (ξ_1) as well as general ability (ξ_2) and the former ($\gamma_1=0.82$) had greater effect than the later ($\gamma_2=0.66$);
4. if a correlation matrix is used as input data, then the ϕ coefficient means the correlation between two independent latent variables, the coefficient is 0.54;
5. technological creativity (X_1) can better represent the creative ability of the faculty members at technological universities than general creativity (X_2), the lambda coefficients are 0.93 and 0.84, respectively;
6. the scores of a quantitative aptitude test, the Arithmetic reasoning test (X_3) can better represent the general ability of the teaching staff of technological universities than that of a verbal aptitude test, the General Classification Test (X_4), the lambda coefficients are 0.82 and 0.72, respectively;
7. the yearly mean number of awarded patents (Y_1) can better represent innovative performance than that of number of published scientific papers (Y_2), the lambda coefficients are 0.83 and 0.71, respectively;

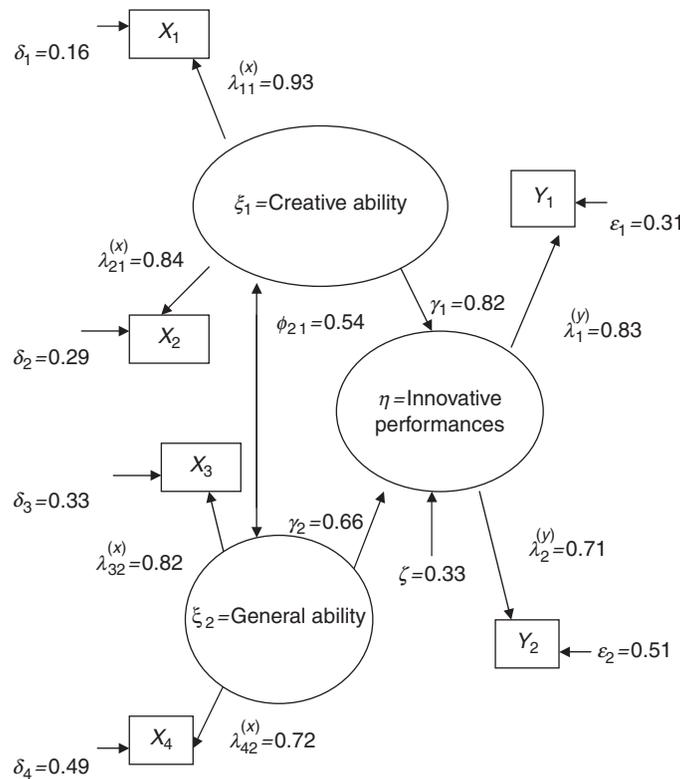

Figure 2 A structural equation model with artificially generated data, where X_1 = Technological Creativity Test (Treasure Hunt on a Deserted Island); X_2 = General Creativity Test (Figural Torrance Tests of Creative Thinking); X_3 = Arithmetic Reasoning Test (involving mathematical reasoning and problem solving); X_4 = General Classification Test (verbal test involving word comprehension and verbal reasoning); Y_1 = Yearly mean number of patents (total number of patents within the past 5 years \div 5); Y_2 = Yearly mean number of scientific papers published in peer-reviewed academic journals (total number of scientific papers within the past 5 years \div 5); η = dependent latent variable; ξ_1 and ξ_2 are the first and second independent latent variable; γ_1 and γ_2 are the first and second structural coefficient; ϕ_{21} = correlation between two independent latent variables; ζ = error term in the structural equation; δ_1 to δ_4 are the measurement errors in the observed independent variables (X_1 to X_4) respectively, and ϵ_1 and ϵ_2 are the measurement errors in the observed dependent variables (Y_1 and Y_2) respectively.

8. the error term (ζ) of the total model is 0.33, depicting that the independent latent variables can explain 67% of the variance of the dependent latent variable, that is, $R^2 = 1 - 0.33 = 0.67$; and
9. δ_1 to δ_4 are the error terms of the observed independent variables (X_1 to X_4) respectively, and ε_1 and ε_2 are the error terms of the observed dependent variables (Y_1 and Y_2) respectively, they are measurement errors, and the smaller the coefficient the better.

In 2006 Livne and Milgram used SEM analysis to investigate the construct validity of domain-specific abilities in mathematics. The sampling process in Livne and Milgram's research was a nationally stratified method. Altogether, a sample of 1090 tenth- and eleventh-grade students (565 males and 525 females) representing a wide range of intellectual abilities, was drawn from 22 public schools in urban and rural areas. Livne and Milgram used scores on the cognitive ability test, which assesses verbal, numerical, and nonverbal/figural abilities, and Raven's Advanced Progressive Matrices (APM), which uses abstract figures to measure reasoning, as the observed variables for the independent latent variable 'intelligence.' The observed variables used to represent the independent latent variable 'creativity' were scores on the Verbal Creativity Test, in which the students must generate different reasonable and innovative sentences out of four given letters, and that of the Application Test, in which students must produce different reasonable and innovative applications of given objects. The observed variables for the dependent latent variable 'school performance' were the grades or marks of Languages, Math-Physics, Science, and Humanities. Their structural equation model demonstrated that general ability, which was represented by IQ scores, could predict academic ability in mathematics (represented by the final grade in mathematics and an open-ended academic mathematical problems test), but not creative ability in mathematics (represented by creative out-of-school activities in mathematics and open-ended creative mathematical problems test), and vice versa, that creative thinking, which was represented by ideational fluency, could predict creative ability in mathematics, but not academic ability in mathematics.

The fit indexes most generally used to check whether a structural equation model is a statistically good-fit are that: (a) the χ^2 is not significant; (b) the Goodness-of-Fit Index (GFI) or the Adjusted Goodness-of-Fit Index (AGFI) is greater than 0.90; and (c) the Root Mean Square Residual (RMSR) is less than 0.05 or the Root Mean Square Error Approximation (RMSEA) is less than 0.08. If a model does not meet the criteria of the good-fit indexes, the modification index may be used to evaluate and modify the model.

Meta-Analysis

Meta-Analysis for Research Using Single-Case Experimental Designs

It is difficult to compare the effectiveness of more than two different interventions with a single single-case experimental design. A meta-analysis of research using single-case experimental designs can be used to overcome the difficulty. In the area of creativity, meta-analysis not only can be used to compare

the mean effect sizes of the different independent variables, the mean effect sizes of the different dependent variables (i.e., which components of creativity are more difficult to be fostered), but also the mean effect sizes of the different moderators (i.e., whether study characteristics, such as intelligence, gender, and age of participants; setting of treatment, and type of experimental design influence the effectiveness of independent variable). Whereas, the body of empirical studies using single-case experimental designs to investigate creative behaviors is growing, the number at present is too few to be used for a meta-analysis in creativity.

Meta-Analysis for Research Using Between Groups Experimental Designs

The function of meta-analysis is to use the standard deviation as the measurement unit to convert the results of research into effect sizes for the purpose of comparison. It can also aid in solving controversies of different findings on a certain topic (i.e., where some researchers found that Variable A had significant correlation with Variable B or Variable A had significant effect on Variable B, but the findings of other researchers could not be used to confirm that result or showed statistical significance in the opposite direction) by means of averaging the effect sizes of a variable investigated by different researchers. The general procedure of meta-analysis is as follows:

1. Locating the relevant studies. Using key words as search terms to conduct a computer search of the relevant studies from different data bases such as ProQuest, PsycINFO, and EBSCOhost. The creativity related journals such as *The Creativity Research Journal* and *Journal of Creative Behavior* must be searched manually. Some articles can also be traced from the references of selected studies. The required studies must contain at least correlation coefficients or means and standard deviations to be converted into effect sizes.
2. Categorizing the variables to be investigated, such as independent variables and dependent variables. In order to examine whether the effect of the independent variable on the dependent variable can be generalized to different settings, experimental designs, age and sex of participants, and moderators must also be coded.
3. Calculation of effect size. For the formulas of conversion were proposed by Cooper and Hedges in 1994. The most frequently used conversion formulas are:

$$\Delta = \frac{M_e - M_c}{SD_c} \quad (1)$$

$$g = \frac{M_e - M_c}{\sqrt{\frac{(n_e - 1)SD_e^2 + (n_c - 1)SD_c^2}{n_e + n_c - 2}}} \quad (2)$$

$$g = \sqrt{\frac{4(N - 1)}{N} * \frac{r}{\sqrt{1 - r^2}}} \quad (3)$$

where Δ is the effect size proposed in 1976 by Glass, while g is that proposed by Hedges. Glass' Δ has a pure denominator because it is free from contamination by the treatment. However, the bias and variance of g are both smaller than that of the corresponding Δ . M_e , SD_e , and N_e are the mean (M), standard deviation (SD), and the number of

Table 1 Strengths and weaknesses of each method as well as the difficulties or limitations in application

<i>Research method</i>	<i>Strength</i>	<i>Weakness</i>	<i>Difficulty or limitation in application</i>
Experimental studies			
Between-group experimental designs			
Real experimental designs	Internal validity is not threatened	Can only used in controlled settings	Researchers are often not able to carry out randomization of grouping in natural settings
Quasi-experimental designs	Can be applied in natural settings	Internal validity may be threatened	Dependent and background variables of the experimental and control group may be not equal before treatment is introduced
Observational method	A hypothesis can be formulated awaiting a test in a real experimental study	Weak for the study of causal effect	Two observers must be trained to reach high reliability in their observations
Single-case experimental designs	Effect of a strategy of fostering creativity for a single participant can be tested	Weak for the purpose of building a theory	Generalization of results to other persons is limited
Correlation methods	Large quantity of variables can be investigated in a survey study	Weak for the study of causal effect	Measurement error may be large if the data are collected through self-report
Cross-sectional studies on developmental trends of creativity	Data can be collected at a single time point	Representative participants must be recruited on a large scale	Difficulty in carrying out representative sampling of participants in each age or grade
Predictive validity studies	Causal effect can be investigated	Effects of unknown variables occurring between waves of data-collection and causing disturbance can not be precluded	Not easy to operationally define a creative performance as a criterion variable
Longitudinal studies on developmental trends of creativity	Data of the same group of participants are comparable throughout all stages of development	Long-term tracking needed	High attrition rate of the number of participants during tracking
Structural equation modeling	Used to investigate the causal effect of independent latent variables on dependent latent variables	Multi-collinearity between independent latent variables may not be totally precluded	Usually necessary to use a modification index to modify the model so that the criteria of goodness-of-fit are met. Additionally the optimal sample size is 200, small sample size is not suitable for analysis
Meta-analysis			
Meta-analysis for research using single-case experimental designs	When using the PEM score as the unit of measurement, the relative effectiveness of different independent, dependent variables, and moderators can be analyzed	Number of studies using single-case experimental designs to investigate creativity is too few to be used for a meta-analysis	Not easy to classify the variables into categories
Meta-analysis for researches using between-group experimental designs	Effect size can be used as the unit of measurement to show the relative effectiveness of different independent and dependent variables, and moderators can also be analyzed	Studies investigating more than two independent variables are not suitable to be included in meta-analysis because of the confounding of effects	Not easy to classify the variables into categories

participants (N) of the experimental group, respectively; M_e , SD_e , and N_e are the M , SD , and N of the control group, respectively; N is the total sample size, r is the correlation coefficient.

- Analyzing the data. In the case that one article has several effect sizes, these effect sizes are frequently correlated with each other. Therefore, when applying the statistical tools to analyze the data in a meta-analysis it must be kept in mind that the assumptions of parametric statistics should not be

violated, and one should test whether: (a) the residuals are independently distributed, that is, the data should not have significant autocorrelation, which is the correlation between i th and $i+1$ of the whole set of effect sizes; and that (b) the variance of the residuals is homogeneous. If these two important assumptions are violated, then non-parametric statistics should be used instead of parametric statistics. For example, Kruskal–Wallis one-way analysis of variance by ranks (K-W ANOVA) can be used to analyze the

difference between the mean ranks of more than two sub-categories of a variable and the Mann-Whitney U test can be used to make *post hoc* comparisons.

Conclusion

Experimental studies and correlation methods have been commonly used while the use of single-case experimental designs and meta-analysis in the creativity research are still new. Single-case experimental designs and real experimental designs are designs with internal validity. Meta-analyses using effect size as the unit of measurement not only can be used to compare the relative effectiveness of different independent variables, the dependent variables, and moderators but also to solve controversies in certain areas of research in creativity. **Table 1** summarizes the strengths, weaknesses, as well as the difficulties or limitations in applications of each method.

Rewards and Creativity

The Reward – Creativity Controversy

Dozens of studies have examined rewards' effect on creativity. Despite a sizable literature, the question of whether rewards enhance or hinder creativity remains controversial. Many creativity scholars and laypersons believe that rewards are an effective motivator for various kinds of performance including creativity. Among other reasons, people who are offered a reward may be more creative because the reward is desirable or because it symbolizes the person's status as a creative person. In contrast, others believe that performance on creative tasks suffers when rewards are offered. Perhaps reward distracts attention from and decreases interest in creative tasks, and lessens perceived control over one's choices.

Ample evidence has been cited to support both positions, as the results of studies examining the relationship between rewards and creativity have been inconsistent. Many studies have found that rewards increase creativity. For example, Robert Eisenberger and Michael Selbst found that children who were rewarded with pennies for creative responses on an initial word construction task subsequently produced more creative responses on a subsequent different picture writing task. In contrast, children who were rewarded for noncreative responses on the word construction task produced less creative drawings on the picture writing task. In contrast, other studies have found that rewards decrease creativity. For example, Arie Kruglanski, Irith Friedman, and Gabriella Zeevi found that high school students promised a reward for their participation were less creative on verbal tasks than were those not promised a reward.

As we shall show, the methodologies used by the researchers asserting positive effects of reward on creativity and those used by researchers asserting negative effects are quite distinct. Lacking an appreciation of these procedural differences, the two sides seem only to grow more vociferous in the advocacy of their original positions, consistent with their disparate ways of viewing human psychology.

We first turn to a discussion of the differing theoretical positions, including their historical background, followed by a description of their associated methodological differences that may be responsible for the difference in the findings. We then present the results of a meta-analytic review of the literature, informed by these procedural differences, that brings order and regularity to the findings, and conclude with practical implications.

Behaviorist Approaches

Rewards are consequences that strengthen the performance on which they are contingent. Evolution provided people with a strong motivation to pursue stimuli that enhance chances of survival. Humans, with their strong intellectual and socializing

capacities, are attracted to many acquired rewards in addition to biologically advantageous satisfiers. These include money and symbolic rewards such as prizes. Rewards also include information that is interesting in its own right, such as news about sports or politics, or information that serves as a means to an end. Some rewards also meet socio-emotional needs as in expressions of approval, esteem, or caring.

A long held view of motivation, embodied in Jeremy Bentham's psychological hedonism, emphasizes the importance of reward as a basis for human action. Bentham stated that "Nature has placed mankind under the governance of two sovereign masters, *pain* and *pleasure*." The behaviorists showed the power of reward to influence many aspects of human performance. So it seems natural to suppose that creativity, as with other human activities, can be enhanced by reward. Yet, creativity is different from behaviors or activities that are readily identifiable and occur frequently and therefore can be easily rewarded. By its nature, creativity involves the unusual. Sometimes a creative problem or goal has multiple useful solutions, as in generating advertising slogans for an airline. Sometimes only a single solution is correct as in the historic discovery of the structure of humans' DNA. But in either case, because the creative response is not in the individual's prediscovery repertoire, behaviorist approaches offer limited information concerning the processes used to generate such behavior.

In the past, behaviorists have tried to deal with this issue by stressing the importance of trial and error in creative performance. In this view, Kohler's apes' insights into using sticks or stacking boxes to retrieve bananas 'at first sight' were actually the result of previous kinds of unnoticed experience. Similarly, humans generally do not come to creative insights out of the blue, as has often been claimed by famous individuals to demonstrate their own brilliance, but as part of a considerable number of reconsiderations of facts and information obtained from false leads and premature solutions. The small gains in understanding acquired along the way to creative solutions and the social approval for perseverance at creative attempts may encourage the individual toward a greater contribution. For example, James D. Watson and Francis Crick, the discoverers of the double helix molecular structure of human DNA, were encouraged by many small successes along the way to their discovery. Those who study the *repeated* reward to enhance creative responses (e.g., novel uses for common objects), rather than a *promised reward* for a single final highly creative product, do so because they are interested in the cumulative motivational effects of reward.

But Watson and Crick did not simply undergo trial and error, although this was part of it. They engaged in complex directed cognitive processing. What role did reward play? We think Watson may have had a keen insight here. He stated that the anticipation of the Nobel Prize kept him highly focused on the task at hand and motivated to do the hard work despite

his strong inclination to putting all aside for a good time. And, we suggest, the information associated with solving parts of the puzzle along the way served as a secondary reward.

Watson liked science for its own sake but wanted to be a famous scientist more than a practicing scientist, and he stopped actively carrying out research soon after receiving the prize in order to direct the science of others as an administrator for the rest of his career. As in this example, reward can have a powerful effect on creativity. Admittedly, these examples tell us primarily about how rewards can intensify and direct individuals' efforts and tell us relatively little about the complex cognitive processes that underlie creativity. Still, we will see a very effective formula for enhancing creativity: provide what the individual wants, contingent on creativity, and make this creativity contingency clear.

Behaviorist approaches maintain that reward will increase creativity so long as the reward is valued by the recipient and the nature of the contingency can be readily discriminated. Thus, in most studies of creativity the reward is based on repeated creative performance, and this contingency is communicated to participants by verbal instructions. This is deemed necessary because participants who are simply told they will receive a reward may not receive enough experience with the reward contingency to understand the reward depends on creativity and thus would fail to display novel performance. For example, if a child is asked to state uses for common objects and is rewarded for every uncommon use, the child has a low base level of providing uncommon uses and may be very slow to discriminate the dependence of reward on creativity. Thus, the typical behaviorist situation involves an experimental condition in which the nature of the creative performance is defined by instructions and the individual is repeatedly rewarded for a creative response. A control group is included with no reward and no mention of creativity.

The results of these studies have been impressive. Decades ago, a review of 20 such studies by Andrew Winston and Joanne Baker concluded that reward can be used to increase divergent thinking. Unfortunately, the findings reviewed by Winston and Baker confounded the instructions to be creative with the reward for being creative. Perhaps the simple instruction to be creative was responsible for the findings.

Romanticist Approaches

Another philosophical tradition, romanticism, equates creativity with freedom, and views reward as a kind of constraint on freedom that discourages creativity. This view can be traced to the early renaissance in the Italian city states and was associated with such subsequent popularizers as Jean Jacques Rousseau in France, and the American transcendentalists Emerson and Thoreau. The romanticists saw the excesses of early industrialization as producing emptiness in the lives of working people. The romanticists embraced sensuality and nature, and rejected the enlightenment's dependence on reason in place of intuition and feeling. In modern guise, romanticism rejects constraints on freedom as antithetical to creativity. We hasten to add that we are using the term *romanticism* in the historical and philosophical sense and not with the alternative meaning associated with a lack of clear and rational thought. Specifically, some researchers

have viewed reward as representative of control, emblematic of the kind of control represented in the excesses of the factory system, against which the romanticists rebelled.

Those contemporary approaches hewing to this approach, such as Teresa Amabile's early views of creativity and Edward Deci and Richard Ryan's analyses of intrinsic interest, place reward in the same category as constraints on performance such as time restrictions and limitations on how one is allowed to carry out an assigned task. Reward is assumed to be experienced as a loss of self-determination, with a lessened interest in the task for its own sake (intrinsic interest), a greater focus on the narrow requirements necessary to obtain the reward, and a necessary decrease in creativity. This view is understandable. Many people are forced to take jobs they abhor because they have low skills and must do so because of the pay. Others may possess considerable skills and talents and put them to use in jobs they dislike because the jobs require little effort or because the pay is high. In these situations pay seems constraining. Moreover, as Amabile suggests, a focus on rewards may limit attention toward what it takes to obtain the reward to the detriment of attention to novel information that is useful for creativity. Indeed, James Watson, in his search for the DNA molecular composition declined to attend lectures that were not directly related to his quest, and this narrowness might have slowed him down had he chosen to pursue additional research problems.

Common Ground

As we have seen, the behaviorist approach was flawed methodologically by the confound between the use of reward and instructions that told recipients that creativity was expected of them. Thus, most of the evidence seems to favor the romanticist view holding that reward decreases creativity. And yet the argument against rewards as a source of creativity seems too sweeping. Is it actually common for individuals to feel constrained by rewards, reducing their feelings of freedom and self-determination and narrowing their attention span? Further, can such a powerful motivator as reward be ineffective for this one category of human behavior? Three decades ago the first author began his research on creativity after being approached by a student, Michael Selbst, who had heard about the decremental effects of reward on creativity and wanted to do research with me on the topic. As a newcomer to the field who had no commitment to either camp in the controversy over whether reward decreases or increases creativity, I was startled by two seeming discontinuities in the empirical literature.

First, most of the studies reporting that reward increased creativity were carried out by behaviorists who made reward contingent on repeated creative performance. In contrast, most of the studies reporting that reward reduced creativity involved giving a promise of reward for unspecified performance. Was it possible that whether reward increases or decreases creativity depends on whether recipients understand that the reward depends on creative performance rather than on conventional performance? Second, there were very few studies that reported whether reward reduced perceived self-determination, a key mechanism that Deci and Ryan suggested was responsible for lessening the effects of reward on intrinsic interest. Is it really the case that reward reduces perceived self-determination?

In a series of studies, my colleagues and I found that when the relationship between reward and creativity was made clear to participants, creativity increased. This clarity could be achieved either by instructions or by a preliminary task in which instructions for creativity were used. For example, Eisenberger and Linda Rhoades asked college students to generate creative story titles, with or without the promise of reward. Students promised reward for creativity produced story titles that were rated as more creative by judges than did students given the same instructions without the promise of reward.

Because people are rewarded more often in everyday life for conventional rather than creative performance, individuals offered a reward for nonspecific performance, as in the typical romanticist study, may believe that conventional performance is the most effective way to obtain the reward and respond accordingly. A study by Amabile is telling. She found that offering children a reward for constructing a collage, without an indication that creativity was expected, produced less creativity than the same instructions without the offer of reward. Yet, the children offered the reward constructed collages that were better planned and organized and more representational than those of children in the control group. Lacking guidance concerning the type of performance that was desirable, the children may have attempted to obtain the reward by the conventional performance that had been rewarded in the past.

The behaviorists appear to produce creativity by making reward contingent on creative performance. The romanticists appear to reduce creativity by being vague about the nature of desirable performance. However, it is also the case that individuals generalize their experience from similar situations so that, as the first author has found in many studies, reward for creativity in one task with clear directions increases creativity in subsequent tasks with vague directions.

In a study and subsequent meta-analytic review of the literature, the first author and his colleagues also found that, rather than reducing perceived freedom and self-determination, reward increased perceived self-determination. Compared to a control group simply given task instructions, a rewarded group experienced increased self-determination. Eisenberger and Linda Shanock explained these findings as follows.

The use of reward in everyday life conveys not social control but increased self-determination. People understand that reward's use in everyday life is utilitarian, involving the reward giver's lack of control over the potential reward recipient; those offering the reward believe that favorable consequences are needed to obtain the cooperation of the person being asked to carry out the task. Specifically, the promise or repeated use of reward communicates that (a) the individual or group giving the reward lacks control over the performance of the potential reward recipient, and (b) the recipient can, if desired, decline the reward and not act as directed.

We now summarize the conclusions of a quantitative review, combining the findings of similar studies so that an overall effect size can be determined for each type of reward procedure.

Meta-Analytic Review of the Literature

Although a diversity of study designs has the potential of furthering knowledge about rewards and creativity, it also

makes it difficult to make sense of the findings. The literature on rewards and creativity is highly diverse in terms of where and how rewards and creativity have been studied and who and what has been studied. Researchers have examined the effects of rewards on the creative performance of people of various ages (children, college students, adults). Additionally, research has been conducted with different types of rewards (praise, activities, money, prizes), with different types of creative tasks (creative writing, collage-making, divergent thinking tasks, in-basket tasks), in different settings (laboratories, schools, workplaces), with a variety of research designs (experimental and non-experimental, within- and between-subject), and with different reward schemes (before, during, and after performing a task).

Kristin Byron and Shalini Khazanchi's recent meta-analysis of more than 60 studies examining rewards' effects on creativity in humans serves to enlighten this debate by using this powerful statistical technique to average the findings separately by category. Although there is no simple answer to the question "Do rewards help or hinder creativity?," there are some generalizations – and some finer points – that can be derived from this meta-analysis regarding rewards' effect on creativity. In fact, these results generalize across different types of creative tasks (e.g., divergent thinking tests and the creation of creative products such as collages) and different types of studies (e.g., experimental studies in laboratory and other settings and nonexperimental field studies conducted in work organizations). **Table 1** summarizes the results of the meta-analysis that are reviewed below.

In general, the results of the meta-analysis found that rewards increase creative performance when people expect that the rewards are contingent on *creative* rather than routine performance. Clarifying a contingency on creative performance can be accomplished through a variety of means. The two most straightforward and direct ways are to simply specify that rewards are only for creative responses or to reward creative

Table 1 Summary of meta-analytic results examining the rewards-creativity relationship

<i>Factors that Increase, Decrease or Have No Effect on creative performance</i>	
Increase	<ul style="list-style-type: none"> ● Creativity-contingent rewards produce greater creativity than performance-contingent rewards which, in turn, produce greater creativity than participation-contingent rewards. ● Creativity is increased by the value, number, proximity or choice of rewards. ● Adults are more responsive to rewards than are children. ● Rewards influence the number of creative ideas more than the originality of creative ideas. ● Rewards generate greater creativity on complex tasks with diminishing returns as the task becomes highly complex.
Decrease	<ul style="list-style-type: none"> ● Participation and completion-contingent rewards decrease creativity.
Have No Effect	<ul style="list-style-type: none"> ● Simple competition fails to increase creativity. ● No one reward type (e.g., praise, money, desirable activities) has been found to be generally more effective than another at generating creativity.

responses thereby creating an expectation that future rewards are also contingent on creativity. Results of many studies suggest that people are more creative when they are told that they have to be creative to receive a reward or when they have received rewards in the past for creative (rather than noncreative) responses. Other methods are also effective at conveying to people that creativity is expected, desirable, and will be rewarded. For example, many of the studies that successfully motivated creativity did so by providing instruction on how to be creative or providing a model of creative work – both of which probably convey to those who are offered rewards that creative performance is likely to be rewarded.

Several other factors seem to improve the likelihood that rewards can help people to be more creative. First, more rewards are better than fewer rewards. People who were both praised and offered other types of rewards for being creative were more creative than people only given praise or only offered other types of rewards. Second, when monetary rewards are contingent on creativity, the size of the reward also appears to matter. In the studies meta-analyzed, people offered more money for being creative were more creative than were those offered smaller monetary rewards. Third, creativity-contingent rewards are more effective at motivating creativity from adults than from children. Lastly, when rewards are contingent on creativity, having the reward in sight appears to be better at motivating creativity than does having the reward out of sight. However, this finding may be truer for adults than for children – who may be more easily distracted by having rewards in sight.

The existing evidence suggests that creativity-contingent rewards motivate people to be more creative. However, the results of the meta-analysis add a few caveats to that statement. First, creativity-contingent rewards are effective at motivating both different and highly original responses, although they are more effective at motivating people to generate more responses (e.g., ideas, artistic forms) than they are at motivating people to produce highly original responses. Second, the results suggest that rewards are less effective at producing creative responses on highly complex creative tasks. Rewards are increasingly effective at motivating creative performance on tasks of greater complexity but only to a point. On highly complex tasks, rewards are still effective – though less so – at motivating creativity, perhaps because prior skill level or aptitude constrains any motivating effect of reward.

In addition to pointing out factors that may increase creativity, the results of the meta-analysis also point out factors that *decrease* the likelihood that rewards will help people to be more creative. Namely, rewards are less effective at motivating creativity when people do not expect or are unlikely to expect that the rewards are contingent on creative performance. When rewards are offered for completing a task or participating in a task, rewards seem to have no effect on creativity. For example, Teresa Amabile, Beth Hennessey, and Barbara Grossman found that children who received a reward (being able to play with a Polaroid camera) in exchange for later participating in a story-telling task subsequently told less creative stories. In contrast, those who did not receive a reward (playing with the camera was not linked to their participation in the story-telling task) told more creative stories.

Many studies that have sought to examine the effects of rewards on creativity have used these types of rewards – to an

unsurprising effect. When people are told that rewards are for merely completing or participating in a task or when people receive prior rewards for output irrespective of its creativity, creativity tends to decrease or, at the least, not increase. With this type of reward, referred to as completion-contingent rewards, rewards appear unable to motivate people to be more creative. Alternately, when rewards are offered for performance but not explicitly *creative* performance, they are less effective at motivating creativity. With this type of reward, referred to as performance-contingent rewards, rewards motivate people to be more creative but less so than for creativity-contingent rewards.

As discussed above, creativity-contingent rewards increase creativity – and, while some factors serve to enhance or mitigate this effect, other factors seem to have no effect at all. Namely, what type of reward is offered and whether the reward is offered competitively or noncompetitively do not seem to significantly affect the relationship between rewards and creativity. According to the results of the meta-analysis, whether people are offered praise, money, desirable activities, or prizes to be creative does not alter rewards' effect on creativity.

Clearly, much research has sought to illuminate the relationship between rewards and creativity. Despite this sizable literature, there are some questions that remain unexplored. First, many scholars have suggested that there may be important individual differences that may account for the mixed results found in the literature. Individual differences that have been put forth as potentially important include intelligence, thinking style, creative aptitude, sex, and others. For example, Linda O'Hara and Robert Sternberg found that, when they were not given any special instructions about how to complete a potentially creative task, people who tend to play with their own ideas were more creative than were people who tend to analyze and evaluate ideas. It may be that rewards similarly interact with thinking style to determine creative performance. Rewards may increase creative performance of those who tend to analyze and evaluate ideas because they are less inclined to think creatively in the absence of a specific motivator. Conversely, those who tend to play with their own ideas may be less affected by rewards because they are already inclined to think creatively.

Second, many studies outside the creativity literature have examined the relative effects of different reinforcement schedules on individuals' motivation and subsequent performance. Although there are few studies in the creativity literature that have examined reinforcement schedules, it seems likely that the findings regarding motivation and performance on noncreative tasks transfer to creative ones. Specifically, rewards that are administered on a variable reinforcement schedule, such that individuals are rewarded intermittently for creative performance, are likely to be more motivating than are rewards that are administered on a continuous reinforcement schedule, such that individuals are rewarded every time or at regular intervals for creative performance. Reinforcement schedules may also help determine how long-lasting the effect of rewards is. Unfortunately, existing research does not allow for firm conclusions about the extent to which rewards administered under different reinforcement schedules may affect performance and persistence on creative tasks.

Additionally, how rewards are administered and distributed for creative output probably determines persistence. Being

creative often results in false starts or ideas or products in need of further refinement. Smaller rewards administered during the creative process may help to increase persistence toward more novel and appropriate products or ideas. Further research may examine how rewards can be used to increase experimentation and risk-taking – both of which are essential to the creative process.

In summary, the bulk of the evidence suggests that rewards can increase creativity. To do so, the rewards must be clearly contingent on creative – rather than routine – performance. When people are not clear that they should be original and innovative, rewards are less effective at increasing creativity. Much insight can be derived from existing studies on rewards and creativity, although more work needs to be done to further what is known about how and when rewards affect creativity.

Promoting Creativity at Work and School

Many educators wish to increase their students' creativity, many managers wish to increase their employees' creativity, and, as a society, we often wish to increase the creativity of the artists, musicians, and writers whose work we enjoy. Fortunately, research on rewards and creativity offers insights about how to achieve these goals. Below, some of the primary lessons gleaned from research on rewards and creativity are presented.

First, be explicit about expectations. For people to be creative, they must know that creative work is expected. Without a clearly stated expectancy regarding creativity, people are likely to assume that other aspects of performance such as technical goodness or speed are more valued. Therefore, to promote creativity at work and school, educators and managers should explicitly state that creative work is desired and valued. The key issue to improving the effectiveness of rewards is to make it clear that receiving the reward is contingent on creative performance.

Second, offer training and modeling to increase creative skills. When people receive training or modeling of creative behavior, they learn how to be more creative. In addition to learning new skills, training and modeling also help to clarify expectations about what is valued. As stated above, people are more likely to be creative when they understand that creativity is expected and considered desirable. When people are trained to be more creative or are provided with a role model who exhibits creative behavior, then they come to understand that they should also seek to be creative.

Third, different types of rewards may help to increase creativity. Praise, privileges, money, and prizes have all been found to successfully motivate creativity. It is, however, always wise to offer people rewards that they personally value, as rewards that are considered unattractive are unlikely to be motivating. Further, although the type of reward does not seem to matter in general, educators and managers may consider offering multiple rewards. It may be that offering more rewards increases perceived choice and improves the likelihood that those being offered the reward will find at least one of the rewards offered attractive.

Fourth, make sure rewards are distributed equitably. What is equitable? People probably make two primary considerations when determining the fairness of a reward in response to their creative output. First, they probably consider the extent

to which their rewards are fair in comparison to those rewards received by others. For this reason, people who are more creative should receive greater rewards. Second, individuals probably consider the extent to which their rewards are fair in comparison to the value of their creative work. For this reason, people who produce more valuable creative responses should receive greater reward. For example, if an employee finds a creative solution that saves his or her employer millions of dollars, then the employee probably expects a greater reward than if the employee had developed a creative solution that did not prove as valuable. This positive reinforcement compensates employees, communicates gratitude to employees for their efforts, and sends a message regarding expectations to other employees. It seems likely that employees who are *not* rewarded for being creative are likely to feel that they are not being treated fairly and may subsequently withdraw from being creative at work.

Lastly, as mentioned above, rewards should also be offered for experimentation and risk-taking – even when individuals' attempts result in failure. Managers and educators should realize that much of being creative results in false starts. It is by taking risks, experimenting with new ideas of uncertain value, and forging into uncharted territory that people may eventually produce the most creative ideas, products and processes. For this reason, rewarding only creative ends – and failing to reward creative effort – is unlikely to sustain creative behavior. Managers and educators should thus tolerate mistakes and view them as a necessary part of the creative process.

Conclusion

The issue of whether reward increases or decreases creativity has been marked by considerable controversy, with substantial data marshaled for both views. In the present review we have considered how the behaviorist view of human nature has led to a predisposition to view reward as increasing creativity while the romanticist view has promoted the view that reward decreases creativity. Our analysis of the methodological differences in studies reporting these two kinds of outcomes and the results of a meta-analytic review begin to bring clarity and order to the research literature on rewards and creativity.

Our major conclusions are that reward for creativity increases creativity when recipients clearly discriminate the necessary contingency. Rewards for high performance, not specifically creative performance, increases creativity to a lesser extent. In contrast, noncontingent reward generally reduces creativity. We need more and better theory concerning why and how these effects take place rather than a continuation of the ongoing disagreement concerning whether reward generally increase or decreases creativity.

Risk-Taking

V P Prabhu, California State University, Los Angeles, CA, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Problem framing Refers to whether a situation is presented to an individual in a positive or negative light.

Risk perception An individual's estimation of the risk inherent in a situation.

Risk preferences An individual characteristic that influences individual actions. Those who take pleasure in facing challenges are more likely to take risky actions and vice versa.

Risk propensity An individual's risk taking tendencies.

Risk taking Actions taken when the consequences or probability of the outcomes are unknown or partially known.

Risky shift On average, individuals will privately recommend a greater degree of risk taking after group discussion than these same individuals had privately recommended before.

Introduction

Twenty years from now you will be more disappointed by the things that you didn't do than by the ones you did. So throw off the bowlines. Sail away from the safe harbor. Catch the trade winds in your sails. Explore. Dream. Discover.

Mark Twain

Risk taking in its simplest form may be defined as involving actions taken when the consequences or probabilities of outcomes are unknown or only partially known. Risk taking interacts with creativity. Creativity involves generation of novel, original, and unique ideas for procedures and processes that are appropriate and significant to the problem or opportunity presented. Thus, both creativity and risk taking greatly influence building a climate of idea generation. Creativity involves taking chances and risks. Although risk taking may or may not be creative, both share a common domain of factors that affect them (see [Figure 1](#)). Although creative people are risk takers, not all risk takers are creative.

A review of the extensive literature reveals numerous references to the risk-taking nature of creative persons. There are now several validated scales which measure risk taking and various forms of the construct such as global risk taking, risk orientation at work, risk attitude, and domain specific risk taking. Studies have provided empirical evidence that risk taking is an important predictor of creativity in different domains including entrepreneurship and difficult sports such as rock climbing. What follows is a brief description of the role played by risk taking in entrepreneurship which is closely associated with creativity and decision making.

Risk Taking and Entrepreneurship

The importance of creativity in the corporate world can hardly be overemphasized. The words of Joseph Anderson seem quite appropriate:

Creativity is the gift and discipline that provides the competitive edge – in marketing, production, finance, and all of the other aspects in an organization. Firms and managers crave it. Awards are given

for it. Incentives encourage and cajole it. But it's still the most elusive weapon in an executive's arsenal. (p. 40)

There is sufficient evidence to prove that creativity and entrepreneurship are inseparably linked – creative endeavors by individuals result in more entrepreneurial activities and novel and higher quality products, resulting in long-term success. According to John Burch: "The antithesis of the entrepreneur is a person who never loses because he or she never puts himself or herself at risk" (1986: 34). Venturing into the unknown is preferred by most entrepreneurs, which propels them into starting their own organizations rather than enjoying secure, risk-free contractual employment. Entrepreneurial functioning involves working with a less structured, more uncertain set of possibilities and being solely responsible for major decisions. Hence, more risk-tolerant individuals are likely to 'self-select' into entrepreneurial careers.

Victor Kiam, an American entrepreneur said:

Entrepreneurs are risk takers, willing to roll the dice with their money or reputation on the line in support of an idea or enterprise. They willingly assume responsibility for the success or failure of a venture and are answerable for all its facets.

Risk Taking and Decision Making

The success of most enterprises depends on the capability of their leaders to evaluate risks and decide which path to pursue. Uncertainty has two components, risk and ambiguity, and decision makers' ability for tolerance of ambiguity and risk influence their choices. Successful high risk decision makers consistently tend to see more opportunities in risky situations and higher risk preference manifests itself in greater confidence in their decision.

In 1992, Sim Sitkin and Amy Pablo identified three groups of factors that influence a decision maker's choice of a more or less risky response to a problem: characteristics of the individual decision maker, characteristics of the organizational context, and characteristics of the problem itself. Specifically, they discuss nine key predictors of risk behavior – three individual characteristics: risk preferences, risk perceptions, and risk propensity; four organizational characteristics which directly have

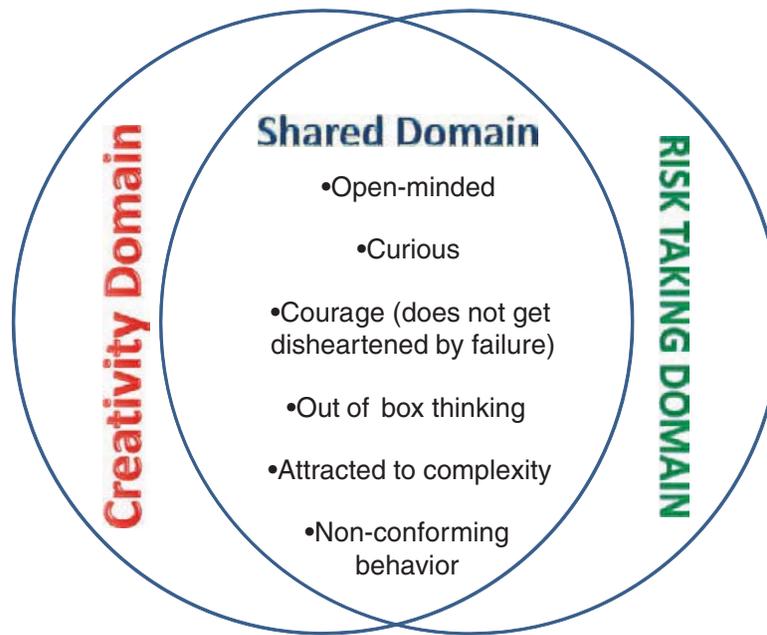

Figure 1 The common factors affecting both creativity and risk taking. (Note: This is not a conclusive list.)

an impact on individual behavior: group composition, cultural risk values, leader risk orientation, and organizational control systems; and two problem-related characteristics: problem familiarity and problem framing. Decision makers are strongly encouraged to take calculated risks, as incorrect decisions may bring a corporation or the entire economy tumbling down, as occurred in the high leveraged risk-taking decisions made at bankrupted companies such as Lehman Brothers and American International Group Inc. – the latter being bailed out by the US government.

To foster risk taking it is of pivotal importance to understand the various factors that have an effect on this construct. Let us begin with the basic debate about whether risk taking is situational or a trait, followed by a brief review of internal factors such as intrinsic motivation, demographics, and external factors such as culture, group dynamics, etc.

Risk Taking – Situational or a Trait?

Scholars have debated whether risk taking is situation-based or a disposition. Some strongly supported the view that it is the situation that determines a person’s risk-taking behavior. Daniel Kahneman and Amos Tversky’s influential Prospect Theory suggests that how a situation is framed will determine individual risk behavior. Another major component of the amount of risk individuals will take is their perception of their abilities in the situation. The greater the ability, the greater the level of risk the individual can reasonably tolerate.

Other scholars, however, have long acknowledged that risky decisions are not based exclusively on rational calculations, but are also affected by individual predispositions toward risk. Thus, a stream of research suggests that risk taking is predispositional rather than simply situational. This position is consistent with the Big Five personality theory (openness to

Table 1 Factors affecting risk taking

<i>Direction</i>	
<i>Positive</i>	<i>Negative</i>
Openness	Neuroticism (emotional instability)
Extraversion	Conscientiousness
Flexibility	Agreeableness
Curiosity	Lack of ability to regulate the self
Courage	Anxiety
Attraction to complexity	Social anxiety
Nonconforming behavior	Irrationality
Intrinsic motivation	Fear
Internal locus of control	Stress/worry
Anger	High importance for security
Thinking outside the box	Elaboration
Originality	Depression

experience, conscientiousness, extraversion, agreeableness, and neuroticism), which suggests that risk propensity is a facet of the trait of extraversion.

Although it may be referred to as a trait, research is still not conclusive and the question remains whether risk taking may be a multi-dimensional construct. There is evidence that other traits and emotions have a positive (increase) or negative (decrease) effect on a person’s risk-taking behavior. As shown in **Table 1**, personality variables such as extraversion and openness have a positive impact on risk taking, while neuroticism (emotional instability) agreeableness and conscientiousness make an individual more risk-averse. Additionally, individual differences in trait anxiety, worry, and social anxiety were each associated with risk avoidance. There is burgeoning interest in understanding the role played by sensation seeking and some emotions which affect risk taking.

Sensation Seeking and Emotions

Researchers identified higher sensation seeking as a personality factor that differentiates risk takers from nonrisk takers. Sensation seeking is defined as the need for varied and new experiences, and incorporates willingness to take risks for the sake of those experiences.

Emotions also play a role in risk-taking behavior. They act as relevant forms of information, indicating the presence of specific threats to be avoided or benefits to be acquired. Affective states are a temporary experience of mood or emotion, while affective traits are dispositions to have such experiences (positive and negative affect). Positive affect and negative affect increase and decrease risk-taking propensity, respectively. Counter-intuitively, an interesting study found that emotions such as fear and anger have opposite effects on risk perception. Jennifer Lerner and Dacher Keltner showed that while fearful people tend to be pessimistic and consequently make risk-averse choices, angry people demonstrated optimistic risk-seeking choices.

Effect of Intrinsic Motivation, Need for Achievement and Self-efficacy

An individual is said to be intrinsically motivated when he or she performs a task due to the sheer fascination of the task itself rather than simply because of its outcomes. Intrinsic motivation is a key ingredient in creativity that has been associated with increased risk taking, which in turn is linked to creativity.

There is a close relationship between risk taking and need for achievement. High need achievers prefer intermediate levels of risk, while low need achievers are more likely to choose extremely low or high levels of risk. Research linking the two constructs can be summarized as follows: Persons high in need for achievement set challenging goals of moderate difficulty, accomplish these goals through effort and skill, take personal responsibility for decisions, and are moderate risk takers.

Self-efficacy refers to an individual's belief in his or her own ability to achieve the task at hand and produce the desired result. People with high self-efficacy are likely to fear failure more and take calculated, as opposed to reckless risks. They are more likely to set themselves challenging goals, expend effort, and persist in the face of adversity.

Other Factors Affecting Risk Taking

Research has confirmed that factors such as gender, age, groups, and culture affect an individual's risk-taking behavior.

Risk Taking Across Gender and Age

Historically women were stereotyped as conservative and risk-averse, as opposed to males who were considered to have higher risk propensity. One of the reasons was that women were forced to fit into the social typecast of being more conservative than males. However, in the late 1980s the social outlook changed with the number of female employees increasing dramatically and a sizeable increase in the number of female entrepreneurs. Consequently, gender differences in risk-taking behavior are assumed to have been comparatively reduced.

The relationship between risk taking and age has received rather less attention, particularly in mature adults. Michael Wallach and Nathan Kogan evaluated risk-taking behavior in college age and older men and women and found that in the older sample both males and females were comparatively more risk averse than their younger counterparts. One of the explanations could be the considerable increase in responsibilities as people get older – marriage, children, and financial problems. These responsibilities deter an individual from taking risks that would have been taken earlier in the person's development. Older individuals were found to have lower achievement motivation compared with younger people. Specifically, in an early study carried out by Heinz Heckhausen, a significant drop in many individuals' level of achievement motive appears to occur only around or after age 50. As was shown earlier, risk taking is closely associated with need for achievement, which shows a steady decline with age. However, stereotyping should be avoided because there are examples of older individuals taking great risks, including Walt Disney who mortgaged his house in order to finish Disneyland.

Risk Taking by Groups

An overwhelming majority of studies provide evidence for understanding the risky shift phenomenon – on average, individuals will privately recommend a greater degree of risk taking after group discussion than these same individuals had privately recommended before the discussion. Roger Brown suggested that group discussion leads the participants to change their individual decisions in the direction of the relevant social-cultural value. This change is explained by the self-image maintenance mechanism, that is, people tend to consider their own decisions to be more consistent with widely held values than the decisions of similar others. When they discover that some other people's decisions are more consistent with these values than their own, they try to maintain their self-image by changing their decision towards the extremes.

Risk Taking Across Culture

Risk taking is a relatively stable attribute of personality that is learned early in life. Research has highlighted the role played by cultural differences that are apparent in the various assessments of risk made by different individuals and groups. For example, in 2000, Melissa Finucane found that among various American groups, whites in general, were less apprehensive about a set of nominated risks compared with nonwhites, with white men being the least apprehensive and nonwhite women the most apprehensive. This disparity could be attributed to the socio-economic advantage experienced by white men making them less risk-averse compared to nonwhites. Another study found that Chinese people were less risk-averse than Americans. This could be attributed to the fact that China and the USA are very different in the individualistic–collectivistic continuum, with China exhibiting a very collectivistic culture and the USA a highly individualistic country. Collectivism refers to a society where social and individual ties are strong, with people being part of strong cohesive groups,

while individualism entails looser ties between individuals, so independence is stressed. Elke Weber, Christopher Hsee, and Joanna Sokolowska explained “collectivism acts as implicit mutual insurance against catastrophic losses” (1998: 174). Furthermore, they pointed out that although people from collectivistic cultures may be less risk-averse to material or financial risks, this will not be true for social risks, as social networks are given immense importance in such cultures.

Another study conducted by Larry Cummings, Donald Harnett, and Owen Stevens, compared risk-taking behavior in five regional clusters with reported scores on a scale of 16–48 (with lower scores indicating risk taking and higher scores depicting risk aversion). Americans exhibited the highest tendency towards risk taking, with the lowest score (31.9) followed by Spain (33.4), Greece (35.6), Scandinavia (35.7), and Central Europe (35.8). In addition to culture, risk taking may be affected by situational differences such as the countries’ present economic, social, and political environment.

Further research is required in the field of risk taking. Researchers have traditionally focused on the psychological and demographic characteristics that discriminate between risk takers and controls; however considerable heterogeneity may exist within risk-taking populations. Moreover, it is important to note that people may not be exclusively classified as risk takers and nonrisk takers but may be selective risk takers, either depending upon the goals’ value or some other factor affecting their choice.

Calculated Risk or Risk Taken on a Whim? A Cautionary Note

Every coin has two sides – hence it is important to understand the flip side of risk taking. Undoubtedly risk taking has its benefits, but there are several factors which must be taken into account before leaping into the unknown. First, the decision should be based on accurate information; past knowledge or prior experience, if any, can be extremely useful in gathering more information. Based on this information time should be spent preparing for the worst case scenario. Other factors include, but are not limited to, the risk-to-benefit ratio, magnitude of impact, whether the effects/consequences of the risk will be experienced by an individual, group, organization or the public, long term and short term impact, etc. When a risk taker takes into account all these factors, basically acknowledging the potential risks of failure, it can be referred to as a calculated risk, as opposed to a complete lack of knowledge of these factors – taking risks on sheer whim.

There are times when risk takers may become the victims of what is known as a ‘halo effect’ – when one characteristic or just one factor dominates all other factors or the person even unknowingly ignores other factors and focuses on only one factor. For example: the enormous size of the Quebec forest, in Canada, was so strong a factor that it seduced the International Telephone and Telegraph (ITT) management into deciding to build a multi-million dollar chemical cellulose mill there without carefully analyzing factors such as political and labor risks in French-speaking Quebec. Lack of formal analysis resulted in a loss of \$600 million on the project.

Additionally it has been found that: (a) past success leads to a willingness to take risks; (b) individuals focus on highly favorable outcomes even if there is less probability of them occurring; and (c) risk-taking propensity is negatively associated with both the time required to reach a decision and the amount of information upon which the decision was based. With respect to risk-taking propensity Ronald Taylor and Marvin Dunnette found that high risk takers make more rapid decisions based on less information, but tend to process each item of information slowly.

Conclusion

In the literature on creativity, one of the most important tasks has been the identification of those personality traits which are characteristic of highly creative people. Risk taking is a distinguishing factor of creative individuals – they are not afraid of the unknown – in fact it is the unknown that arouses their curiosity. They are open to implementing ideas which may have uncertain outcomes. Because of the sheer pleasure of doing things in a unique way the creative individual perseveres and meets challenges head on. A creative individual views the world through the lens of curiosity about the unknown, which frames perception of situational risks, sometimes overemphasizing or underemphasizing them. As George Bernard Shaw aptly said – “The reasonable man adapts himself to the world; the unreasonable one persists in trying to adapt the world to himself. Therefore all progress depends on the unreasonable man.” In today’s world, the risk takers can be regarded as the unreasonable people, who undoubtedly play a crucial role in the progress of humankind. Theodore Roosevelt best answered the question of whether people should be risk takers:

It is far better to dare mighty things, to win glorious triumphs, even though checkered by failure, than to rank with those poor spirits who neither enjoy much nor suffer much, because they live in a gray twilight that knows not victory nor defeat.

Schizophrenia and Psychosis

J Glicksohn, Bar-Ilan University, Ramat Gan, Israel

© 2011 Elsevier Inc. All rights reserved.

Glossary

Delusions False beliefs, including delusions of being controlled by an alien (or, outside) entity and delusions of being persecuted (paranoia).

Executive functions Higher order cognitive functions related to the control, management and allocation of resources such as attention and working memory, and the ordering and completion of tasks, such as in planning and prospective memory.

Negative symptoms Behavioral deficits, including flattening of affect, social withdrawal, poverty of speech, and lack of will.

Positive symptoms Bizarre experiences and beliefs, including hallucinations and delusions.

Psychoticism One of the 'psychosis-prone' personality dimensions, and the third major personality trait (after Extraversion and Neuroticism).

Schizophrenia and Schizophrenic Thinking

Readers of this article – especially those interested in their own creativity – face the uncomfortable prospect that creativity is intricately related to psychopathology. This includes the potential relationship of mathematical creativity with autism, artistic creativity with bipolar disorder, and general creativity with schizophrenia. Such a notion appears in various guises in both the literature and the media: the 'madman in the attic,' the 'mad genius,' the 'sensitive artist,' the 'troubled artist,' the 'deranged scientist,' and so forth. Biographical studies of various eminent individuals – artists, poets, musicians, scientists, explorers – discuss their creativity and their pathology, implying that their productivity comes at a personal price and that there is a genetic basis to both creativity and 'madness.' Thus, from the very outset, one has to consider such Romantic ideas concerning the 'troubled artist,' the notion of deviance – in both the positive (creativity) and negative (schizophrenia) senses – and whether there is a continuum relating these different forms. The present article addresses schizophrenia, psychosis, and creativity. It should be stressed that there are mixed views here: some writers have suggested that schizophrenia and creativity might very well be related, especially given the apparent similarity between schizophrenic thinking and creative thinking; other writers have rejected the notion, arguing that schizophrenics are inherently dysfunctional, and thus cannot be 'creative' in the conventional sense. This article will provide the reader with an overview of the schizophrenia-creativity relationship.

So, what can be said about the notion of the 'troubled artist'? Arnold Ludwig has devoted a book to this issue, based on a sample of roughly 1000 'eminent people,' for whom

extensive biographical information was available. For present purposes, let us consider the incidence of schizophrenia, or rather 'schizophrenia-like psychoses' amongst these, namely "at least one sustained psychotic episode, characterized by auditory or visual hallucinations, delusions of persecution, inappropriate affect, extreme suspiciousness, incoherent communication, bizarre behaviors, or impaired ability to care for oneself while clearly conscious," or being formally diagnosed as suffering from schizophrenia. Schizophrenia, having a prevalence of 1–1.5% in the general population, is reported to appear in 5% of this elite group. If the 'troubled artist' is a poet, then the prevalence rate (17%) is certainly supportive of this notion. This is also the case with respect to composers (10%), but also with respect to athletes (11%) – who can hardly be associated with the Romantic notion. Furthermore, note that if 5% of an elite group are found to be schizophrenic, the reverse side of the issue should surely also be considered: What could the prevalence of creativity amongst schizophrenics possibly be? As Marvin Zuckerman writes:

I believe that anyone who has worked with schizophrenics would dispute the assumption that they are creative. Schizophrenics who have made contributions to the literary or visual arts are rare. The argument hinges on the meaning of the term 'creativity' ...

One must therefore consider whether a definition of creative thinking is homologous with that of schizophrenic thinking. **Table 1** provides a useful comparison of the two. There is certainly a substantial degree of overlap in various qualities of thought, broadly defined. Nevertheless, given that creativity has as a prerequisite the need for sustained logical thinking, and that schizophrenics exhibit a deficit in logical thinking, the

Table 1 Comparison of creative thinking with schizophrenic thinking

<i>Creative thinking</i>	<i>Schizophrenic thinking</i>
Inspiration (i.e., ideas being suggested by 'otherworld' beings)	Thought insertion (i.e., alien thoughts enter one's mind)
Unusual (or, remote) word associations	Tangentiality (i.e., digressing from one idea to another by association)
Bisociation (i.e., joining seemingly unrelated information or thoughts)	Derailment (i.e., unrelated ideas compromise logical thought)

degree to which they can be creative must surely be impaired. The deficit in logical thinking that one encounters in schizophrenia (which some authors have referred to as 'paralogical' or, 'paleological' reasoning), is based on the *pars pro toto* rationale. Thus, consider the following familiar example of the schizophrenic who claimed that she was the Virgin Mary. When asked why she thought that that was the case, she reasoned that that was because she was a virgin. This deficit in logical thinking is in many respects similar to the notion that schizophrenics exhibit a frontal-lobe, or dysexecutive, syndrome, with characteristic inflexibility and perseveration, and a problem in judgment. While faulty logic would certainly impede making progress in *linear* problem solving, one should also consider the notion that by generating a similarity between two entities, there is a transition to nonlinear or bidirectional metaphoric thinking – which is certainly of value in creativity.

Consider the following proverb: *When the cat's away, the mice will play*. The proverb was first coined in the fourteenth century (in French, *ou chat na rat regne*), and one version appears in Shakespeare's *Henry V* (*Playing the mouse in absence of the cat*). What does the proverb mean? One can try to provide a singular interpretation, thus exemplifying *convergent* thinking (e.g., *When no one in authority is present, the subordinates can do as they please*). One could also try to provide as many different interpretations as possible, thus exemplifying *divergent* thinking (e.g., one relating to extramarital affairs, another relating to illegal financial transactions, etc.). While proverbs can thus be used to study creativity they have primarily been used to understand schizophrenic thinking. Consider the following responses made by schizophrenics, appearing in a chapter from more than 60 years ago, wherein the author advocates the use of proverbs for studying schizophrenic thinking: (1) *When there's nobody watching, they do things they wouldn't if the cat were there* (an example confined to a *literal* or *concrete* understanding, indicating an 'impairment in thought' – but one also seen among normal controls). (2) *The last supper of Jesus, all those that kissed the novitia, the covitia. The political world is too much, we can't fight it, we can't see murder* (an example of *disordered* thought: bizarre content, 'complex-determined sexual and religious preoccupations', though one not really concerned with interpreting the proverb, as the author notes). (3) *That means feline absence and rodential job, which has its sources in the nature of the Saviour; divine forgiveness, Heaven and Hell, inscrutability* (which combines a *literal* interpretation with a religious preoccupation).

What is this thought disorder that is characteristic of schizophrenia? As Norman Cameron has suggested, "the schizophrenic patient may reach a level of verbal discontinuity at which his talk becomes useless as an instrument of communication." Schizophrenic thought has been characterized by overinclusion, namely a dedifferentiation between the personal and the general in conceptualization. There seems to be a wider 'sphere of meaning,' a 'fluidity' or 'looseness' of thought – one that certainly indicates ideational fluency, but not focused problem solving that would result in something useful or appropriate to the situation. If one's definition of creativity requires some tangible accomplishment, or novel product having practical relevance, then schizophrenic thought falls far from the target. On the other hand, if one focuses on fluency and flexibility of thought, then schizophrenia remains relevant. As one author has suggested, "creative thinking is distinguished from schizophrenic thinking by a more critical assessment of the products of such thinking."

One recent study has indicated that the *positive* symptoms of schizophrenia (e.g., hallucinations) may be similar to creative production, whereas the *negative* symptoms (e.g., flat affect) may be negatively related to verbal fluency. The term 'schizophrenia' covers various forms of pathology – one major subdivision being that differentiating between paranoid and nonparanoid schizophrenia. Various studies have supported a distinction between paranoid and nonparanoid schizophrenics in cognitive functioning in general, and with respect to creativity in particular. For example, one study reported that paranoid schizophrenics had significantly better verbal IQ, executive functioning on the Wisconsin Card Sorting Test (WCST), and memory for spoken language as compared to nonparanoid schizophrenics. Nonparanoid schizophrenics seem to be more creative than paranoid schizophrenics – at least with respect to one familiar test of divergent thinking, the Alternate Uses Test, assessing fluency, flexibility, and originality of thought. Nonparanoid schizophrenics seem to exhibit divergent thinking, whereas paranoid schizophrenics seem to exhibit convergent thinking.

Note that if paranoid schizophrenics have more 'preserved' cognitive functions (i.e., executive functioning, convergent thinking), then they should not be as impaired in logical thinking as nonparanoid schizophrenics. To investigate this, the authors of one recent study employed a logical reasoning task, comprising two parts: in the first, the participant was presented with five syllogisms, and had to decide for each of these what would be the valid inference; in the second part, the participant was presented with five syllogisms, and had to decide for each whether the inference was logically valid. An example from the first part is the following:

All men are mortal
Socrates is a man

An example from the second part is the following:

All birds have wings
No winged creature is a mammal
No bird is a mammal

The participant's score here is the number of correct answers, ranging between 0 and 10. A group of 12 paranoid

schizophrenics was compared with a group of 12 nonparanoid schizophrenics. All patients were on medication at the time of testing. Exclusion criteria were evidence for dementia and current acute psychosis. The two groups significantly differed in line with expectation, the mean score for the paranoid schizophrenics being five, while that for the nonparanoid schizophrenics was slightly above three.

There is another side of the coin to creativity, and this refers to *rigidity* of thought, namely the tendency to perseverate in the use of mental and behavioral sets (as assessed using, e.g., the WCST). If rigidity and creativity are polar opposites, by definition, then how can schizophrenics be creative, on the one hand, when it is also acknowledged that schizophrenics are more rigid than nonschizophrenic siblings and normal controls? Could they exhibit both forms of thinking? One line of thought suggests that apparently healthy adolescents, who will later on manifest schizophrenia, nevertheless have cognitive abnormalities such as increased variability across intellectual tasks, possibly related to frontal-lobe abnormalities. Such increased variability could reflect a tug of war between rigidity and flexibility of thought during adolescence.

A major issue to consider in studying the relationship between schizophrenia and creativity is that schizophrenics will probably be on medication at the time of testing. How does this impact their test performance? As one author has argued, "in the event of medication, one would expect 'truncated' performance. Free of medication, schizophrenic performance might be considerably more extreme ... with schizophrenics not using the 'same' strategy as normals but employing an extreme form of that strategy." Is there an option of examining schizophrenia-like thought in a normative, non-medicated population? The answer is to be found in the construct of *schizotypy*.

Schizophrenia and Schizotypy

Given the problems inherent in studying creativity amongst schizophrenics on medication, it is natural to consider other phenomena related to the pathology, that are more amenable to experimental research. This is the same line of thinking that one finds in research on normative psychopathy (i.e., 'normal' individuals who might be predisposed to psychopathic behavior, without actually being characterized as being psychopaths). So-called 'psychosis-prone' individuals (i.e., those individuals who might be prone to developing schizophrenia, given the necessary stressors in the environment, who score relatively high on psychosis-related, though normal personality dimensions, such as *Psychoticism* or *Schizotypy*) are of present concern. Common to all such endeavors is the reliance on a *diathesis-stress* concept of the development of psychopathology, namely that the predisposition interacts with environmental stress to result in the behavior and symptomatology observed. The normal personality dimension most clearly affiliated with the construct of schizophrenia is that of schizotypy (which has been viewed as comprising a latent personality dimension – or, rather *dimensions* – for schizophrenia). Before continuing to read, answer the following three questions ('true' or 'false') to get a feeling for the type of personality trait implicated by schizotypy:

1. "Now and then when I look in the mirror, my face seems quite different from usual";
2. "People tell me a lot of lies";
3. "The sound of rustling leaves has never pleased me."

The article on schizophrenia coauthored by David Schulberg and Louis Sass for the first edition of the *Encyclopedia of Creativity* is one of the items appearing in the bibliography to the present article, and provides a useful resource for the literature up to 1999 (Schulberg and Sass, 1999). Research interest since then has been split between that looking at creativity and schizophrenia, and that looking at creativity and schizotypy.

Schizophrenia and schizotypy are both characterized along the same two dimensions – one referring to the positive symptoms (e.g., delusions, hallucinations, etc.), the other to the negative symptoms (e.g., anhedonia, flat affect, etc.) of these phenomena. What do we know about the relationship between schizophrenia and normative (or, dimensional) schizotypy? And what do we know about that between schizotypy and creativity that can shed light on the schizophrenia-creativity relationship? A number of studies have reported a relationship between the positive and negative symptoms of schizophrenia, and their counterparts in nonpsychotic relatives. One study indicated that the relationship was stronger for the negative symptoms than for the positive ones. Other studies have found that positive schizotypy is associated with better performance on measures of creativity (in particular, measures of divergent thinking), while negative schizotypy is associated with better performance on measures of convergent thinking, and with decreased verbal fluency. Visual artists have been found to score higher than nonartists on both positive schizotypy and divergent thinking. One should also consider a plausible difference between artistic creativity and scientific creativity. Thus, while artistic creativity has been related to both schizophrenia and divergent thinking, mathematical creativity has been related to neither (rather, to both autism and convergent thinking).

There is also evidence supporting the notion that schizotypal individuals exhibit right-hemisphere (RH) dominance, or bias, in various cognitive tasks, at the expense of the left hemisphere (LH). This finding comes to further support an argument suggesting that schizophrenics have an impaired left hemisphere – hence have little LH dominance over the primarily verbal products of thought, which flow in a very loose manner, in line with their RH bias. Schizophrenic thought disorder results. Given the affective tone of the RH, the resulting thought is affect-laden, and the schizophrenic experience is essentially *syncretic*. One author has suggested that both the positive symptoms of schizophrenia and positive schizotypy are indicative of impaired LH functioning, while both the negative symptoms of schizophrenia and negative schizotypy are indicative of impaired RH functioning. The RH bias noted for both schizophrenia and schizotypy is seen in imaging studies when such individuals are engaged in a task of divergent thinking (e.g., Alternate Uses). It is a specific right prefrontal cortex (PFC) activation that has been found to be associated with enhanced divergent thinking.

Schizophrenics are more impaired than controls on practically any test of cognitive or neuropsychological functioning employed. Negative symptoms, but not positive symptoms, are

associated with poor cognitive test performance in schizophrenia, particularly on tests of executive functioning (e.g., the WCST) and convergent thinking. One study has found that in contrast with schizophrenics, high-schizotypal adults were just as capable as low-schizotypal adults of identifying appropriate metaphors, suggesting, as the authors indicate, a discontinuity between schizophrenia and schizotypy for the metaphor-recognition problem. This finding also contrasts with those indicating poor proverb comprehension in these individuals (both schizophrenics and schizotypal individuals), which may be interpreted in terms of the difference entailed in recognizing and interpreting metaphors (proverbs).

As with respect to schizophrenics, schizotypal individuals exhibit poor performance on tests of executive functioning. One study has revealed that impaired performance on the WCST was associated with negative, but not positive schizotypy. Another study has indicated that individuals with both positive and negative schizotypy reported higher levels of 'cognitive slippage' than those individuals reporting only negative schizotypy. In other research, schizotypal individuals who were assessed on both verbal and nonverbal executive functions and on nonexecutive functioning exhibited deficits on the measures of executive functions but not on measures of nonexecutive functions. Schizotypy is one major psychosis-related, normal personality dimension(s). The other is psychoticism.

Schizophrenia and Personality

The two primary traits of personality, namely extraversion (E) and neuroticism (N), have been studied with respect to schizophrenics, who seem to score low on E and high on N. They also exhibit, as stressed above, a peculiar or bizarre form of thinking, which might well implicate the third major trait of personality, namely psychoticism (P). A major contribution to the study of schizophrenia and personality has been made by Hans J. Eysenck (1916–1997), who designated P as a 'psychosis'-prone dimension. In Eysenckian theory, P is a dimension along which the various psychoses may be mapped; as Eysenck writes, "close to psychosis [schizophrenia] . . . are behaviours variably diagnosed as schizoid, 'spectrum', or psychopathic . . .". P has been placed at the forefront of contemporary research looking at personality and psychopathology, but also at that looking at personality and creativity. Manic-depressives, for example, who have a clear propensity for creativity, seem to score high on E and, more importantly, high on P.

Eysenck's theorizing regarding P suggests that this is the common underlying continuum for affective disorders, schizophrenia and creativity. A second line of thought suggests that schizophrenic thinking is part of a general continuum of thinking, on which creative thinking may also be mapped. Indeed, as Robert A. Prentky has written, "given the current state of knowledge, it seems highly untenable to conclude that creativity has a greater affinity for manic-depressive illness than schizophrenia or vice versa." The assessment of this major personality trait in schizophrenics should therefore be revealing. To what extent can P be the underlying continuum for both cognitive psychopathology and personality? It is important to stress that while Eysenck views P as indicating

proneness to psychosis, he also views P as indicating proneness to psychopathy. Other authors argue that P is more intricately tied to psychopathy and antisocial behavior than to psychosis. In fact, there is an interesting relationship between psychosis and psychopathy, as revealed by the fact that children born to schizophrenic mothers have elevated rates of psychopathy and elevated rates of criminal records. One author has argued that it might only be paranoid schizophrenics who would be characterized by high levels of P, while schizophrenics presenting negative symptoms should not score high on P.

Be this as it may, P should perhaps not be considered in isolation of another personality trait, revealed by the lie scale (L) of Eysenck's questionnaire, especially given some recent data indicating a negative correlation between P and L, amongst both 'normals' and schizophrenics. The L scale was explicitly incorporated in the measurement of personality within the Eysenckian system so as to assess the degree to which subjects attempt to 'fake good.' It was reported that the items comprised a scale; it was also suggested that in addition to measuring dissimulation, the L scale "also measures some stable personality factor which may possibly denote some degree of social naiveté." A conundrum therefore exists here. If the L items comprise a scale, then how can the same scale measure two separable factors of dissimulation and social naiveté? Further, how can one distinguish these two functions in a given setting? More importantly, given that both factors are, at least partially, situationally dependent, how can one disentangle person and situation in what is evidently an interactive process? A negative correlation between L and P (~ -0.20) has been found. This negative correlation increases somewhat among prisoners (especially, female) and among neurotics (~ -0.30). The interpretation readily adopted by a number of authors here is that high P scorers tend to have low L scores, because they do not mind admitting their undesirable behaviour. High L scorers, in contrast, might "sincerely believe that their socially desirable answers parallel their true behavior. Presumably, these respondents are conscientious and law-abiding individuals." A recent study has further revealed a significant negative correlation between P and L among first-degree relatives of 'affective psychotic' patients ($r = -0.30$ for female relatives, and -0.32 for male relatives), but not for the relatives of schizophrenics ($r = -0.02$, and -0.05 , respectively).

It is worthwhile considering the P–L relationship with respect to both schizophrenia and creativity. One author has argued that "rather than being a sign of 'dissimulation,' the more usual interpretation of the higher Lie scores earned by psychotics is that psychotics, as a class and by definition, are unworldly, disturbed, and erratically functioning individuals no longer seeking or able to conform to societal standards." To this, Hans and Sybil Eysenck replied: "our explanation was that psychotics tend to have high Lie (L) scores, which lowers their P scores below what they would otherwise be, whereas the other groups . . . do not have such elevated L scores." And further on: "Combining scores to get better differentiation not only makes good psychological sense but also gives good differentiation (particularly when the poor replicability of psychiatric diagnoses is borne in mind)."

David Rawlings has commented on the fact that while high P is usually combined with low L, nevertheless schizophrenics

(as a group) tend to have high L (and are also hypothesized to have high P), and bemoans the type of explanation that ascribes such findings "to drugs, to hospitalization, or to other 'secondary' effects of the psychiatric breakdown. This type of explanation is unsatisfactory because it does not explain why the high Ps actually behave the *opposite* to expectation, and does not specify the conditions under which such a reversal is likely to occur." One recent study has indicated that while paranoid schizophrenics do have elevated L scores and corresponding low P scores, nonparanoid schizophrenics have elevated P scores and corresponding low L scores. It thus seems to be a wise strategy to avoid global characterizations, such as 'schizophrenia,' for a more specific category of psychosis, such as the distinction between paranoid and nonparanoid schizophrenia. Evidently, these two groups of schizophrenic patients, are diametrically opposite in the Eysenckian P-L plane.

Following an argument appearing in a recent study, it is of further importance to stress that while low L scores denote a degree of conventionality, it is also possible that part of the relationship between P and creativity is due to the need to be unconventional, or perhaps even to function outside the boundaries imposed by the law. As Eysenck has written, "The association of genius-creativity with P may also serve to explain what would otherwise be somewhat confusing – namely, the proclivity of genius to fraud and deceit ... The range of famous scientists who 'betrayed the truth' ... is immense, ranging from Ptolemy to Newton, from Mendel to Millikan. How can honest, upright citizens descend to such conduct, which would be criminal if indulged in by an accountant or tax inspector?" Personality and cognitive psychopathology are thus intricately related.

Schizophrenia and Creativity

Heinz Werner (1890–1964) marked one dimension of development as that moving from a syncretic level to a discrete one, that is, from a "state of relative globality and lack of differentiation to a state of increasing differentiation." Syncretic cognition entails a dedifferentiation of perceptual qualities in subjective experience, the most predominant example being synesthesia. But syncretic cognition, according to Werner, also refers to "the lack of differentiation between what one dreams and what one sees, as is found in psychosis." Schizophrenic thinking could thus be characterized in terms of this 'primitive' level of syncretic experience. In fact, both creative thinking and schizophrenic thinking could rely on, or have access to, this same syncretic level of cognition. On the creative side, this dedifferentiation would allow for flexibility of perception and thought, as categories or concepts dissolve, become entwined and in general interact. On the schizophrenic side, this would entail some 'prelogical,' 'paleological' or 'looseness' of thinking, which could suggest an incoherence of thought, an impaired mode of thought or a thought disturbance, as discussed earlier.

In one study, both syncretic cognition and symbolic cognition were investigated. Participants were drawn from three groups: schizophrenics, visual artists, and controls. The artists had no psychiatric history; the controls had neither a psychiatric history, nor were actively engaged in visual art. Both

schizophrenics and visual artists were hypothesized to exhibit a greater degree of syncretic cognition than normal controls. Turning to symbolic cognition, a distinction was drawn between metaphor production and metaphor comprehension. Metaphor production was assessed using the *Barron Symbolic Equivalence Test*, comprising 10 symbolic images (e.g., *Tall trees in the middle of a field*). For each item, the participant is required to produce three metaphors or 'equivalent symbolic images.' The number of admissible verbal responses (i.e., those that match structurally or functionally the given metaphors) provides a measure of ideational fluency. A second measure pertained to an evaluation of the participant's creativity (originality), whereby each verbal response was rated on a five-point evaluative scale, with a test score being the mean of these evaluations. Metaphor comprehension was assessed using Gorham's *Proverbs Test*, comprising 15 proverbs (e.g., *Don't cry over spilt milk*). For each item, the participant is required to choose one of three possible interpretations listed for each: a concrete one (rated 0), a second which is more abstract, but still not quite related to the conventional meaning of the proverb (rated 1), and the third which is both abstract and presents the conventional meaning of the proverb (rated 2). The participant's score is the sum of these 15 ratings.

Both ideational fluency and originality were found to be similar for schizophrenics and controls. Thus, metaphor production was not impaired amongst schizophrenics. In contrast, proverb comprehension was impaired in schizophrenia, as one would expect. Both schizophrenics and visual artists were found to exhibit a high degree of imagination and absorbed involvement. Visual artists, as opposed to the schizophrenics, were able to exhibit both a vivid imagination and a high degree of metaphor comprehension. Thus, schizophrenics simply do not have the tools to both constrain their thought and to enable successful hierarchic integration of their thinking within a coherent conceptual system. Nevertheless, given that they do not seem to be impaired in metaphor production (either in terms of fluency or originality), they could well exhibit creative thinking – though perhaps not one constrained to practical use.

Finally, one should consider the preoccupation of schizophrenics with metaphor. One notion in the literature is that the schizophrenic experience itself is 'permeated with metaphorical meaning.' If schizophrenics engage in metaphoric thinking to understand and describe their unusual experiences (positive symptoms), then their delusions might well conform to the following equation:

$$\text{Unusual Experience} + \text{Metaphoric Thinking} = \text{Delusion.}$$

As one author has written, "the patient is delusional because he or she is actually experiencing anomalies that demand an explanation." Other equations appearing in the literature are the following:

$$\begin{aligned} \text{Unusual Experience} + \text{Normal Logic} &= \text{Delusion;} \\ \text{Normal Experience} + \text{Abnormal Logic} &= \text{Delusion.} \end{aligned}$$

Each of the latter options has its problems. The notion that schizophrenics apply normal logic is contraindicated by their clear deficit on a logical reasoning task. The notion that schizophrenics apply abnormal logic is contraindicated by

the familiar fact that normal individuals also exhibit faulty logic in judgment, decision making, and reasoning. If the schizophrenic were able to become absorbed in solving a problem not intimately related to his or her own subjective experience, then an engagement with metaphoric thinking would certainly be predictive of creativity. This is worthy of further research.

To conclude: The present article has considered the relationship between schizophrenic thinking and creative thinking, providing an overview of the major views here. Positive symptoms of schizophrenia and positive schizotypy seem to be related to both creativity (divergent thinking) and an impaired LH functioning, while negative symptoms and negative schizotypy seem to be related to both convergent thinking and an impaired RH functioning. The role of metaphoric thinking in schizophrenia should be further considered in future research.

ROBERT SCHUMANN was a German pianist, founder and editor of the Neue Zeitschrift für Musik (New Journal for Music), a conductor, and a composer. His published works range from miniature pieces for piano to virtuoso works on a grand scale. He composed powerful symphonic works and song-cycles of great depth and beauty. He wrote compelling chamber music for various instruments, oratorio, and operas. Schumann was one of the great figures of the Romantic era, a contemporary of Mendelssohn, Wagner, Chopin, Verdi, and Liszt, composers of such diverse style yet all born within four years of each other in the German, Polish, Italian and Hungarian principalities. However, Schumann fought against serious mental problems all his life. While he experienced surges of creativity, both musical and literary, his recurring depressions, inner turmoil, and episodes of madness led to a suicidal attempt to drown himself in the Rhine and a final incarceration in an asylum near Bonn.

Background

Robert Schumann was born June 8, 1810, in the small town of Zwickau, Saxony, halfway between Dresden, the artistic court capital, and Leipzig, the scholarly center of Germany. Robert's mother, Johanne Christiane Schnabel, was the daughter of a military surgeon. His father, August Schumann, the son of a Lutheran minister, was a prolific author and founder of Schumann Brothers Publishing Company. The year Robert was conceived, 1809, was a stressful time as August was mourning the death of both his father and his newborn daughter. August and Johanne Christiane had a daughter

nine months after their marriage, then three sons in 1799, 1801, 1805, followed by a baby girl who was either stillborn or died soon after birth, a year before Robert was born. His mother, close to menopause and severely depressed by the loss of this infant daughter, may have wished for another girl. Schumann's father was also prone to melancholia and suffered from chronic abdominal problems.

In 1813, the province of Saxony experienced famine and devastation. A typhus epidemic broke out and eliminated 9% of the population. Schumann's mother was one of the survivors. As she had to be quarantined, Robert was separated from his mother for 2½ years and was placed with a surrogate mother. In his autobiography written at age 15, Schumann vividly recalled nights fraught with fear and nightmares.

Schumann began music lessons at age 7 with a church organist, Johann Gottfried Kuntsch (1775–1855). He soon assimilated all the rudiments of harmony and keyboard technique this teacher possessed. Schumann's creative awakening was manifest as early as 1817–1818 in both literary and musical compositions.

Florestan and Eusebius—Literature or Music

Schumann was an isolated child in a middle-class family with no tradition for musical professionalism. He was endowed with a wonderful talent for improvisation, which he used to capture people's manners and idiosyncrasies. Robert's education was enhanced by his father's private library, which contained approximately 4000 books, a definite stimulus to intellectual development. He discovered a passion for literature comparable to his love of music. It created a lasting conflict, trying to achieve verbal mastery to please his father while striving to communicate with his mother through musical sounds. This duality was later expressed when, at the age of 21, he created two imaginary companions, "Florestan" representing Schumann's masculine, outgoing self, and "Eusebius" the shy, withdrawn, and sensitive alter ego.

Two traumatic events contributed to Schumann's first serious depression at age fifteen, the death of his sister followed by that of his father. Schumann's sister, Emilie, 14 years older than Robert, suffered from a chronic skin disease as well as from emotional problems. It is believed that she either drowned herself or jumped from a window. This seems to have precipitated in Robert an inescapable "longing to throw

myself into the Rhine.” Later, in his early twenties, Schumann attempted to leap out of a fifth-story window, which led to a fear of heights as a possible self-protective mechanism. In August 1826, 10 months after the suicide of his sister Emilie, Schumann’s father died suddenly at the age of 53. As a way to alleviate his sorrow and emulate his father’s literary proficiency, Schumann began to keep daily records in his diary. He also wrote poetry and novels, but most of these adolescent works remained unfinished.

Jurisprudence and Debauchery—Student Years in Leipzig and Heidelberg

In 1828, Schumann decided to join his friend Emil Fleischsig at the University of Leipzig. After much inner torment, he chose to go into jurisprudence, despite thinking it cold and dry. In this setting Schumann, shortly before his 18th birthday, experienced his first dissociative attack. “I seemed to be losing my mind: I did have my mind, yet I thought I had lost it. I had actually gone mad.” This momentary disorganization could have been caused by overwhelming stress. At 18, he discovered the euphoric state of alcoholic intoxication and got “high” not only from alcohol but from other substances such as nicotine and caffeine. Schumann became aware of inner voices, or auditory expressions of diverse emotions often of a sensuous nature. Homosexuality is a frequent topic in his diary.

In Leipzig, Schumann wrote songs based on poems by Justinius Kerner (1786–1862). He was more and more drawn to music and to the charismatic piano teacher, Friedrich Wieck. This well-known pedagogue guaranteed his piano method, citing as best evidence his highly proficient 9-year old daughter, Clara, whom he wished to mold into the world’s foremost pianist. Clara was an unusual child who did not use words until the age of four. When she first encountered Robert in 1828, the childish 9-year old was obviously smitten by the handsome yet taciturn 18-year old pianist.

Schumann’s lessons with Wieck were not altogether satisfactory. Wieck was a demanding task-master who expected the aspiring pianist-composer to practice hours of technical exercises. The recalcitrant student’s strange way of composing is vividly described by his roommate Fleischsig, “He always puffed on cigars, and the smoke irritated his eyes . . . he liked to whistle the melody of the songs, or rather hum them through his lips, and whistling with cigar in mouth was just about impossible.” In 1829, Schumann’s most daring composition was a quartet for piano and strings, which he performed in weekly chamber music evenings. Discussions and animated conversations followed the performances, but Schumann did not participate. His lack of verbal communication often perplexed his colleagues.

To alleviate his restlessness and recurring bouts of depression, Schumann decided to move to Heidelberg. In letters to his mother, he expressed growing concerns, “My lodgings face the insane asylum on the right and the Catholic church on the left, so that I’m really in doubt whether one is supposed to go crazy or become Catholic.” Though he wrote glowingly about his law studies, in truth he was relying on drinking beer to cope with loneliness and frustration. Twice he fell asleep with a cigar, setting his bed on fire.

Early Piano Compositions—Return to Leipzig

After vacationing in Italy, Schumann’s motivation to study law seemed to have totally disappeared. Piano playing constituted his main occupation, and improvisation never ceased to elicit his peer’s admiration. Young Schumann did best as a composer of miniature pieces which he appropriately called “*Papillons*” (*Butterflies*). Tonal analogues between words and music will be found in several of Schumann’s later compositions. This work’s brilliant virtuoso style may reflect Schumann’s way of playing at the time. He may have changed the tonality of his “Tocatta” to make the double-notes and stretches easier, for he later acknowledged numbness in a finger of his right hand, a psychophysiological problem which would hamper and finally destroy his career as a piano virtuoso. Deeply perturbed, sounds haunted him during the night creating auditory hallucinations which would become an inherent part of his lifelong battle with madness. For the first time on March 18, 1830, he admits to hovering in a suicidal frame of mind, “longing to throw myself into the Rhine.”

Schumann, dissatisfied with his musical progress though recognizing his superiority over Heidelberg pianists, wished to renew contact with his former teacher Friedrich Wieck. He pleaded with his mother to intercede with Wieck on his behalf. Music seemed his only mode of salvation. The response from Wieck not only surprised Schumann’s mother but added to her confusion as to her son’s chosen career, “I give my pledge to make your son Robert, with his talent and his fantasy, into one of the greatest living pianists within three years.”

With limited means, Schumann relocated to Leipzig, where Wieck rented him space in his large house and placed him on a 6-month probation. Schumann diligently practiced 6 to 7 hours a day, although he felt depressed and constrained in this environment. Wieck’s alternating crude contempt and exorbitant praise toward Schumann and his cruel behavior to his children were most disturbing.

Music Critic—Hand Problem

Schumann’s two imaginary friends, Florestan and Eusebius, gave voice to musical as well as literary ideas. A product of his vivid imagination, they are suggestive of a latent psychotic tendency. As he neared his 21st birthday, music was relegated to second place and literature absorbed him more and more. He relished the works of E. T. A. Hoffman, and wrote poetry in the style of Schiller and Petrarch. Schumann began his career as a music critic with a startling and now famous review of Chopin “Hats off, Gentlemen, a Genius!” which was published by the *Allgemeine Musikalische Zeitung* in December 1831. His novel approach to music criticism aroused much attention from his readers while composers gained publicity and greater recognition from Schumann’s writings.

Though Schumann made progress in his creative work—studying counterpoint, publishing his writings—a regressive pull toward states of terror and confusion held him back and contaminated his level of interaction with people. His speech was scant and constrained. It is interesting to note that Schumann’s hand problem coincided with the rising fame of his young

friend, Clara Wieck. Schumann possibly had a case of tendonitis, and perhaps nerve entrapment, a result of long hours of strenuous practice, known as overuse injury which often afflicts musicians who overtax their musculature. This resolved his conflict between becoming a pianist or a composer. As his state of mind improved, he composed a set of *Intermezzi* (opus 4), published in 1833. While improvising at the piano he kept playing with a four-note sequence, C F G C, a theme suggested by Clara which he incorporated in his *Impromptu on a theme by Clara Wieck* (opus 5). This marked the first of many musical references to Clara in his compositions.

Acute Breakdown

In July 1833, Schumann contracted malaria, had to be quarantined, and lost a good deal of weight. His letters show an unmistakable yearning for Clara, “a chain of sparks now attracts us.” This was the beginning of a long, romantic, and stressful relationship for both Schumann and Clara. It alienated Schumann from Wieck for years to come. While Schumann lay ill with malaria, his brother Julius was dying from tuberculosis. Schumann could not overcome his fear of death and did not even go home when his brother died, in August 1833. He withdrew into social isolation, immersing himself in creative work. In a selftherapeutic manner, he decided to consolidate all his previous writings in what would become a New Journal for Music, *Neue Zeitschrift für Musik*. Instead of the usual introspective entries in his diary, he began writing for the public at large. This journal gained universal recognition.

Two months later the death of Rosalie, his favorite sister-in-law, shattered his precarious equilibrium and caused an acute breakdown. Suicide and madness were his constant thoughts. Fortunately, another regenerating idea lifted him out of his depression, the founding of the Davidsbund, a fraternity of artists and musicians.

Romantic Relationships

As Clara Wieck’s devotion to Schumann intensified, her father’s vigilance escalated. He sent his daughter to Dresden for 6 months to study composition. Meanwhile, Schumann was ostensibly attracted to another of Wieck’s students, Ernestine von Fricken. Clara took notice of this affair when she returned from Dresden, feeling sad and disheartened. Ernestine’s father, Baron von Fricken, was an amateur flutist, and sought Schumann’s advice on a *Theme and Variations* he had written. Schumann gallantly incorporated the Baron’s theme in a magnificent piano work which he called *Etudes Symphoniques* (opus 13). This simple theme, beautifully harmonized, is succeeded by numerous etudes or variations suggesting orchestral instruments. The scope and texture of this gigantic work is reminiscent of a large orchestra, and the tonal resources of the piano are used by Schumann in ways previously unheard of. It remains one of the most astounding musical compositions of the 19th century.

After introducing Ernestine to his mother in Zwickau, and even though Frau Schumann clearly favored Clara, Schumann gave an engagement ring to Ernestine. However, when the

Baron approved the wedding plans, Schumann bluntly rebuked her. This was another manifestation of his ambivalence toward the women he loved. It has often been thought that Robert rejected Ernestine after the disclosure of her illegitimacy. In reality, Schumann abandoned Ernestine long before he found out that she was an adopted, illegitimate daughter, and might not become the baron’s heiress. She remained a loyal and helpful friend during Schumann’s subsequent legal battle over another woman, five years later.

Schumann became the sole proprietor and main contributor of the now biweekly publication *Neue Zeitschrift für Musik*. During this period he created some of his most important musical works including his *Carnaval* (opus 9), a work of impressive originality and immediate appeal. Schumann had hoped that Clara would love and play his *Carnaval*, but she maintained a cool distance until his affair with Ernestine ended. Schumann noted in his diary, “disengagement from Ernestine, beautiful hours in Clara’s arms.”

Separation and Creativity

Deeply alarmed by Schumann’s change of affection, Wieck hurriedly dispatched Clara to Dresden in early 1836. An exchange of letters was futile, as Wieck intercepted and eliminated all of their correspondence. Shortly after his mother died, Schumann went to visit Clara during her father’s absence, and both declared their loyalty and desire never to be separated from each other. Schumann began to picture Wieck as a future benevolent father-in-law. This was not a role Wieck intended to assume. On the contrary, he threatened to shoot Schumann if he came close to his daughter. Clara, the submissive child-pupil not yet 17, obeyed her father for a year and a half. She did not perform Schumann’s works in her recitals, and there was total silence until August 1837. Schumann, deeply hurt, intensified his allusions to her in his compositions, quoting her own themes, using letters of her name in descending patterns, transforming thoughts into tones. This resulted in the birth of four transcendental works conceived in a period of great upheaval, the *Sonatas* (opus 11 and 22), *Fantasie* (opus 17), and *Grand Sonata* (opus 14).

Sustained by his faith in the value of these last works, Schumann hoped that Wieck would finally acknowledge his merit as a composer and potential son-in-law. On Clara’s 18th birthday, September 1837, Robert gathered the courage to send his marriage proposal to her father who responded in negative and cruel terms. At the height of despair, Schumann produced another masterpiece, his most autobiographical composition, the *Davidsbündler Dances* (opus 6), which are individually signed Florestan, or Eusebius, or both. Schumann attached a motto on the title page:

At all times
Pleasure and grief go together
Keep faith in pleasure, and
Meet grief with courage.

At age 27, Schumann finally entered the road to maturity, and now he wished to pursue this road with his betrothed. During Clara’s absence, Schumann reviewed as music critic no less than 81 compositions for his *Review of Leipzig’s Musical Life in*

the *Winter of 1837–1838*. His *Phantasiestücke (Fantasy Pieces)* (opus 12), for piano, have a remarkable structural symmetry and soon became favorites of Clara who often performed them to great acclaim. After which Schumann created *Humoresque* (opus 20), *Novelletten* (opus 21), *Kinderszenen (Scenes from Childhood)* and *Kreisleriana* (opus 15 and 16), *Faschingsschwank aus Wien (Carnival of Vienna)* (opus 26), and *Nachtstücke (Night Pieces)* (opus 23). He left Vienna on April 5, 1839 and arrived in Zwickau four days after his brother Eduardo's death.

Legalistic Dissentions—The Fight for Clara

Friedrich Wieck, writing secretly to a good friend of Clara in Paris, disclosed plans to instigate legal proceedings against Robert and Clara. Using his legal background, Schumann prepared an affidavit. He would request legal permission to marry Clara if Wieck persisted in his refusal to settle out of court. After unsuccessful attempts to negotiate, Schumann filed his complaint on July 16, 1839.

In the courtroom, Clara was quite distraught and rather sympathetic to her father. Schumann escalated his defense, and obtained documents from the town council and local police asserting his good, honorable and decent citizenship. When the court reconvened, all charges were dropped except that of drunkenness.

Songs and Poetry

After a decade of writing essentially music for piano solo, Schumann embarked on a year of song writing of the highest caliber, placing him alongside his revered Schubert. The literary skills Schumann acquired from his father could flow comfortably with the sensitivity for vocal sounds nurtured by his mother. Schumann continued to express both his romantic genius and his emotional disturbances through his *Lieder*.

His first *Song-Cycle Liederkreis* (opus 24), reflect Schumann's fears, dreams, and melancholic state. The next cycle *Myrthen (Myrtles)* is a collection of 26 *Lieder*, one for each letter of the alphabet, mostly dealing with brides, grooms, flowers and marriages, intended to be a wedding present for Clara. After a brief reunion in Berlin, where Mendelssohn sang Schumann's songs accompanied by Clara, another lengthy separation from Clara gave birth to the most celebrated songs, the sublime *Liederkreis* (opus 39) and the *Dichterliebe* (opus 48), written in isolation. While Schumann's pen continued to produce an array of incredible songs, such as *Frauenliebe und Leben (Woman's Love and Life)* (opus 42), Wieck was on the verge of capitulating. When he finally renounced further legal proceedings, Schumann was jubilant.

Marriage and Symphonies

Awaiting the verdict of the high court in Dresden, Schumann chose the day before Clara's 21st birthday, September 12, 1840 for their marriage in the village church of Schöenefeld, near Leipzig. They began writing a household and marriage diary together and collaborated on *The Springtime of Love* (opus 37).

Soon Clara became pregnant, and this incited Robert to a flurry of creative activity. In four days he wrote the first draft of his *Symphony in B-flat major (Spring)*, (opus 38). A month later, the score was completed. The premiere of this exultant symphony, March 31, 1841, was an immediate success and later that year, their daughter, Marie, was born on September first.

In 1842, Schumann began composing three string quartets in a frenzy of enthusiasm. Clara followed suit by becoming pregnant again. This may have inspired Schumann to create one of the pivotal chamber music works of the 19th century, the grand *Quintet for Piano and Strings in E-flat major* (opus 44), followed by *Quartet for Piano and Strings* (opus 47).

Looking back on Schumann's productivity since his marriage, the years 1840 through 1843 are most impressive for their musical creations, notwithstanding other significant responsibilities such as a newspaper to publish, and a family to provide for. On July 24, 1843, Elise, their second daughter was born. She was christened on the day that Schumann started teaching at the new Conservatory of Music, founded by Mendelssohn in Leipzig. His teaching was unsuccessful and lasted less than a year. The end of 1843 also marks the invitation from Wieck for a reconciliation in Dresden.

Travels to Russia—Relocating in Dresden

In 1844, Schumann and Clara embarked on what would be a triumphant concert tour of Russia for Clara, but a demeaning experience for Schumann. He was mainly acknowledged as Clara Schumann's husband. At social events, he remained silent and reserved. Schumann was a poor traveler and 4 months of horrendous schedules soon affected his moods. He was incapable of working under those stressful conditions. Following the trip to Russia, Schumann experienced one of his most severe depressions. A move to Dresden seemed advisable and Schumann, no longer interested in publishing his *New Journal*, decided to sell it. In December 1844, the Schumann household moved to Dresden. Schumann consulted a physician to treat his "violent nerve attacks," also his blurred vision and nearsightedness.

A third daughter, Julie, was born on March 11, 1845. As the voices increased in his home, Schumann wrote more and more contrapuntal music, including six "Fugues" based on the name of Bach (opus 60). Though Schumann lived only five years in Dresden where he had to endure daily visits from "the old man" (Wieck), and despite a massive depression, this was one of his most productive periods. His social demeanor, however, was deteriorating and he became more and more withdrawn. There was a halt in musical inspiration until shortly before Christmas when new ideas surfaced in Schumann's mind with great speed and intensity. In three days he completed the first movement of his C major *Symphony*. Afterward, Schumann felt much better.

In February 1846 Schumann's first son and fourth child, Emil, was born. Four days later, Schumann attempted to orchestrate his symphony; it progressed at a snail's pace. The full score was completed by the end of the year, despite a constant ringing in his ears. Concerts in Vienna, Prague, and Berlin were poorly attended and Schumann's conducting was so frustrating for the musicians that Clara rehearsed them from the piano.

Upon returning to Dresden in 1847, Schumann's creative thoughts turned to opera. The orchestral overture to *Genoveva* is one of Schumann's most successful works. However, the death of their 16-month-old son, the fatal collapse of Mendelssohn's sister while playing the piano, followed by the loss of their friend and mentor, Felix Mendelssohn, plunged both Schumann and Clara into a deep state of mourning. Nevertheless, Schumann was able to compose two *Piano Trios* (opus 66 and 80), interrupted by the birth of another son, Ludwig, on January 20, 1848.

In 1849, an abundance of works emerged from Schumann's creative genius, instrumental works for clarinet and piano, horn and piano, horns and orchestra, violoncello and piano, vocal works for chorus, women's voices, vocal quartet and piano, and *Song Album for the Young* (opus 79), a counterpart to his pianistic *Album for the Young*.

Political Upheaval—Escape from Dresden

In 1848 and 1849 political uprisings in Germany aroused Schumann's feelings and may have contributed to what was a most prolific period. He wrote many patriotic songs for chorus and organized a choral society. When the revolution broke out in Dresden, Schumann and Clara were forced to hide in the house until they managed to escape through the garden gate with only their eldest daughter. Later, Clara, 7 months pregnant, walked several kilometers in open fields during the night to rescue the other children. Concealed from the upheaval, Robert composed *Five Hunting Songs* (opus 137) for double male chorus and four horns, and "Motet" (opus 93).

On June 12, the Schumann family headed back to Dresden where soon Schumann wrote sketches for the *Requiem for Mignon* (opus 98b) from poems by Goethe. July saw the completion of three scenes for his Faust opera and the birth of their sixth child, Ferdinand, and in August Schumann completed *Four Songs for Soprano and Tenor* (opus 78), which included a tender lullaby. In September, Schumann wrote *Twelve Four-Hand Piano Pieces for Little and Big Children* (opus 85) closing with Schumann's favorite, a hauntingly beautiful and hushed expression of nocturnal repose, "Evening Song."

As this incessant flow of lyrical and powerful music continued, Schumann's fame was on the upsurge.

Düsseldorf—The Declining Years

In November 1849 Schumann was offered and accepted the post of music director in Düsseldorf. The Schumann family was warmly welcomed to Düsseldorf and serenaded by the Choral Society. In the midst of directing orchestral and church concerts, Schumann managed to write one of his most compelling works, the *Concerto for Violoncello and Orchestra* (opus 129), followed by his *Rhenish Symphony no. 3* (opus 97). Perhaps as an antidote to his unrewarding work with his orchestra, his interests shifted to chamber music. In 1851 he wrote *Fairy-Pictures for Viola and Piano* (opus 113), *Sonatas for Violin and Piano* (opus 105 and opus 121), and *Trio for Violin, Cello, and Piano* (opus 110). He also produced new music for

the piano, five four-handed pieces for children, and wrote 23 songs plus a number of longer choral works. If these were declining years, they were far from unproductive as Schumann created one-third of his total compositions in Düsseldorf. His ineptness as a conductor became more apparent, and the musicians began voicing their discontent. Another daughter, Eugenie, was born on December 1, 1851.

While vacationing in the Rhineland, and following a strenuous walk in the mountains, Schumann fainted, and a physician was consulted. Dr. Müller, also a director of the Music Society, advised Schumann to restrict his conducting and allow his assistant Julius Tausch to direct more concerts. He recommended 18 riverbath treatments in the cold Rhine. In mid-September 1852, the Schumanns moved into a spacious townhouse, the last residence they shared in Düsseldorf.

Brahms, Joachim, and the Schumanns

On September 30, 1853, a young man of 20, blond and blue-eyed, stood like an apparition on the threshold of the Schumann home. His name was Johannes Brahms, and he came from Hamburg for a brief visit that extended to 1 month. Schumann and Clara were both immensely taken by the angelic young man and his creative talent. In November 1853, Schumann, exhausted and demoralized, relinquished all of his responsibilities as music director. On the brink of a breakdown he was able to produce the *FAE Sonata* for Joachim, a set of *Fairy Tales* (opus 132), and *Songs of Early Morning* (opus 133), inspired by Brahms.

On their last journey together, in Hanover, the Schumanns wanted to visit their "two young demons" Joachim and Brahms. While Clara had great success playing at the court of George V, Schumann's new works for violin, the *Fantasy* and the *Sonata*, were badly criticized and contributed to "anger and restless nights." They were back in Düsseldorf in February 1854. On February 12, constant hallucinations of glorious and unearthly music threatened to "destroy his mind," wrote Clara. In his psychotic delirium Schumann wrote variations on a theme that he believed Schubert had sent him.

Descent into Madness

On February 26 Schumann, fearing he might harm Clara, suddenly announced that he had to go to the insane asylum. The next morning, a worried Clara pleaded with Schumann not to leave her. While consulting with two physicians, she asked their 12-year-old daughter, Marie, to sit with her father. The child, not realizing how sick her father was, let him leave for his bedroom. Schumann slipped out of the house unnoticed, threw himself into the Rhine River. The disoriented and water-soaked Schumann was forcibly brought home and five days later, on March 4, 1854, Schumann entered a private asylum in Endenich, near Bonn. This separation from home and family would last 2½ years until his death. Clara, who was in the late stage of her ninth pregnancy, gave her husband a bouquet of flowers for this last journey. She never saw him again until two days before he died.

Obscurity and Darkness

Few friends visited Schumann at Endenich except for Joachim and Brahms. While Schumann was hospitalized, Clara gave birth to their eighth and last child, a boy called Felix in memory of Mendelssohn. Missing the stimulating presence of his family, Schumann hallucinated an imaginary community of his own. In a deplorable psychotic state, Schumann declined rapidly. He became bedridden and refused to eat, and was unable to control his twitching limbs. On July 29, 1856, Schumann took leave of this world.

An autopsy was performed by Drs. Richarz and Peters with inconclusive findings. The limitations of brain dissecting technique in 1856 made it difficult to affirm if Schumann suffered from temporal lobe epilepsy, syphilis, or some other organic disease. However, no inflammatory cells are mentioned. The medical reports of Schumann's last years in the mental institution, previously thought to have been lost or secretly guarded, have been made available in January 1994 by Professor Reimann. The notes written by Dr. Richarz emphasize the decline of Schumann, his violent behavior and loss of control. The report mentions the composer's belief in the destruction of Düsseldorf, his ordained burning in hell, his being poisoned and his infection with syphilis in 1831. Delusions, hallucinations and lucid observations were noted by Dr. Richarz, as well as the

patient's burning of letters from his wife, which he denied. According to the research of Dr. Peter Ostwald, the most comprehensive diagnosis for Schumann's psychiatric illness is that of "a major affective disorder." His extreme mood fluctuations stemmed from hereditary as well as environmental factors. A "narcissistic personality" describes other aspects of his disturbance—isolation, divided self, and withdrawal. In analyzing the problems leading to his hospitalization, the *schizo-affective disorder* is most probable. These are simply words to describe an illness, but we must look to the sublime music of Robert Schumann to do justice to the 19th century's greatest tone-poet, a quintessential romantic who transcended the tragic events of his life.

Hearing is said to be the first sense to emerge during embryonic development, while sounds are the first sensory stimuli to permeate the small child's perception of its world. A like process apparently unfolds each morning when we ascend from sleep to wakefulness. Before sounds surface into conscious awareness, they are perceived as vague physical-emotional sensations. Thus, ascending one morning from a night's sleep and dreams my first impression of the outside world was music. It conveyed a pleasurable sensation of solidity and yet stimulating freshness. A moment later a voice from the wireless at my bedside table revealed the name of the composer: Clara Schumann. It was the first movement of her piano concerto, opus 7. I pondered on the seemingly incompatible elements of the music, conveying at the same time order and novelty: creativity anchored, as it were, on firm ground whilst roaming unknown territory.

Clara Schumann's entire production comprises about 60 works. She composed mainly for solo piano – about 20 pieces – and lieder – about 25 pieces. A piano concerto (opus 7), three preludes and fugues (opus 16), one trio for piano, violin, and cello (opus 17), and three romances for piano and violin (opus 22) add to the picture. She never ventured to write larger compositions, like symphonies; this was left for her husband Robert Schumann to accomplish, even though they started out together, inspiring and encouraging one another. Soon, however, her reputation as a concert pianist surpassed that of her standing as a composer. After her death in 1896 her compositions were generally ignored whereas Robert Schumann became one of the leading composers of Romanticism. Nonetheless, in our time Clara Schumann's compositions are held in high esteem; her piano concerto, for instance, being evaluated in *The New Grove Dictionary of Music and Musicians* (2001) as "... a dramatic, innovative work, a record of her ... virtuosity and independent musical thinking" and her compositions generally as "creative." An interest in her work was revived in the 1970s and has grown steadily thereafter as have broadcasts, concert performances, and the discography of her works.

Recently, there has been an increasing interest in Clara Schumann's life and work, particularly by musicologists interested in gender issues. To what extent, if any, they ask, have the musical talents of gifted women been stifled by the conventional expectations of their time of what women could accomplish, by family demands, or by those women's internalized limitations, having accepted society's constraints as their own? There are a number of women whose life and work provide fertile ground for analysis of this question. Besides Clara Schumann, there are women such as Maria Anna Mozart (Mozart's older sister), Fanny Hensel (Felix Mendelssohn's sister), or Alma Schindler (whose first husband was Gustav Mahler). Clara Schumann's life is of special interest to researchers because there is extensive documentation of her life and career (see Reich's publication of 2001). An essential source

of information are the large number of letters available, of which the most informative are those exchanged between herself, her father, her husband, and Johannes Brahms, a close friend and supporter for more than 40 years. Even a superficial examination of these letters is revealing as to how her relationships with those close to her, particularly her father and her husband, influenced her development as child prodigy, woman, concert pianist, and composer.

In the nineteenth century, musical education was a normal part of many middle-class women's upbringing. Being able to play the piano and sing at dinner parties was considered particularly appropriate since it agreed so well with that virtuous and modest appearance supposed to befit the female sex in general and a refined woman in particular. This view of the educated woman included the position, or predicament, of being under her father's or husband's custody. The question arises whether a woman raised to take on a subservient role would be inclined to compose music of any originality, an endeavor that would seem to require some assertiveness and autonomy of mind.

Clara Wieck was born in 1819 in Leipzig, which was at that time an important musical center. She spent her first years in a family torn by conflicts between her parents, who divorced when she was five. Her mother, Marianne Tromlitz, was a soprano soloist and skilled pianist. Her father, Friedrich Wieck, was a piano teacher and dealer. After the divorce, Clara and her two younger brothers lived with her father. Her father was known as a competent and innovative piano teacher but also as a man prone to tantrums. He was self-centered, relentless, and uncompromising. Wieck insisted that his pupils devote several hours daily to their piano practice and that they learn everything by heart, so as not to be distracted by looking at notes. He emphasized the importance of "a pure, precise, smooth, clear and elegant touch" aimed at making the keyboard "silent" in itself, so that the music should materialize, much like the artist's brush not being evident when one views a painting, one would assume. Wieck also required his pupils to write small compositions from an early age; at the time, this practice was quite unorthodox. He was determined to make Clara his top pupil, a virtuosa, proof of his outstanding capacity as a teacher. From the time she was five years old, playing the piano was Clara's main occupation, with little time left for anything else. It is rather an understatement that she was deprived of a normal childhood and youth.

When Clara had learned how to write, her father gave her a diary where he used to insert entries in her name – usually about her (alleged) views on musical issues. It should be added that, as a child, Clara was described as a very taciturn kind of a person; one would guess she was silenced by her domineering father. Owing to her remarkable talents, early recognized by her father, playing the piano for her apparently became a way of life, a haven where she felt safe and competent. Playing may have served as an emotional outlet as well. It is telling that if

she misbehaved, her father punished her by withdrawing lessons. This was a punishment she tried very much to avoid.

After a few years of instruction at home Clara received lessons in composition, harmonics, and counterpoint from the best teachers available. She made her official debut at nine years of age, when she was technically adroit and, more noteworthy, already a talented interpreter. In this respect she clearly differed from other child prodigies of the time, who first and foremost exceeded in, and were admired for, their technical skills. A possible explanation of Clara's interpretative capability at this early age is that playing the piano was a means for her to give voice, not only to the piece of music at hand, but also to her inner life, which she had no other means of expressing. For her, playing and living were closely related. Her ability to concentrate on the piece she played had the rather paradoxical effect that when she first starting performing in front of an audience, she did not suffer from stage fright but was instead terror stricken by the applause after the performance.

Clara Schumann's gift for sensitive interpretation was a hallmark of her 60-year career as a concert pianist. In playing music composed by others, she dedicated herself to conveying not just the composer's music as noted in the score, but the composer's spirit and intent. She specifically abhorred the idea of using other's music to show off as a piano virtuoso (*... I hate the whole world of mechanical virtuoso showpieces*). Robert Schumann and Johannes Brahms particularly testified to her perceptive interpretations of their works. For many years, Brahms – who was known for his unrelenting critique of his own works – used to ask Clara Schumann for her opinion of new pieces he wrote before sending them to his publisher. He continued this practice even after he had become a widely esteemed composer. Reviewers even used to call Clara Schumann 'the priestess,' referring to her refined manners and to her ability to entirely devote herself to her role as interpreter.

Interpretation is one thing, composing another. How did Clara Schumann manage to do both?

As already noted, Friedrich Wieck had required his daughter, from an early age, to write compositions of her own. His goal was to bring forth a first class concert pianist and incipient composer, proof of his superior pedagogical technique. Furthermore, being her father, we may take it for granted that he expected her to mature to become a refined woman by the standards of that day – meaning that he expected her to be both virtuous and unpretentious. Friends of the family attested that as a child and a young teenager, she was conscientious and restrained. However, they also remarked on her wistful smile; it seemed that perhaps she looked at her situation with a degree of irony.

Then, at the age of 16, Clara Wieck fell in love with Robert Schumann, who was then 25. She and Robert had in fact known each other since Clara was 11 years old, when Robert became one of her father's students for a year; as was customary at the time, he lodged in their home. Friedrich Wieck was furious at this development and did everything he could to keep Clara and Robert apart. He sent Clara on extended concert tours where he was her factotum and chaperone as well. However, with some help from friends, the young couple were able to exchange letters from time to time. Robert proposed formally when Clara was 18 but was emphatically turned down by her father. Clara vacillated between opposing

her father and trying to appease him; her father remained adamant in refusing to accept her leaving his household. Finally, Clara and Robert went to the court in Dresden to request permission for Clara to marry without her father's consent. This was granted in 1840, the day before Clara's 21st birthday.

In sum, very little in Clara Schumann's home environment appears to have fostered or encouraged the independent attitude one would have thought necessary for a creative talent to grow and progress (discussed by Smith and Carlsson in 1990).

Interestingly, Clara Schumann's compositions during a short period of time, when she carried through a concert tour on her own and against her father's wishes, differ conspicuously from those compositions that she wrote both before and after the tour. She was 19 at the time and wrote three piano pieces characterized as audacious, spirited, and technically demanding to the extent that it takes a virtuoso to play them – quite against her conviction not to show off on stage. These three pieces invariably brought down the house at her concerts. Opus 8 comprises variations on a theme from Bellini's opera *The Pirate*, opus 9 is an impromptu on Haydn's *Emperor's Hymn* and opus 10, a scherzo of her own invention. Besides confronting her father for the first time, she had recently been awarded the decoration *Königliche und Kaiserliche Kammervirtuosin* (Royal and Imperial Chamber Virtuoso), and been acclaimed *Wundermädchen* (wondergirl) by the emperor Francis II. It does not seem far-fetched to consider this creative outburst an effect of her break with her father leading to a sense of greater autonomy and self-confidence. What about her subsequent development as composer?

Writing music to already existing lyrics constitutes an intriguing two-faceted creative activity. The accompanying music is meant to serve as a congenial illustration and complementary expression of the theme portrayed in the poem and thus contains an element of interpretation. At the same time, it is an independent piece of art, showcasing the composer's temperament and creative powers. Clara Schumann's emphatic and interpretative mastery is evident in the piano settings she wrote to lyrics by Friedrich Rückert, Heinrich Heine, Johann Wolfgang von Goethe, and Robert Burns, most of them between 1840 and 1845. Her settings emphasize and give voice to the essence of the poems. They are harmonically audacious, emotionally outspoken, and musically refined, excellent proof of her capacity to combine creativity and interpretation, as it were. In the preludes the mood of the lyrics are set and the postludes finalize their theme either by letting a prevailing tension burst out in a crescendo or by allowing a tragic atmosphere to attenuate and fade out. Several of her songs were performed by the leading artists of the time.

Since Clara Schumann was not particularly well-read – a result of the very narrowly focused education that her father had given her – it was Robert Schumann, as the lettered party, who selected the 26 poems that Clara Schumann set to music. Most of these poems picture love in various shapes. This is not surprising in view of their recent marriage and the then current fashion of Romanticism. Moreover, composing lieder allowed Clara Schumann to manifest her musical gift in a way that was well in agreement with the roles allotted to women at this time, such as being perceptive and caring *vis-à-vis* the needs of one's

fellow human beings. Further, it allowed her to marry her gifts for creativity and interpretation.

Overall, Clara Schumann's compositions received praise by the public and reviewers alike, among them the most influential critic at the time, Eduard Hanslick and the composer Hector Berlioz. They judged her works as showing competence and craftsmanship as well as power of expression. At the same time, there is a striking difference between her opus 8–10, described above, and the remaining part of her production that, in comparison, contains an element of moderation and self-discipline that sometimes reins in the expression of genuine originality, like a stream in the Alps that remains in its trench even on steep hillsides, as it were. It does not make them less valuable pieces of art – artistry is not equivalent to unexpectedness – but may indicate a restrained creativity.

There is ample evidence that Clara Schumann had a very conflict-ridden understanding of herself as a composer. Both before and after they were married, Robert and Clara inspired each other as composers. Gradually, their life in common as composers became intertwined to the extent that it is possible to trace mutual interdependence in almost everything they wrote. In the 1840s, both wrote pieces for the piano and songs, lieder, a musical form that arose during the romantic era. They studied scores by Bach, Beethoven, and Mozart and played their music together. Robert often encouraged Clara to compose, and he saved everything she wrote. He used his contacts with publishers to have her compositions printed. Yet, she became more and more diffident and reluctant to compose, and her productivity ceased entirely at Robert's death in 1856. Perhaps her creative powers were most genuinely expressed during her teens – when she surprised her father by defying him – and in her congenial yet personal piano settings to lyrics written by the most celebrated poets of her time.

No matter how eager she might have been to compose, Clara's life was filled with other competing and tremendous demands. Particularly after 1840 her duties as wife, mother, and concert pianist took all her strength and time. Between 1841 and 1854, she gave birth to eight children. She spent months on concert tours and also had pupils, to be able to support the growing family. It was a matter of fact, disputed neither by her or her husband, that his time and composing had priority over hers. On top of all this, Robert Schumann suffered from extreme emotional lability, oscillating between periods of exaltation and depression. Over the years his mental state deteriorated and he became suicidal. He had to be hospitalized in 1854 and died two years later.

Thus, it may seem obvious that Clara Schumann's responsibilities as wife and mother were incompatible with a career as composer for purely practical reasons. However, there is evidence that she was literally torn between an urge to compose and succumbing to a lack of self-esteem, sometimes referring to her sex in belittling terms. Before she got married, in 1839, Clara wrote in her diary: *I once believed that I had a creative talent, but I have given up this idea; a woman must not wish to compose – there never was one able to do it. Am I intended to be the one? It would be arrogant to believe that. That was something with which only my father tempted me in former days. But I soon gave up believing this. May Robert always create: that must always make me happy.* On the other hand, composing brought her

deep satisfaction. After having completed the six songs of opus 23 in 1853, she wrote: *There is nothing that surpasses the joy of creative activity, even if only for those hours of self-forgetfulness in which one breathes solely in the realms of tones.* And when she had finished her Trio (in 1846): *There is really no greater pleasure than having composed something and then to hear it.* Yet, later she said about the same piece that it was *women's work, which always lack force and occasionally invention and once described it as effeminate and sentimental.* Her correspondence with Robert about her *Trois Romances* (opus 22) in 1839 is even more revealing with respect to her ambivalence about her creative powers: *I have a peculiar fear of showing you my compositions; I am always ashamed.* She asked him for criticism but objected strenuously when he returned her work with alterations and suggestions, at the same time adding: *You are not angry with me, are you?*

Another factor that may have led to doubts on her ability to compose was that she realized before anyone else that her husband was going to be one of the great composers of his time and that her works, in comparison, might be judged as mediocre or insignificant. He was nine years older than her and well educated which made her feel inferior to him. It goes without saying that male composers also may have doubts on their talents – Johannes Brahms is a telling example – but they were, and still are, urged forward by expectations related to being a man, such as making one's own way. A woman with special gifts, on the other hand, is always reminded of the limits supposedly fallen on her sex.

Clara Schumann, like many other composers who are also performers, maintained that there is an inherent conflict between reproducing and creating music: *For the creative artist it is difficult during any longer time to devote oneself to reproducing. This form of life is rather paralyzing.* This is an interesting comment in view of her profound commitment in interpreting, that is reproducing or recreating, music which – on her level of mastery – requires being able and willing to identify with, relive as it were, another person's intentions.

Composing, like other acts of creativity, on the other hand, implies a rather opposite orientation, that of actualizing and subsequently materializing in one form or another latent, often emotionally laden themes, originating within oneself. Such self-centered activity in creative individuals is coupled with an ability and inclination to assert oneself in relation to other people, that is to defend a space of one's own (discussed in 1986 by Smith and Carlsson). Composing and reproducing music are thus inherently incompatible activities; devoting oneself to one holds back the other. Furthermore engaging in one of them can be expected to result in the other being undernourished and gradually fading out. Clara Schumann had to constantly give concerts in order to support her family. Nevertheless, when Johannes Brahms once suggested that she should give up the strenuous life as a performer, she answered that earning money was not all there was to it. *I feel a calling to reproduce great works, above all, those of Robert, as long as I have the strength to do so. The practice of art is, after all, a great part of my inner self. To me, it is the very air I breathe.*

To sum up, Clara Schumann composed some 60 works, which were positively received by leading critics at the time. At the same time, from the very start of her career, she was known as

a talented interpreter – holding herself back on the stage – which is all the more noteworthy at a time when child prodigies were featured as technical wonders. She rejected superficial brilliance and devoted herself to recreate, that is create anew, the pieces she performed. Robert Schumann and Johannes Brahms have attested to her congenial understanding and performance of their works. Deeply ambivalent about her talents to compose, doubts that coincided with the submissive role allotted to women at the time, she invested her musical ingenuity in presenting compositions written by composers she held in high regard. As for herself: *a woman must not wish to compose – there never was one able to do it.*

Glossary

Intrapersonal intelligence One specific domain of talent, increasingly recognized in creative studies, which in many ways parallels self-actualization.

Self-actualization Openness to and acceptance of one's true self. Leads directly to openness to experience and creativity and epitomizes psychological health.

Theories of Self-Actualization

Self-actualized individuals are thought to be creative. Abraham Maslow, for example, felt that self-actualization and creativity are interdependent. He described how creativity facilitates self-actualization and self-actualization facilitates creativity. In 1971 Maslow even concluded that creativity and self-actualization "may turn out to be the same thing" (p. 57).

Carl Rogers, another leading humanistic psychologist, argued that:

the mainspring of creativity appears to be the same tendency which we discover so clearly as the creative force in psychotherapy – man's tendency to actualize himself, to become his potentialities ... the individual creates primarily because it is satisfying ... because this behavior is felt to be selfactualization. (1961, pp. 351–352)

Empirical Research on Creativity and Self-Actualization

Rogers and Maslow developed their theories of self-actualization by drawing from their experience conducting psychotherapy. Such work gave them extensive information about individuals; however, generalizations from clinical observations are often questioned. This is because (a) generally a small number of persons are observed, and (b) those observed may be atypical in many ways – after all, they are involved in psychotherapy. Fortunately, other more rigorous research has also examined the relationship between self-actualization and creativity.

Some of this research has failed to support the relationship between creativity and self-actualization. For instance, nonsignificant (and low) correlations have been found between four measures of creativity and self-actualization, the former operationalized with the Remote Associates Test (RAT), and the latter with the Personal Orientation Inventory (POI). The RAT may, however, be verbally biased. Moreover, its reliability was in the range between 0.51 and 0.67, which is marginal at best. Convergent validity coefficients were similarly marginal ($0.01 < r_s < 0.48$), which can be indicative of dubious construct validity. The point is that the lack of a relationship between creativity and self-actualization may reflect the measures employed.

Some researchers have operationalized creativity with the Torrance Tests of Creative Thinking (TTCT), which is quite

widely recognized as a reliable estimate of the potential for creative problem solving. Note the emphasis on potential; no test of divergent thinking guarantees actual creative performance. Divergent thinking tests are predictors rather than criteria of creativity. Note also the emphasis on problem solving. Some creativity may be more self-expression than problem solving – and this may be especially true of the creativity that is related to self-actualization. Creativity was also operationalized with the Similes Preference test.

Murphy and colleagues found that POI scores were significantly and positively correlated with the elaboration index from the TTCT. They did not provide the actual correlation coefficient, so it is impossible to really interpret the relationship. POI scores were unrelated to the originality fluency TTCT scores, and were unrelated to performances on the Similes test.

Mark Runco and colleagues suggested that the relationship between creativity and self-actualization could only be accurately assessed if creativity was operationalized in terms of personality and process. These reflect two common perspectives on creativity. The personality approach posits that there are core characteristics or traits that are functionally associated with creative behavior. The process orientation posits that creativity may not result in tangible products but should be understood as a perspective on life.

Maslow was explicit about the distinction between personality and product. In his words, SA creativeness stresses first the personality rather than its achievements, considering these achievements to be epiphenomena emitted by the personality and therefore secondary to it. It stresses characterological qualities like boldness, courage, freedom, spontaneity, perspicuity, integrity, self-acceptance, all of which make possible the kind of generalized SA creativeness, which expresses itself in the creative life, or the creative attitude, or the creative person. I have also stressed the expressive or Being quality of SA creativeness rather than its problem-solving or product making quality (1968, p. 145).

Maslow gave these traits when defining self-actualization: acceptance of self, others, and nature; detachment; a desire for privacy; autonomy; resistance to enculturation; problem-centering; and democratic character structure. Most of these are also characteristic of the creative personality.

In their research, Runco and colleagues used two well-respected measures of the creative personality: the How Do You Think Test (HDYT) and the Adjective Check List, which has a Creative Personality scale. They also administered the

Self-Actualization Scale (SAS). Four scores were derived from the HDYT responses, and each was significantly and positively correlated with the SAS scores. It thus appears that the relationship between creativity and self-actualization does indeed depend on the measures employed. Importantly, although the findings of Runco and colleagues were contrary to the other two empirical studies on this topic, the findings were consistent with the observations of Rogers and Maslow. This suggests that the findings are trustworthy because they were predicted first by theory and then confirmed with empirical tests.

Lynne Buckmaster and Gary Davis also reported a positive and significant correlation ($r=0.73$) between creativity and a measure of creative personality traits. In particular, Buckmaster and Davis uncovered a creativity factor that accounted for a significant portion of variance in an eight-factor factor analysis. This analysis included the Reflections of Self and Environment (ROSE) measure, which is a self-report focusing on self-actualization. There are two questions with this factor analysis: First, the creativity factor accounted for only 18.9% of the variance in the scores, perhaps because it was a fairly select sample of subjects. The subjects were all students in a creativity course. This may have restricted the range of scores. It was also a relatively young sample of subjects, which is an issue because self-actualization might require some experience and maturity. There is a debate in the psychological literature about the possibility of self-actualization in young persons. The second question concerned the ROSE index, which was more correlated with the creativity scores than it was with the POI scores ($r=0.26$).

The low correlation with the POI raises the issue of construct validity. Still, by and large these results were consistent with those of Runco and colleagues. Thus in the two studies that relied on personality measures a positive and significant correlation was found between creativity and self-actualization.

Runco and colleagues used the Adjective Check List. This is a self-report containing 300 adjectives. Respondents indicate which are self-descriptive. The vast majority of persons whose SAS scores were in the top 25% of the sample used these adjectives to describe themselves: Adventurous, Alert, Appreciative, Clever, Dependable, Friendly, Helpful, Honest, Loyal, Active, Adaptable, Capable, Easy-Going, Formal, Humorous, Intelligent, Interests Wide, Kind, and Mature. None of them described themselves as Commonplace, Conceited, Cruel, Despondent, Distrustful, Dull, Gloomy, Queer, Slipshod, Stolid, Sulky, Unintelligent, Unkind, or Unstable.

Creativity and Health

Both creativity and self-actualization are indicative of psychological health. As is the case with most signs of health, however, it is not easy to determine which comes first. It is possible that self-actualization allows the individual to be creative, or that the creative tendency supports self-actualization. It is also

possible that both are results of a third variable. This third variable might be the capacity for effective coping, adaptability, or intrapersonal intelligence. Recall here that Rogers said, in the quotation earlier, that self-actualization and creativity both reflect an underlying motivational force.

It does appear that some creative persons are not self-actualized. Some are certainly not healthy. In fact, creativity can be downright destructive. The dark side may be seen in creative but destructive discoveries and inventions, such as thermonuclear weapons, and in the not uncommon self-destructive behaviors of creative persons. This self-destruction may take the form of suicide or alcoholism.

Conclusions

There is evidence that creativity and self-actualization are related. This relationship follows from the theories of Carl Rogers and Abraham Maslow, and was apparent in both clinical observations and some correlational studies. As is the case with all correlations studies, however, there is some uncertainty about the direction of effect. Creativity may lead to self-actualization, or self-actualization may support creativity. They may both reflect a third variable, such as coping or adaptability. And neither guarantees the other. There are many cases of unhealthy creative persons. This is not much of a surprise, if we keep in mind that there are different ways to be creative. Some individuals are creative in their work, and some in their leisure. Some are creative when they solve problems; others are creative only when they are not threatened by problems.

Although some creative persons may be self-actualized, and that self-actualization may in fact be necessary for their creativity, other individuals may be creative without self-actualizing. Both creativity and self-actualization are multifaceted constructs, and this gives them any number of possible intersections.

Serendipity

R Horan, School of Design, The Hong Kong Polytechnic University, Hong Kong

© 2011 Elsevier Inc. All rights reserved.

Glossary

Abductive reasoning The process of logical inference which intuitively connects seemingly unrelated facts, often leading to a hypothesis.

Creative contemplation The intentional, yet dispassionate, delivery of a conscious problem to the deep unconscious mind for creative processing (in Sanskrit, *sanyama*).

Determinism Theory that acts of will, natural occurrences, and psychological phenomena are causally determined by preceding events or natural laws.

Dual serendipity Serendipity and pseudoserendipity participate in the same discovery process.

Indeterminism Theory that certain acts of will, natural occurrences, psychological phenomena have no cause and therefore exhibit freedom and spontaneity.

Pseudoserendipity Discovery by accidental means of things sought for.

Quantum leap The discontinuous, very fast 'jump' of an electron from one energy level to another after a brief existence in a state of superposition.

Quantum uncertainty The boundaries of reality are determined by the limit of man's ability to observe, and measure, the universe at the quantum level.

Serendipity *Walpole* discovery by accidental means, and sagacity, of things not sought for.

Synchronicity *Jung* the simultaneous occurrence of two, or more, meaningful events that are not causally connected.

Origins

The term *serendipity* was coined by British writer and politician, Sir Horace Walpole, in a letter to his friend, Horace Mann, on January 28, 1754. Walpole shared, therein, his good fortune in discovering an old book with the Capello coat of arms, an emblem he sought to adorn the frame of a cherished painting, sent to him by Mann, of Bianca Capello, the Grand Duchess of Tuscany. Walpole refers to her as 'her serene highness.' Walpole attributes his luck to an uncanny ability of finding "everything I want *à point nommé* when I dip for it" (Horace Walpole, Wilmarth S. Lewis (ed.), 1960: 408). The phrase *à point nommé* means 'to be in the right place at the right time' and *dip* denotes his intention. Arthur Koestler called this type of discovery the *library angel*, a class of fortunate coincidences involving libraries, references, quotations, etc. Combs and Holland, in *Synchronicity: Science, Myth and the Trickster*, regarded such anomalies as examples of *synchronicity*, or meaningful coincidence, a term first used by Carl Jung in 1935. Walpole, however, likened his discovery to a new construct:

This discovery indeed is almost of that kind which I call *serendipity*, a very expressive word, which as I have nothing better to tell you, I shall endeavor to explain to you: you will understand it better by the derivation than by the definition. I once read a silly fairy tale, called *The Three Princes of Serendip*: as their highnesses travel, they were always making discoveries, by accidents and sagacity, of things they were not in quest of . . . (Walpole and Lewis, 1960: 408).

A careful reading of *The Three Princes of Serendip* illuminates the nature of serendipity and its relation to creativity. *Serendip* is an ancient Persian corruption (*sarandib*, *serendip*) of the Sanskrit *Sinhaladvipa*, a name for Sri Lanka (previously Ceylon). The tale cited by Walpole forms part of a collection by Christoforo Armeno published in Venice in 1557. In the tale, three loyal, academically adept princes are banished by their

father, King Giaffer, as a ruse to increase their worldly experience. While traveling, they are thrown to the vagaries of fate, encountering many unexpected challenges. They confront each challenge openly (apparently nonplussed with potential failure) and prove their worth through astute observation and sagacity. For example, one prince determined that a missing camel was blind in its right eye because grass was eaten only on the left side of the road where grass was less thick. Empathetic to a young queen's plight, another prince foiled a huge open hand which regularly emerged from the sea to drown her unwary subjects. The prince effectively countered its power with two outstretched fingers, a symbol of victory. His rationale was this: while the hand represented the power of five men to conquer the world, his two fingers demonstrated that two men are enough. The types of problems faced by the princes are similar to the insight problems utilized in creativity research. The princes' innate abilities matched the challenges they faced. Their desire to serve humanity, lack of self-consciousness and concern for failure, and an open undistracted focus on the moment invites a connection to Csikszentmihalyi's concept of flow, developed in 1996 to describe the psychology of discovery and invention. Serendipity, as depicted in the tale, integrates meaningful chance occurrences with creative intelligence, wisdom and an objective, almost serene, attitude toward constraints.

The Oxford English Dictionary, first to list the word, defines serendipity as "the faculty of making happy and unexpected discoveries by accident" (*The Oxford English Dictionary*, 2nd edn., 1989: 5). Serendipity has played an important role in many fundamental scientific discoveries such as Newton's universal law of gravitation, Archimedes principle, electromagnetism, dynamite, the Dead Sea scrolls, Teflon, cellophane, rayon, penicillin, X-rays, Velcro, bioelectricity, radioactivity, the microwave oven, and so forth. It is often characterized by unintentionality, accident and sagacity. Royston M. Roberts in

his book, *Serendipity: Accidental Discoveries in Science*, coined the term *pseudoserendipity* to differentiate true serendipity from accidental discoveries involving intention. In 1995, Diaz de Chumaceiro and Yaber suggested *dual serendipity* to describe the combined presence and absence of intention in a serendipitous event. As Walpole noted, there also appears to be an overlap with the construct of synchronicity which can also be intentional, or not. Since Walpole's conception, few empirical studies have been conducted on serendipity's creative origins largely because of its acausal nature, small sample sizes, the challenge of measuring intention and the need for an accurate taxonomy within the spectrum of meaningful coincidences. Most discussions on serendipity include examples, anecdotes and testimonials provided by serendipitous discoverers and/or their biographers. Consequently, many publications have applied case studies in an attempt to classify serendipity as discovery by accidental means with, or without, intention. The importance of sagacity has also been mentioned. This article has taken an alternate, more in-depth, approach to the phenomenon by presenting scientific theory and evidence stemming from closely related areas of study. It is hoped that some readers will be inspired to delve more profoundly into the phenomenon of serendipity which could eventually lead to new ways to empirically investigate it. To facilitate this, serendipity's overlap with synchronicity, its acausal, sagacious, and intentional attributes must be addressed.

Serendipity and Synchronicity

Meaningful coincidence is a broad description of unforeseen external events that elicit some benefit (or change) to the observer. Jung used the term *synchronicity* to describe this class of phenomena. Synchronicity has been associated with serendipitous occurrences such as Newton's apple and Archimedes's bathwater as well as a host of parapsychological phenomena including telepathy, precognition, retrocognition, remote viewing/healing, psychokinesis, and poltergeists. According to Jung's model, the external event and the inner state of the observer are not connected causally but by a mutual resonance of meaning called the *archetype*, a construct containing symbol or myth. Ira Progoff, in *Jung, Synchronicity, and Human Destiny*, suggested that emergents (a term Henri Bergson used to describe novel elements manifested in the process of evolution) include synchronistic coincidences emerging acausally from an individual's core creativity. Synchronistic events appear accidental or intrusive due to their acausal nature. Synchronicity, like serendipity, may be devoid of any apparent intentional element. Examples are parapraxes (e.g., slips of the tongue inviting reflection) and repetitive patterns (i.e., common themes, ideas, or events that tend to reoccur). In certain contexts, synchronicity complements an intention. Examples are library angels, remote viewing/healing, induced telepathy and telekinesis. Alan Vaughn in *Incredible Coincidence* notes that an interest in synchronicity increases synchronistic occurrences.

Synchronicity may be divided into two types (Types 1 and 2) based on the absence or presence of conscious intention, respectively. Synchronicity is therefore defined as two or more observations (i.e., measurements) of temporally synchronous, spatially separate, and apparently causally unrelated phenomena (an element(s) or state of the mind (P, e.g., archetype) and some

external event(s) (E)) that become entangled reflectively within a similar space of meaning (P(E)) and are either consciously sought for (Type 2), or not (Type 1). Entangled systems are spatially separate yet integrated within a single state without a specific time definition; that is, they are simultaneously linked. Synchronicity, though capable of challenging an observer's 'either/or' thinking, does not ensure originality or creative output.

Serendipity is historically construed to be devoid of conscious intention. The term has been modified by some researchers to interpret accidental discoveries associated with consciously directed problem finding and solving. Meaning found in serendipitous events, unlike synchronicity, is less immediate. It requires a special skill Walpole called *sagacity*. To better classify serendipity and clarify its overlap with synchronicity, an adaptation of the 1991 serendipity equations developed by Dias de Figueiredo and Campos is applied so that metaphor (herein called an operator) provides the mechanism for serendipitous discovery. An operator does not necessarily entail the deep resonance of Jung's archetypes. Serendipity is also characterized by the presence (Type 2), or absence (Type 1), of conscious intention. It is therefore defined as two or more observations (i.e., measurements) of temporally synchronous, spatially separate, and apparently causally unrelated phenomena (an element(s) or state of the mind (P₁, e.g., an initial problem) and some external event(s) (E)) whereby an operator (x) entangles with the external event (E(x)) providing a new space of meaning (P₂, e.g., new problem and/or solution) that is associated with P₁ and *consciously* sought for (Type 2), or *is not* associated with P₁ and *not consciously* sought for (Type 1).

Both serendipity and synchronicity involve observation; an apparently acausal, yet synchronous, relationship between inner and outer events in which informational boundaries are bridged; salience; and the presence, or absence, of intentionality depending on which type is evidenced. Serendipity, however, displays distinct differences: (a) the external event is acted upon by an operator which creatively alters or shifts, not merely influences or activates, the original problem space; (b) insight generates originality in finding a new problem, restating the initial problem and/or solving the initial problem in a new way. The term operator signifies that some instances of serendipity (more generally Type 2) are not metaphorical. They arise from false notions or additional observations about the initial problem (e.g., Christopher Columbus' belief he'd found a direct route to the Indies instead of the New World and Jacques Brandenberger's discovery of cellophane for food packaging after rethinking his viscose-coated, airtight, water-proof tablecloths, respectively). In 1994, Pek van Anandel listed what he called 17 basic serendipity patterns including analogy, observation, error, information alteration, inversion, false (or lacking) hypotheses, belief testing, interruption and disturbance, playfulness, jokes, and dreams of forgetfulness. Operators act through the dynamical nature of these patterns.

Alexander Fleming's discovery of penicillin in 1928 is often cited as Type 1 serendipity. Fleming was investigating antibacterial agents (P₁). He had cultures of *staphylococci* bacteria in his lab when, 1 day, he noticed a discarded culture had been contaminated with a rare *penicillium* mold from the hospital's mycology lab downstairs. The culture had unexpectedly developed an unusual growth pattern, eliminating the bacteria

(E(x)). Fleming was known to habitually pursue odd phenomena. He quickly realized penicillium's potential as an antiseptic agent (P₂). Through his initial efforts, and the persistence of others, the drug penicillin was proven an effective therapeutic agent in the field of antibiotics. Note that P₂, the new solution, is closely associated with both P₁ and Fleming's original intention to discover effective antibacterial agents. Fleming's discovery is actually an example of Type 2 serendipity.

On the other hand, Wilhelm Röntgen's discovery of X-rays, in 1895, exemplified Type 1 serendipity. While attempting to detect cathode rays from an evacuated glass tube fitted with a black cardboard sheath (P₁), he noticed that a distant cardboard screen coated with *barium platinocyanide* fluoresced with each discharge of the tube, regardless of which side of the screen the tube faced. The anomalous energy penetrated the black cardboard sheath and operated at distances beyond the effective range of cathode rays in air (E(x)). He realized that he was witnessing a new phenomenon. He later used it to record a skeletal image of his wife's hand on a photographic plate (P₂) confirming the existence of X-rays. Röntgen's discovery exemplifies Type 1 serendipity. He never intended to discover a new form of electromagnetic radiation and the problem (skeletal imaging) was original.

Meaningful coincidences fundamentally represent a creative self-world dynamic. Synchronicity reconnects the self with the world via a mutual resonance that redefines, or enlarges, the sense of self. This resonance is meaningful (though not necessarily pleasant) and therefore not perceived as being in error. In 2002, Rita Durant suggested that synchronicity can act as a destabilizing mechanism which blurs, or even threatens, the essential distinction between self and world. Such psychological border conditions could result in creative insight. Serendipity, alternatively, defies an observer's knowledge by disconnecting an existing articulation of self and world by the appearance of an anomaly or error, and then challenges the self to reconnect to the world in a new meaningful way. The disarticulated event in conjunction with an operator, and insight, becomes the foundation for new associations. Albert Rothenburg, in 1988, preferred the terms *articulation of error* and *conversion of error* in describing these discrepancies in order to differentiate serendipitous events from other meaningful coincidences. He attempted to put serendipity on a more solid scientific foundation by replacing chance with the less ambiguous word, 'error.' Chance, however, is considered by many researchers as an important element of creativity.

Chance and Creativity

In 1981, Francis Crick, codiscoverer of the DNA structure, said "chance is the only source of true novelty" (Francis Crick, 1981: 58). Chance is derived from the old French *cheance* which described the accidental falling of dice. In modern usage, chance denotes the absence of cause in events that are predicted, understood, or controlled; or the probability of an event occurring. There are two fundamental approaches to understanding acausal events: (1) the event is deterministic but individuals lack the 'all-seeing' purview required to delineate the complex causal patterns involved; and (2) the event is purely indeterministic, or stochastic by nature.

The Deterministic View

Classical (traditional) physics is deterministic. It includes Newton's laws of motion, classical electrodynamics, thermodynamics, the special theory of relativity, the general theory of relativity, chaos theory, and nonlinear dynamics, etc. Some of the systems described by these laws are highly complex (e.g., weather patterns) and difficult to predict in practice. However, if initial conditions are known in sufficient detail, the random output of such systems becomes predictable. In 1996, Tobi Zausner described creativity as a chaotic or nonlinear dynamical system (NDS). She proposed that creativity, like chaotic processes:

- systematically dissipates information and energy;
- fosters open exchange between an individual and the environment, knowledge domain, social and political structure, culture, etc.;
- iterates in the development of ideas;
- is time irreversible;
- adapts and self-organizes into creative expressions or products;
- is autocatalytic via positive feedback loops involving reward;
- allows bifurcation of ideas and processes, and;
- exhibits far-from equilibrium conditions especially during periods of inspiration.

Perhaps, the most important component of NDS is sensitivity to initial conditions, often referred to as the 'butterfly effect.' This effect manifests as an exponential growth of error causing a system to behave as though it were random. Tiny differences in the systems' initial state result in enormous changes in its final state (even over small timescales) giving the impression of random behavior. The butterfly effect involves a unique confluence of space-time events. The butterfly, in fact, doesn't initiate a storm on the other side of the planet. It's simply 'in the right place at the right time.' Its wing motion is integral to an underlying pattern which actualizes the complex escalation in weather patterns. Walpole's *à point nommé* becomes no simple matter. Chance discovery, from a chaos perspective, is deterministically subject to initial conditions, yet unpredictable. Creativity exhibits unpredictability most remarkably in the timing of insights and in the nature of their content. Serendipitous discovery is externally unpredictable in the emergence of random events that elicit insight.

In 1984, Prigogine and Stengers noted that far from reaching equilibrium, nonlinear systems become exquisitely sensitive to variable changes. This phenomenon also appears in creative individuals. In 1996, Martindale and others observed that creative individuals are significantly more sensitive to physiological stimuli, habituate more slowly, and remain alert to incoming stimuli even after developing a cortical model for them. Similarly, scientists who make serendipitous discoveries are sensitive to random variations in their environment and are capable of suspending focus on an initial problem to explore alternate routes of investigation. They exhibit opportunism in the recruitment of chance permutations. Chance-related opportunity is minimized in areas bearing well-established principles from which specific results can be deduced. It is maximized where the frontier of knowledge is wide open and phenomenological causes are hidden. In 2003, James Austin suggested that

serendipitous chance is enhanced by acute observation and sagacity as well as variability due to increased physical mobility (e.g., the traveling princes) and unique, or individualized, motor behavior corresponding precisely to the external environment in ways that allow for unusual approaches and favorable circumstances in discovery.

In 2004 Simonton, using Darwin's biological evolution model, proposed that the acausal nature of serendipity arises from an 'as if' blind combinatorial process. This quasi-stochastic element results from the unpredictability of spontaneous combinations in a rich environment of cross-connections among a diversity of simultaneous projects and professional/recreational behaviors which, in themselves, represent serendipitous effects. Serendipity is spontaneous but not accidental. It depends on the quantity of combinations within a given time period, combinations that are at some level causally linked. Simonton further hypothesizes that creative chaos in the conscious mind pales in comparison to the multiplicity of unconscious creative thought processes which are highly fertile ground for serendipitous effects. When openness to 'irrelevant' phenomena produces manifold associations leading to one original solution, that solution's probability of occurrence is exceedingly low with respect to the total number of unconscious and transient thoughts that induced it. This implies that serendipitous effects in the conscious mind are significantly lower than those in the unconscious mind. In the deterministic perspective, chance is due to 'hidden variables' and a fundamental ignorance of causality. Unconscious processes are important hidden factors. This model, however, relegates choice (and therefore creative decisions) to those same natural processes.

Similar to the evolutionary model, computer scientists for over 20 years have explored implementing a background of subtle agents for randomly searching, browsing, playing with, and filtering interesting information in order to duplicate serendipity-like chance. In 2009, André Schraefel and others noted that in one study, 21% of all potentially serendipitous web search results were found interesting but irrelevant to the user's original query. They proposed using background recommender systems to provide interesting, personalized information which is unknown and unexpected. However, support for human insight, and sagacity, is a greater challenge. To elicit insight, they suggest that computers track user's existing domain knowledge and offer opportunities for extending it by highlighting knowledge gaps and offering collaborative cross-fertilization with other domains under a common language. This does not mean that the user will recognize a meaningful coincidence and make a discovery. The mechanisms proposed by this computational approach are also deterministic. Perhaps the foremost hidden variable lies in the design of the system itself.

The Indeterministic View

Quantum mechanics, a form of indeterminism, has demonstrated classical physics to be fundamentally flawed. Heisenberg's uncertainty principle provides evidence for the pure stochastic nature of both micro- and macroscopic phenomena. In quantum physics, initial conditions cannot be known with certainty because the initial conditions of any system (NDS for example) stem from immeasurably minute fluctuations in a

long causal chain which is traceable to the earliest phases of the universe, where quantum uncertainty reigned. Quantum physicists declare that radioactive decay and the movement of elementary particles are also completely random. Since macroscopic phenomena are composed of elementary particles, randomness is an intrinsic aspect of all observed reality. In 2000, Evan Harris Walker compared macroscopic reality's dependence on the uncertainty principle to a game of dice. If a die's velocity, direction, angular momentum, point of impact and orientation angle on impact is exactly known, classical physics can exactly determine its motion. However, the uncertainty principle puts a limit on the precision of calculating complementary physical components. Both the velocity of the die and its position cannot be known exactly; neither can its angular velocity and orientation on impact. Its future motion can only be represented by a smeared-out state of probabilities falling within these uncertainties. Furthermore, uncertainty escalates with each bounce of the die. The die formally exists as a linear superposition of states (all orientations at once). Observation is what keeps the die in one position over another. In short, quantum randomness, or pure chance, is affected by an observer's choice. Schrödinger's cat, a famous thought experiment in which a cat's survival within a closed box is indeterminate prior to opening the box, is another example of this principle.

Einstein was frustrated by quantum uncertainty. He once declared that 'God does not play dice.' In 2006, quantum teleportation investigator, Anton Zeilinger disagreed. While commenting on nature's freedom, he said, "It is so random that not even God knows the answer" (Anton Zeilinger, Interview, 16 February 2006: 8). These diametrically opposed positions are not yet resolved. Quantum mechanics, however, using probabilistic formulations, is the most precise measurement system known to man. It allowed for innovations like the laser, transistors (e.g., basic components of CPUs), and magnetic resonance imaging. It also underlies quantum computer development. In 2006, Rosenblum and Kuttner said that the enigma of quantum physics rests in juxtaposing its empirical accuracy with the measurer's consciousness affecting measurement, a 'minor point' most working physicists choose to ignore. Quantum physics challenges our concepts of time, chance and the separation of self and world. Its view of nature appears to resonate with unusual phenomena like synchronicity and serendipity (especially Type 2).

Amit Goswami, in his book *Quantum Creativity*, connects what Michael Polanyi, in 1998, referred to as the 'logical gap' arising at the actual moment of creative illumination and the discontinuity of nature at the quantum level described by the quantum leap. Quantum leaps occur in atoms when electrons jump instantaneously from one energy level to another much like the discontinuous leaps found in creative insights. Between quantum leaps, electrons exist as infinitude of probabilities similar to the ambiguity that permits divergent thinking. Ambiguity in creativity may actually stem from subconscious awareness of indeterministic, noisy neuronal processes.

Another chance-related quantum phenomenon is nonlocality, or entanglement. Entanglement occurs when the common state of particles, after interaction, is not the product of their individual states, regardless of the distance between them. Alterations to the property of one particle influence,

instantaneously, its entangled partner. Because there is no apparent cause, quantum events appear random. This implies at the macro level that humans, as products of the Big Bang, are basically, variously, and instantaneously interconnected with the entire universe. Their actions don't have random consequences. Theorists like Roger Penrose, Henry Stapp, and Evan Harris Walker propose that the micro universe of the brain acts in the neuronal synapse like a quantum computer, giving it more computational power than previously imagined. Goswami, blending both universes posits that creativity is enhanced through greater awareness of the interconnectivity between self and world.

Unlike the deterministic approach where chance is fundamentally nonexistent, quantum physics suggests that all information past, present, and future exists in a superpositioned, or coherent, state and that the emergence of a new association is dependent upon some form of 'observation' on the part of nature. Barring Hugh Everett's 'many-worlds' interpretation where all space-time trajectories exist with equal certainty in multiple dimensions (e.g., simultaneous different solutions for one life), the basic uncertainty in nature allows for free choice, placing creativity at the very core of consciousness. Furthermore, quantum entanglement does not discount the possibility that conscious, perhaps unconscious, choices influence 'objective' reality to synchronize meaningfully with the individual. The range of influence, however, is limited by the general theory of relativity to the speed of light thereby 'localizing' empirical observation. It takes about 77 ms for information traveling at light speed to circuit half the globe, less than the time it takes to process a thought. In the quantum view, 'chance,' as an acausal property of the observer's capacity for choice, supports creative insight through the entanglement of many nonlocal, nonapparent associations. Chance, in the indeterministic perspective, suggests that phenomena like synchronicity and serendipity are emergent properties of the consciousness relationship between the creative individual and the world, whereby one profoundly reflects the other.

Sagacity and the Prepared Mind

During a lecture delivered in 1854, Louis Pasteur said, "In the fields of observation, chance favors only the prepared mind" (Louis Pasteur, Lecture University of Lille, 7 December 1854). The history of scientific discovery is full of examples of what were missed serendipitous opportunities by the final discoverer's predecessors including the discovery of fission, the role of vitamin C in scurvy, DNA, penicillin, and X-rays. Besides extensive domain knowledge, language ability and capacity for logical, critical, and convergent thinking comprised of analysis, synthesis, planning, deduction, induction, memorization, etc., the scientifically creative mind exhibits some special attributes.

Since J. P. Guilford's 1950 address to the American Psychological Association in support of creativity research, researchers have discovered many characteristics of the creative mind that may enhance serendipitous effects including divergent thinking as mental fluency (generate many ideas), flexibility (generate multiple categories of ideas), and originality;

orientation toward novelty; imagination; flat associative hierarchies; capacity for remote associations; openness to experience; cognitive playfulness; curiosity and questioning; ranging interests; tolerance for ambiguity; sensitivity to external stimuli and nuance (more prevalent in artists); empathy; intuition and insightful thinking.

In 2007, Horan proposed that the preparation and verification phases of Graham Wallas' creative process depend on intelligence and the discrimination to recognize, evaluate, and manipulate information, ideas, and constraints while incubation and illumination phases depend on dispassion, motivation, and the capacity to transcend those constraints. Creativity's basic predisposition is to challenge/extend boundaries and overcome limitations, or what David Perkins, in 1988, called 'boundary fiddling.' This attribute takes effort, perseverance, and the willingness to take risks. In 1992, Rubenson and Runco postulated that experienced researchers who are unwilling to entertain new perspectives but expend energy on defending previous achievements may be adverse to the psychic risk of having their previous achievements devalued or invalidated. Assuming this is correct, the capacity for serendipitous discovery, among this group, would be minimized even though serendipitous events do occur.

From a reasoning perspective, serendipitous discovery differs from knowledge discovery because knowledge discovery extracts certain patterns from data while serendipitous discovery predicts future outcomes from a multitude of possible outcomes. Not everyone is adept at prediction. The science of economics provides many good examples. By 1976, executives from most major Hollywood film studios had rejected *Star Wars* saying that science fiction films were unmarketable; in 1943, Thomas Watson, the chairman of IBM predicted a world market of only five computers while in 1970, Ken Olsen, founder of Digital Equipment Corporation reportedly said there is no market for personalized home computers. Alan Ladd (CEO of 20th Century Fox) and Bill Gates (CEO of Microsoft) looked at alternate possibilities, successfully.

Serendipitous discovery challenges both inductive and deductive reasoning because both are limited to present and/or past information. While inductive reasoning determines a value, deductive reasoning formulates the consequences of a hypothesis. Neither guarantees accurate predictions in an ambiguous environment. In 1965, Charles Sanders Pierce, proposed that creativity arises from abductive reasoning defined as a logical process used in the formation of explanatory hypotheses and the introduction of new ideas. Serendipitous discovery is abductive. It requires creative, insightful thinking. In *The Three Princes of Serendip*, some of the princes' insights were likely inductive (e.g., blind camel) while others (e.g., the open hand) were abductive by virtue of their multipotential outcomes.

Creativity researchers use insight problems like the nine-dot problem to assess creativity. There is doubt over the efficacy of this approach because solutions already exist though they are peripheral to results generated by common problem-solving approaches. Real-world creativity, and therefore serendipity, does not have this luxury. Walpole described the three princes as being sagacious. In 2003, Robert Sternberg observed that sagacity, or wisdom, though correlated with creativity, has a closer affinity with intelligence. Citing King Solomon's clever determination of a child's real mother, he suggested that wise

solutions to problems often require creativity when they lack obviousness. While routine problems utilize common sense, wisdom problems embody novelty by presenting new features not evident in old problems.

Sagacity, not routine problem solving, decides serendipitous discovery. In hindsight, sagacious solutions may appear as the only possible solutions derivable from the data. Progress in science has shown repeatedly that this is not a truism. Until the early 1900s, Newton's clockwork universe was the prevalent paradigm in physics, though Newton doubted its completeness. Einstein shifted Newton's paradigm with his general theory of relativity. Soon after, the foundations of classical physics were disputed by quantum mechanics.

Whereas synchronicity appears to be ubiquitous, reports of serendipitous discovery are notably absent in the fine arts, except for rare examples like Picasso's serendipitous decision to enter a blue period. This observation helps to highlight an important aspect of the scientifically prepared mind and its relation to sagacious insight; that is, the requirement of objectivity. Kantorovich (1993) suggested that whereas scientists and inventors are constrained by observational data which must conform to the natural world, experimental results and the zeitgeist (spirit of the times); art is constrained solely by the zeitgeist.

Scientists' creative problem solving is channeled into solutions that exhibit consensual validity, or objective efficacy, within a specific domain. To achieve this, problems must be falsifiable and solutions tested and retested until their objective merit is suitably proven. Serendipitous discovery in science, similarly, is distinguished by the objectivity that scientists labor under. Objectivity, implied in Walpole's concept of serendipity, is a combination of *serene* detachment and the ability to investigate (or *dip* into) phenomena. In the art domain, serendipitous discovery is accepted as part of the artist's natural exploration of a particular creative space in the development of new forms of subjective expression. In this regard, it is not surprising that the most highly reported serendipitous discoveries are those in which solutions significantly impact humanity's more utilitarian needs.

Creative Intention

In 1999, Conti and Amabile proposed that creativity is motivated by psychic conflict or self-actualization. Psychic conflict is prevalent in individuals suffering from mental disturbances such as bipolar disorder or affective illness. Creative expression is effective in channeling anxiety induced by psychic conflict in some individuals. Self-actualization, alternatively, is evident in individuals pursuing important problems, often of a humanistic nature. In both cases, the primary drive is to overcome limitations. Whereas psychic conflict diminishes a premature, perhaps conventional, sense of psychological closure (and satisfaction) thereby fostering new avenues of thought, self-actualization sensitizes individuals to existing boundary conditions inspiring attainment of individuals' full potential.

In 2007, Horan addressed both factors by describing creativity as the "manifestation of the intention to transcend the limitations of information" (Roy Horan, 2007: 182). It would seem that simply having an intention (motivation) to solve

a problem creatively does not preclude creative output. Intention must be supported by a prepared mind, genetics, personality, education, family, zeitgeist, etc. The proclivity, however, to display creative intention involves some, if not all, of all these factors. Combs and Holland noted increased reports of synchronicity induced by psychic conflict (boundary conditions) and self-actualizing practices like meditation. The relationship between intention, synchronicity, serendipity, and other meaningful coincidences has not been adequately investigated.

Serendipity is divided into two types according to the existence, or absence, of conscious intention. What is less obvious in this taxonomy is that intentions can be conscious and/or unconscious. Sometimes these intention levels may conflict. For example, parapraes occur when unconscious intent surfaces unexpectedly during situations where conscious intent is otherwise oriented.

Poincaré, Pauling, and others have attested to unconscious processing during creative incubation. In 1985, Oakley and Eames cited neuropsychological studies of unconscious information processing being reflected in behavior. In 1998, Baars indicated that the unconscious mind's capacity for processing information exceeds the conscious mind. Volition is an important element in both conscious and unconscious processes. In 1925, William James described volition as "nothing but attention" (William James, 1983: 424). Posner (1994) stated that attention appears at all levels of information processing including consciously directed, sustained attention. In 2001, John Taylor indicated that subconscious goal-directed attention is woven into perspectivalness, the sense of having a point of view. Therefore attention (intention) is, at all levels, a form of choice.

In 1987, Yaniv and Meyer proposed that unsuccessful attempts at problem solving activates memory traces relevant to a solution, but when attention is engaged elsewhere the activation process sensitizes the individual to chance encounters with external stimuli that are further integrated into trace information. This mechanism reflects the common experience of 'keeping a problem on the backburner' (incubation) while unconsciously seeking appropriate solution stimuli. If incubation is sustained, the chance of relevant stimuli appearing increases. This may also account for how apparently random external stimuli found in serendipitous events react with unconscious attentional processes to induce insight. For example, if sustained, perhaps lifelong, unconscious intentions like discovering the nature of reality, its underlying physical principles, or developing innovative products exists simultaneously with specific intentions like testing a radio-telescope antennae (e.g., cosmic background radiation leads to the Big Bang theory), deducing why the moon remains in orbit (e.g., falling apple leads to the universal theory of gravitation), or testing a magnetron for radar sets (e.g., melted candy bar leads to invention of the microwave oven), those unconscious intentions could conceivably direct an individual's awareness, and curiosity, toward the investigation of unusual phenomena.

The more poignant question, perhaps, is: Can unconscious intentions influence the seemingly random events involved in serendipitous discovery? In *The Intention Experiment*, Lynne McTaggart reviewed a considerable amount of serious research

on parapsychological phenomena. She noted that intention can have a nonlocal/nonrandom influence on biological systems and random event generators (REGs – electronic devices driven by quantum fluctuations). The effect sizes, over many studies and trials, were significant though generally quite small. Effects also tended to decline over time.

In 2007, von Lucadou and others provided empirical evidence that: (a) the decline in effect size is balanced by an acausal displacement toward noncomparable variables; that is, other apparently unintended phenomena are affected by the original intention; (b) the process does not involve any known form of signal transfer; and (c) individuals with innovative behavior, though less motivated than other subjects to participate in a REG experiment, demonstrated an increase in nonrandom effects. Results imply that creatives may naturally induce meaningful coincidences.

Empirical confirmation of this phenomenon may be feasible via nontraditional experimental designs. Though the exact mechanisms of these intentional influences are presently unknown, and often contested, unconscious processing is suspected. The larger effects in most of these studies are attributed to mindfulness and the ability to 'let go,' or surrender, conscious intention to a greater, universal sense of self. Creative individuals often describe this process as consciously 'letting go' of unresolved problems in order to solve them unconsciously. In 2009, Horan posited that the process of surrender is part of a neuropsychological phenomenon he terms *creative contemplation*, a practice with ancient roots in some meditative traditions. Creative contemplation extends the sense of self by temporarily dissolving the self-other dichotomy. Creative contemplation doesn't limit new associations to weak or non-existent neural connections within the brain; it expands its associational influence into external reality 'as if' there were no difference between self (brain) and other (world). Horan suggested that this transcendent-integrative connection is attentional (intentional) in nature and exists in higher creativity and certain meditative states.

Chaos models could account for an intention's apparently discontinuous, acausal influence on the physical world if it operated (consciously and/or unconsciously) as a strange attractor, a fractal entity which evolves over time and incorporates self-world information into new emergent patterns. A fractal structure could potentially give serendipity (and synchronicity) an appearance of discontinuity or acausality. Intention, as an attractor, would be subjected to natural evolutionary processes both within and outside the brain. It must compete with other intentions, and noise, thereby making the overall self-world connection effect quite small. Though serendipity and synchronicity have noticeably small effect sizes, they could conceivably be magnified over time through persistent creative effort.

Another interpretation of intention's potential effect on space-time events was suggested by the work of David Bohm. In 1980, he posited the implicate order, a deep universal structure in constant flux from which space-time, quantum, and classical events emerge like vortices in a stream (the explicate order) and wherein no sustainable distinction between thought and matter exists. Bohm's implicate order parallels Jung's collective unconscious consisting of subtle archetypes, or psychic behavior patterns, embedded in the universal mind as themes or images which are mirrored in external reality via

physical processes in the brain. Archetypes, like intentions, carry psychophysiological energy and may trigger, or be triggered by, synchronistic events. They provide the alphabet of metaphor and comprise the symbolic relationships found in dreams, myths, legends, cultural icons, and much serendipitous discovery.

Bohm's theory did not receive much acceptance in the physics community. His ideas did highlight the fact that physicists get different statistical results each time an atom is measured, suggesting some additional process is at work. Walker, using information theory, proposed that human will capacity, estimated at 60 000 bits per second, acts not only directly on the physical body but nonlocally on external physical reality. He calculated that will's influence is small within the brain due to a low signal-to-noise ratio which disallows most individuals from distinguishing will from other thought processes in the brain. Consequently, individuals don't experience a complete efficacy of will.

In 2004, Stapp proposed a mechanism for the mind's ability to alter physical reality called the Quantum Zeno Effect, a confirmed physical effect demonstrating the influence of high-frequency repetitive attentional states on the physical state of an atom. Stapp's theory divides mind and matter according to John von Neumann's quantum interpretation in which the choice of question physically affects the system being addressed.

The main contention with a quantum interpretation of a serendipity effect is decoherence, nature's tendency toward closure. In the complex, thermal/chemical fluctuating environment of the brain, quantum coherence is so fleeting and extremely localized that any potential effect in the brain (much less externally) is canceled. What is overlooked in decoherence theory is that thermal/chemical fluctuations themselves are indeterminate quantum processes. Rosenblum and Kuttner also remind us that decoherence is the probability of what one might expect, or find, not what actually exists in physical reality. Consciousness becomes unavoidable.

In 2009, Ryser posited that even if individuals could intentionally manipulate the indeterminacy of their brains and bodies, the indeterminacy of external reality is influenced solely by the universal mind. This concept corresponds with both historical accounts of paradigm-shifting creativity arising from the universal mind of God and modern research on the power of intentional surrender to influence physical reality. If unconscious intention can influence incubation and illumination as well as apparently random occurrences of meaningful external events, then the presence or absence of conscious intention may not be the distinguishing factor in serendipity, or in its relation to synchronicity. What may uniquely identify serendipity is the creation of new meaning by operator-induced insight and sagacity.

Conclusion

Walpole's legacy continues to intrigue the scientific community. A careful reading of his letter to Mann and the tale of the *Three Princes of Serendip*, sheds further light on the phenomenon of serendipity and its relation to other meaningful coincidences like synchronicity. Whether serendipitous chance is considered determinate as in chaos theory or indeterminate as

in quantum theory, the consensus is that nothing about serendipity is truly accidental. From the deterministic perspective, hidden variables within nature are involved while in the quantum view, the consciousness of the observer influences serendipitous chance. The sagacious, creatively prepared mind, acting via an operator allows for insight to occur. This process is a form of abduction. Scientists who experience serendipitous discovery, are not only sagacious and creative, the constraint of objectivity permits them to investigate unusual phenomena free of preconceived notions whereas artists tend to incorporate serendipity as part of their subjective expression. The role of conscious intention in differentiating types of serendipitous discovery and its relation to synchronicity is challenged by the possibility of unconscious creative intention influencing the manifestation and interpretation of apparently random meaningful events.

Anne Sexton in Library. Used with permission from CORBIS/Bettmann.

With a high school diploma in one hand and no college degree in the other, ANNE SEXTON became one of the most famous and respected contemporary poets of her time. She began writing poetry in 1956 after watching a lecture on television about writing a sonnet. She propped up a typewriter and confidently began to write. From then on, Dr. Martin Orne, with whom she had just started psychiatric treatment following a suicide attempt, cultivated her identity as a poet as a way of recovering from the emotional instability that had led her to attempt suicide. Soon she would bring dozens of poems into her therapy sessions where she obtained the strength and encouragement she had lacked in her upbringing. Throughout her lifetime, Sexton received accolades from the most prestigious universities in the world such as honorary doctorates and Phi Beta Kappa keys from Harvard, Radcliffe, Tufts, and many more. She was praised by a myriad of literary societies including the most notable—the Pulitzer Prize for her book *Live or Die*. She received travel grants, Radcliffe fellowships, and eventually became a regular instructor at Boston University—an accomplishment she was very proud of. She performed and read her poetry at readings all over the United States and England. Sexton spoke before Auden in a British event and with the most noted poets of her day. She took workshops with Robert Lowell, W. D. Snodgrass and John Holmes; and she was privately tutored by notable mentors. She had her own musical group backing up her rhymes, called *Anne Sexton and Her Kind*. When she took her life in 1974, Sexton was only 45 years old. A previously scheduled reading at Town Hall in New York City turned into a memorial service for the poet. In her eulogy, Adrienne Rich said, “We have had enough suicidal women poets, enough suicidal women, enough

self-destructiveness as the sole form of violence permitted to women.” Later, Denise Levertov wrote the Boston Globe’s obituary of Sexton: “Anne Sexton’s tragedy will not be without influence in the tragedies of our lives. We who are alive must make clear, as she could not, the distinction between creativity and self-destruction. The tendency to confuse the two has claimed too many victims.”

Childhood

Anne Gray Harvey was born on November 9, 1928, in Newton Massachusetts. She was the third of three girls; Jane was born in 1923 and Blanche was born in 1925. Her parents were Ralph and Mary Gray Staples Harvey, whom biographer Diane Wood Middlebrook described as a couple “out of a Scott Fitzgerald novel.” They lived life at the fullest in the height of the roaring 1920s. Anne’s father, Ralph was a successful businessman in the wool industry and traveled extensively.

Later when Anne would meet her husband Kayo, he too would work in the wool business and spend many days traveling—a separation that was devastating for Anne. Ralph had but one sibling, a sister named Frances. Interestingly enough, Frances tried to commit suicide when she was in her twenties. She eventually married and lived a normal life with her husband on their horse farm. But in 1975, a year after Anne had taken her own life, Frances shot herself to death at the age of 69. Middlebrook noted that Anne’s own suicide had affected Frances profoundly. Anne’s mother, Mary Gray Staples, was an only child and, as such, was raised as a little princess. She came from a prominent and popular family. As the only daughter, Mary Gray was very close to her father, Arthur Gray Staples, whom everyone called AGS.

While Anne was growing up she and her sisters did not form strong emotional ties with one another, probably because they were constantly competing for their parents’ attention. Growing up, the eldest, Jane, was Ralph Harvey’s favorite. Blanche, on the other hand, was recognized as the studious one in the family. She was the only one who went to college and who had a stable life. Tragically, Jane and Anne would both commit suicide during middle age.

As the baby of the family, Anne loved to be cuddled. She recalled feeling very lonely as a child. Family life was formal. The “girls,” as they were commonly called, had to be formally

dressed and ready to entertain at any time. Ralph and Mary Gray led a self-serving and self-absorbed life, full of parties, drinking and excessiveness. It did not help matters that Anne was fidgety, messy, and loud. She hated mealtimes and would often take her food to her bedroom. Her physical appearance and attire did not meet Ralph's demanding and impeccable expectations. She was a chatterbox and very active.

Some of Anne's happiest times were spent on Squirrel Island during the summers when the family would vacation there. It was during this time that Anne was nurtured by the women in her family other than her own mother. Her favorite great aunt was Anna Ladd Dingley, whom she called Nana. They became very close. When Anne was 12, AGS died and the houses on the island were sold. Thus, the summers at Squirrel Island ended. During this time also, Anne's parents' drinking became worse, especially her father's drinking. Their behavior was unpredictable. They could be sweet at times, but at other times they would lash out in a rage. But it was her father's drinking that most seemed to affect Anne. He was like Dr. Jekyll and Mr. Hyde. One moment he could be very attentive. At other times he would insult Anne by telling her she disgusted him with her acne scars. Nana actually came to live with the Sexton's when Anne was eleven. In 1940 Anne had a severe constipation problem and was hospitalized at the Lahey Clinic. Anne later told her therapist that this was a traumatic time because her mother had threatened to take her for a colostomy if she did not make an effort to put an end to her elimination problems.

It was also during this time that Mary Gray was away from home a lot taking care of her dying father. At some point, someone suggested that Anne be taken for psychological evaluation—probably as a response to her elimination problems and to her problems at school. But her parents ignored this suggestion. As usual, her parents displayed more interest in keeping up with their social activities rather than attending to the needs of their children.

When Anne was 13, she became interested in boys and would spend more and more time on the phone and out with her friends. This meant less time spent with Nana. One day, Nana's ear closed up and she became disoriented. She eventually was taken to a mental hospital for shock treatment.

By this time, Anne was fifteen. Her grandfather Louis Harvey had a second nervous breakdown and Ralph, Anne's father, was drinking heavily. Mary Gray spent a great deal of time trying to hide her husband's problem. Finally in 1944, Nana was taken to live in a nursing home and she eventually died in 1954 when she was 86 years old. Anne would mark the departure of Nana for the rest of her life—feeling guilty that it had been her fault, that Nana got sick because she had abandoned her. This perspective was Anne's way of showing loyalty toward Nana. This guilt would resurface when Anne herself would become a mother.

Adolescence

Although in adulthood Anne recalled her adolescence as painful and uneventful, much information suggests otherwise. She had a couple of early relationships with boys that she recorded in her scrapbooks. Her first kiss came from Michael Bearpark who would later become a psychiatrist and see Anne again in

the early 1960s during one of her visits to England. Although this first kiss was special, it would also be associated with Nana's breakdown in Anne's memory. So the kiss was also associated with betrayal. Her other good friend from adolescence was Richard Sherwood. She later ran into him while on honeymoon with Kayo in Virginia Beach. Sherwood recalls Anne as being fun to be with and very talkative. When he saw Anne again with Kayo, he remembered how happy and full of sexual energy they were.

During the eighth grade, Anne had a steady boyfriend, Jack McCarthy. He was very much liked by Mary Gray and Sherwood and they hoped that she would eventually marry him. McCarthy remembered Anne as an extraordinary person—open about her feelings and energetic. They socialized a great deal and Anne was very flirtatious with other boys around him. Although McCarthy remembered Anne as pretty normal he did recall one incident that he found somewhat disturbing. One night, the couple had a date to go sledding behind Anne's house. McCarthy was late, but when he arrived at the house, Anne was not there. He found her at the bottom of the hill unconscious and bleeding. When he brought her inside the house, he realized that the blood was Mercurochrome and that she had faked passing out. She had dramatized her own death and rationalized it by telling him that it was a good joke on him. Early on, Anne displayed an obsessive curiosity with death. This incident marked the beginning of a long trail of experiments with death.

During her teens, Anne was seen as "boy-crazed." So her parents sent her to Rogers Hall, a boarding school. Again, while Anne would recall a lonely past, her yearbook portrayed a normal and even popular teenager. She was captain of the cheerleaders and was on the swimming and basketball teams. Most important, she directed a school play and starred in all the others. It appears that it was here at Rogers Hall that poetic seeds were planted in Anne's memory that would later save and serve her. She even published some of her poetry in the school's literary magazine called *Splinters*.

Early Writings

But it also seemed that early on in her life, her parents did not encourage her writing abilities. The first episode that scarred Anne for life was when her mother investigated the originality of one of her poems. The poem was going to be published in the school's yearbook. Prior to this, Anne's sister Jane had plagiarized and one of Anne's friends had been expelled from school for doing the same thing. Mary Gray, distrustful that her daughter Anne was also plagiarizing, sent the poem to a professor in New York for validation. The professor said that it looked like an original piece and that it showed a lot of promise. Anne was devastated and discontinued writing poetry for the next 10 years. It was clear from the scrapbooks that Anne kept during her high school years that she was expected only to find a husband and not to achieve academic success. Later on when Anne started publishing her first poems, she thought again about becoming the writer in the family. Her mother, Mary Gray, had the reputation of being the family writer—a reputation which perhaps led her to envy her daughter's achievements in high school. But Mary Gray was no writer.

Anne's second great parental disappointment came when she published poetry in the *Christian Science Monitor* and her father compared her writing to that of Mary Gray's. He said that the "girls" were creative, but that Mary Gray was brilliant.

Marriage and Motherhood

In May of 1948, while planning her wedding to a young man, Anne met Alfred Muller Sexton II, better known as Kayo. Three months later, the couple eloped. They married on August 16 in Sunbury, North Carolina and honeymooned on Virginia Beach. Kayo came from a wealthy Bostonian family. His parents were George Sexton and Wilhelmine Muller, whom everyone called Billie. He was born the same year as Anne Sexton, in 1928, and Kayo's younger sister, Joan, was born in 1931. It is perhaps of no surprise that Kayo would marry Anne. As children and into adolescence both Kayo and Anne lived with alcoholic fathers and with mothers who desperately tried to control their husbands' addictions.

In the beginning, Anne Sexton's relationship with Kayo was intense, happy, and sexually fulfilling. Sexton tried hard to become a good housewife while Kayo continued taking pre-medical courses at Colgate University. But he dropped out of school in order to begin a more serious and mature life with Sexton. He got into the wool business as a salesperson. Sexton became good friends with Joan, her sister-in-law. They eventually moved in to Kayo's parents' house where Sexton began to display some interesting personality traits, such as throwing temper tantrums when her mother-in-law would ask her to do something simple. But from the start, Sexton had not made a good impression on Kayo's mother Billie. The first time they met, right before the couple was married, Sexton shocked Billie with her bright red lipstick and chain-smoking. Motherhood and couplehood presented a variety of complications for Sexton. In 1953 Sexton had her first daughter, Linda Gray. In 1955 she had Joyce (Joy) Ladd. She found it impossible to care for her children and herself while Kayo traveled on business. She would go into deep depressions and rage at her eldest, Linda. After Linda's birth, she was diagnosed with post-partum depression. Shortly after Joy's birth, Sexton tried to commit suicide. This led her to Dr. Martin Orne who became a major player in Sexton's life.

Emotional Disorders and Treatment

When Dr. Orne first met Sexton, he asked her what she could do to have an identity in the world. Sexton could not think of anything to say except that she could possibly become a prostitute.

In the 1950s when Anne Sexton first showed dramatic signs of mental disturbance, the treatment of emotional disorders was rudimentary in the United States. When Sexton first resorted to mad suicidal gestures to display a formerly hidden anguish, the treatment available to her was limited. When she first entered treatment with Dr. Orne, she had been a housewife and mother, living in the suburbs of Boston. She was embedded in the Massachusetts conservatism that in the 1950s was at its height of sexism. Sexton with her constant

agitation was never noted as in any way out of the ordinary until she overdosed with sleeping pills. Her first suicidal gesture seemed like a hysterical play. Soon after marriage to Kayo, who became a traveling salesman like her father, Sexton unleashed her frenetic and manic temperament while her husband was on the road. She had brief sexual affairs in which she sought to have her hand held through the night. Being alone was intolerable. She commented that she didn't particularly like having affairs but that she needed "action." She manically defended against an inner emptiness generated by a sealed off early abandonment trauma. During her husband's regular absences, Sexton would stay up all night and listen to music, drink, and have drunken sex. After Kayo returned from his trips she would be temporarily all right. But she could not even cook a simple dish when he was away. One of Sexton's romantic infatuations led her to precipitous wish to leave Kayo. Both her mother and mother-in-law told her to drop her newfound love and commit to Kayo. It was then that Sexton grasped control through masochistic self-destruction. She, who feared her mother-in-law and who craved the attention of her own narcissistically self-absorbed mother, struck out in the mode of the impotent. Sexton very dramatically took a load of pills and began to vomit. This was a defiant reaction to the two mother figures. Her suicide attempt was impulsive—like a tantrum. This dramatic gesture was to be the precedent for a long line of suicidal acts that ultimately ended in the last and fatal deed. The family wished to forget, but Sexton's entrance into motherhood caused new seismic tremors. Sexton began to act totally out of control toward her older daughter, Linda. One day, at the sight of Linda putting feces in the back of a toy, Sexton threw Linda across the room. Later in a fight with Kayo, it would be her typewriter that she heaved across the room. Both Linda and the typewriter were extensions of herself. Sexton attacked Kayo by attacking herself, the writer in her who was symbolized by her typewriter. Sexton may have attacked Linda to disown that recalcitrant part of her inner being who wished to smear feces on her own mother when she had been so rigid about Sexton's constipation problem as a teenager. Despite all the years she would spend subsequently seeing therapists, nobody was ever to inquire into all this in an effective way. Sexton could rage at Linda like she could never have raged as a child because it would have been too threatening to her bond with her narcissistic mother. If Sexton didn't risk revealing her rage as a child, perhaps it was because she feared that her mother would turn away from her with contemptuous indifference. Sexton's terror of abandonment from a mother who was competitive, self-absorbed, and emotionally distant must have been incessant. Sexton's inability to form a healthy emotional and psychological bond with her mother must have severely impacted her ability to mother her own daughters.

From an object relations perspective, Sexton did not receive the proper treatment to her mental illness, which ultimately led to her own death. In a world without object relations theory and Melanie Klein, Anne was an example of the borderline personality. When Dr. Orne first treated Anne for her suicide attempts, he did not practice the standard psychiatric approach to hospitalization of those days. Due to him, her 8-year treatment stands as a fortunate contrast to that of Sylvia Plath, who received multiple volleys of electric shock. Sexton's

treatment was the exception to the rule. Dr. Orne prescribed some electric shock and a five times a week psychotherapy regime—an extreme exception for American psychiatry. At that time, Orne had been influenced by some education in psychoanalysis. Although not trained as a psychoanalyst, Orne had knowledge of Freudian psychoanalytic theory and of some clinical theory that enabled him to think in terms of the interaction of genetic history and transference. He also knew about the standard defense mechanisms. Dr. Orne's five times a week engagement with Sexton during her early hospitalization at the Weston Lodge allowed Sexton to experience his presence, no matter how closed off she was by her dissociated and unintegrated psychic state. It is unfortunate that during later hospitalizations, Dr. Orne would not be with Sexton in this way. It appears that his counter-transference anger had by then got the better of him, as he did not know not to use and process such interactions in order to enable him to understand Sexton's internal world and its compulsion to perpetually repeat its drama. It appears that Dr. Orne gradually began to use hospitalization as a punishment.

But at this early stage of their contact, Dr. Orne was quite involved with observing all of Sexton's manifold incarnations. She was a chameleon becoming whomever she conversed with. Viewing this as a hysterical dynamic, Dr. Orne was not totally out of his depth when Sexton began to speak schizophrenic language. Not believing that she had a thought disorder, Dr. Orne removed Sexton from the schizophrenic ward and her language transformed back to normal. He noted her schizophrenic language induced by imitating others, as she merged with others to find an identity. He viewed this as part of Sexton's hysteria. Sexton's ability to so purely imitate, to model herself on others so quickly and thoroughly, can be related to a borderline hysterical dissociation, not to a neurotic hysteric's mode of repression. Dr. Orne did not make these distinctions.

Sexton lacked the subjective *I*. She was not in herself, not in her body. She inhabited the paranoid-schizoid state of mind most of the time, a state of mind in which reactive reflex and reenactive reflex dominate the scene, rather than reflective thought. Dr. Orne did not understand the core schizoid level of Sexton's hysteria—the borderline preoedipal condition and its need for in-the-moment contact in treatment. He didn't understand that Sexton's chameleon mode of identification with anyone near her indicated a core lack of subjective self-identity and a borderline dissociation process as differentiated from neurotic hysteric's mode of repression that is founded on adequate preoedipal development. Dr. Orne attempted to uncover her memories and history as in sessions in which she reported incest and sexual abuse from her father. He helped her discuss her lies and distortions, in relation to her memories. Yet the true memory lived in the moment—he did not tune into this.

One common aspect of Sexton's behavior was to go into trances. With Dr. Orne these trances would occur at the end of many sessions. Her sealed-off yearnings for connection, often manifested by body cravings or by an incorporation process in her mind, threatened to emerge through a pressured trance state, but they were warded off by emotional distancing during the therapy session. She became paralyzed at the end of each session, unable to leave and separate. She had not gotten what

she needed in the session, the emotional contact and connection she required. The terror, need, blocked rage, and pain were contained in the state of trance.

During one session, this splitting process threatened to form a multiple personality. Unacquainted with borderline splitting, Dr. Orne was unequipped to deal with the phenomenology of a split-off personality appearing in the therapy session. Hoping to prevent Sexton's transition into a multiple personality, his response was to ignore the created personality whom Sexton called "Elizabeth." He said that when he ignored Elizabeth, she went away. Dr. Orne thought he had stopped a pathological process. According to Sexton, however, Elizabeth was a little bitch. This bitch-witch part of her was the one that was erotically engaged in a sadomasochistic struggle with her father. Her father had become her demon lover when he spanked her and aroused her erotically. She wrote a poem for Dr. Orne titled "The Royal Strapping." Through the poem, Anne told him how her father had stripped her naked on his marriage bed and beat her behind with her own riding crop, just after she had returned from horseback riding. But the poem was never consciously experienced in the session, neither by Dr. Orne nor by Anne Sexton.

One of Sexton's best friends was the poet Maxine Kumin, whom she met at a poetry workshop by John Holmes. The two women had many things in common and they quickly became good friends—sharing poetry as well as dresses. Kumin, however, was well recognized in the poetry scene by the time she met Sexton. It appears that Kumin's successful status as a poet served Sexton well in terms of motivation and good role modeling. The first time Sexton shared a poem with Kumin—the poem "Music Swims Back to Me"—Kumin praised and encouraged Sexton.

Sexton eventually became a published and well recognized poet herself. In her personal life however, she did not make progress. The mere presence of her daughters living at home with her disrupted and threatened her emotional well-being. As a result, Joy lived most of her early years with her paternal grandmother, Billie. Linda lived for a short while with her Aunt Blanche and Blanche's husband Ed. Although Linda lived with them a short while, she remembers this period of her life as an eternity. Unfortunately, Linda continued to suffer physical and emotional abuse from her Uncle Ed who would torture her with his leather belt and his lashing tongue.

As a result, Sexton spent very few years with her daughters, which affected the entire family. Billie seems to be the rock that kept the family together, but at a great cost. Having Billie pick up the pieces meant that Sexton had the freedom to manipulate and control as much as she wanted. Middlebrook noted that Joy was grateful for Billie's presence and mothering, however. Linda Gray made the same observation in her own autobiography. Soon problems with Kayo began to arise due to Sexton's compulsion with poetry. Conferences, workshops, and trips would interfere with Kayo. Mixed in with her mental instability, Kayo found Sexton's new life intolerable. When he was around, they would get into horrible drunken fights in which they would both physically attack each other. Many of these happened in the presence of their daughters who would later have to explain to the police what had transpired.

No doubt that Sexton lived with a horrible fear of abandonment, which had existed since her childhood days. The feelings

of being abandoned continued into adulthood. Anne lost Dr. Orne who took a job out of state. She eventually divorced Kayo, and her daughters went away to boarding schools or college. Sexton's psychiatric treatment continued with a series of other doctors who just could not seem to help her. She became addicted to sleeping pills and alcohol. One of the most documented and alarming situations was Sexton's affair with one of her therapists, Dr. Ollie Zweizung. Breaching one of the cores of the patient-doctor relationship, Dr. Zweizung did not seem to understand the damage he would cause Sexton with his breach of boundary.

The last therapist Sexton saw was Barbara Schwartz. Nine months after she started seeing Schwartz, Sexton went to her scheduled appointment. It was October 4, 1974. She brought with her a poem she had written for Schwartz about a female therapist who took a young schizophrenic patient through a symbolic gestation and rebirth. Sexton had apparently felt a sense of gratitude toward Schwartz for the 9 months of therapy she had given her. Schwartz did not see the poem or Sexton's behavior as a form of saying good-bye until she noticed that Sexton had deliberately left her cigarettes behind—something Sexton would never do. Later that day, Sexton had lunch with Kumin who was getting ready to take a long trip with her family to Europe. After the lunch, Sexton went home. After having a drink of vodka, she took off all her rings, and put on her mother's

fur coat. She went to the garage; got in her car; turned on the radio and started the engine. On this night Anne Sexton experimented with suicide for the last time and ended her own life.

It was evident from the amount of documentation that Sexton left behind that she led a troubled life. Unable to cope with the demands of motherhood, Sexton lived torn between being a bad mother and wife, and being a great poet. The two lives could not coexist. She had once told Dr. Orne, "You see, I've taken care of that 'life' part by writing poems." This quote could not better describe Sexton's feelings for wanting to be a complete human being with a unique talent. But amid all the turmoil in her life, she was able to work every day. She was able to love her daughters as is depicted in Linda Gray Sexton's own autobiography *Searching for Mercy Street* where she quotes a song that her mother had written for her: "Night-night time has come for Linda Gray, Night-night time, the same time every day, It's night-night time, It's night-night time, night-night time has come."

William Shakespeare 1564–1616

English dramatist, poet, and actor

Author of 37 plays 154 sonnets

D K Simonton, University of California, Davis, CA, USA

© 2011 Elsevier Inc. All rights reserved.

This article is reproduced from the previous edition, volume 2, pp. 559–564, © 1999, Elsevier Inc.

WILLIAM SHAKESPEARE created a body of plays and poems that are considered among the greatest in English literature. The plays include tragedies, such as Hamlet, Othello, and King Lear, comedies, including Much Ado about Nothing, As You Like It, and Taming of the Shrew, and histories, such as Richard III and Henry IV, Parts I and II. Besides the collection of sonnets in Elizabethan form, Shakespeare wrote two heroic narrative poems, Venus and Adonis and The Rape of Lucrece. Often given the byname Bard of Avon or Swan of Avon, Shakespeare's literary creativity has shaped immeasurably the vocabulary, imagery, metaphors, and modes of expression in the English language. His best plays are often judged as among the greatest in any language, ancient or modern. Shakespeare is frequently seen as the prototypical literary genius.

Life

For a creative genius of his stature, the biographical information about Shakespeare's life is surprisingly meager. We know that he was born in Stratford-upon-Avon, on April 23, 1564, where he presumably was educated at the local grammar school. At 18 he married Anne Hathaway, from the same town, who bore him three children, a daughter Susanna and the twins Judith and Hamnet. A couple of years later, he began to attain success as a playwright in London, where he became a member of the Lord Chamberlain's Company, London's leading theater group. Shakespeare prospered sufficiently that he could retire to his birthplace, living out his final years as a country gentleman. He died in Stratford-upon-Avon on April 23, 1616, and was buried in the parish church. Only a

month before, Shakespeare had made out his will, famous for the passage in which he left his wife the "second-best bed" in the house. Only a handful of largely impersonal legal documents and miscellaneous notices add any further details to this biographical sketch.

The sparseness of the biographical information has led a number of dissenting scholars to argue that Shakespeare was not the true author of the works that currently make up the canon. Among the candidates put forward are the essayist and philosopher Francis Bacon, the dramatist Christopher Marlowe, Edward de Vere, the 17th earl of Oxford, and William Stanley, 6th earl of Derby. These rival claims are often predicated on the belief that the true author must have had a higher social standing and a better education than that enjoyed by Shakespeare – an assumption that may reveal more class prejudice than a genuine understanding of creative development. Moreover, advocacy of these alternative candidates must overcome a host of factual difficulties of their own. Marlowe, for example, was killed in a tavern brawl in 1593, before Shakespeare began to produce the major plays on which his reputation rests. Just as important, more than four dozen contemporaries testify to Shakespeare's authorship, including his fellow actors as well as his fellow playwright, Ben Jonson. It is always possible that some authentic document will someday be found in some dusty archive that proves once and for all that someone else wrote the plays and poems. But until that day arises, the best conclusion to draw is that the traditional attribution is the correct one.

In any case, given how little is known about the man, it is clear that if we wish to understand Shakespeare's creativity we must turn from biography to the creative products that have earned him such an exalted place in world literature.

Works

Shakespeare's two large poems, *Venus and Adonis* and *The Rape of Lucrece*, were both written relatively early in his career, the first appearing when he was 29 and the second when he was 30. Although not without considerable literary merit, Shakespeare's reputation rests most firmly on his sonnets and plays. Furthermore, these latter two manifestations of his genius are those that have attracted the most empirical research by psychologists who study creativity.

The 154 Sonnets

Shakespeare's sonnets were published in 1609, when the poet was in his mid-40s, although most of the poems probably

date from when he was in his 30s. There has been considerable scholarly speculation about the autobiographical significance of these sonnets. The poems contain many cryptic references to various persons, including a rival poet, a dark woman, and a handsome young man. Whether or not these persons were real or imagined may never be determined. But what can be expressed with confidence is that Shakespeare managed to express strong feelings and universal themes within a tightly regulated literary framework. Almost all sonnets follow the same Elizabethan form of three quatrains and a couplet, all 14 lines in iambic pentameter and restricted to the rhyme scheme of *a b a b, c d c d, e f e f, g g*.

Although many of these poems represent some of the highest accomplishments in the history of the English sonnet, it remains true that the collection contains creations of uneven merit. Research on creativity has shown that even the greatest geniuses have days when their muses seem to abandon them, and Shakespeare was no exception. This variation in aesthetic success is evident in the differential frequency that the 154 sonnets are included in anthologies or cited in books of quotations. Content analytical studies have shown that the more popular sonnets differ in identifiable ways from those that remain in relative obscurity. In particular, the more successful sonnets treat a greater variety of themes, employ a richer vocabulary, and display much more primary-process imagery. These investigations have also demonstrated that the more popular sonnets tend to manipulate linguistic expression across the consecutive lines in highly distinctive manner. Particularly notable is the way Shakespeare designs the concluding couplet so that it provides enriched associative linkages with the preceding three quatrains. Remarkably, these characteristics of the most accomplished sonnets have been discerned by computer programs designed to tease out the content and style of literary text.

Unfortunately, it is not yet known whether these enhancing aesthetic attributes apply to other poems besides those attributed to Shakespeare.

The 37 Plays

Shakespeare wished to stake his fame on his poetry. Crafting plays, in contrast, is what he did to earn a good living—roughly analogous to writing film scripts today. Yet it is one of the ironies of his life that the dramas now probably represent his most pervasive and influential legacy to world civilization. Needless to say, not all of Shakespeare's dramas have received the same praise from posterity. Like the sonnets, the plays are not all of equal quality. For example, *Hamlet* is by far the most highly acclaimed, whereas his *Henry VI* trilogy could disappear off the face of the earth without damaging Shakespeare's reputation whatsoever. Accordingly, to appreciate better the basis for Shakespeare's creative genius, researchers have tried to fathom why some plays are more successful than others. The starting place for such empirical inquiries is the information exhibited in [Table 1](#). This lists all of the plays in the traditional Shakespeare canon (omitting only *The Two Noble Kinsmen*, which most scholars ascribe largely if not entirely to John Fletcher). Alongside each play are two key data. First are the estimated dates based on a statistical analysis of the many tentative datings of the plays advanced by Shakespeare

TABLE 1 The Shakespeare dramatic canon: production dates and dramatic popularity

<i>Play</i>	<i>Date</i>	<i>Popularity</i>
<i>King Henry VI, Part 1</i>	1591	−1.51
<i>King Henry VI, Part 2</i>	1591	−1.41
<i>King Henry VI, Part 3</i>	1591	−1.62
<i>The Comedy of Errors</i>	1592	−0.37
<i>The Tragedy of Richard III</i>	1593	0.23
<i>Titus Andronicus</i>	1593	−1.13
<i>The Two Gentlemen of Verona</i>	1593	−1.13
<i>Love's Labour's Lost</i>	1593	−0.81
<i>The Taming of the Shrew</i>	1594	0.58
<i>Romeo and Juliet</i>	1595	1.34
<i>The Tragedy of Richard II</i>	1595	−0.02
<i>A Midsummer Night's Dream</i>	1595	1.00
<i>The Merchant of Venice</i>	1596	0.98
<i>The Life and Death of King John</i>	1596	−1.13
<i>Henry IV, Part 1</i>	1597	0.27
<i>Henry IV, Part 2</i>	1598	−0.27
<i>Much Ado about Nothing</i>	1598	0.31
<i>The Life of Henry V</i>	1599	0.48
<i>Julius Caesar</i>	1599	0.55
<i>As You Like It</i>	1599	0.82
<i>The Merry Wives of Windsor</i>	1600	−0.07
<i>Twelfth Night (or What You Will)</i>	1601	0.90
<i>Hamlet, Prince of Denmark</i>	1601	2.19
<i>Troilus and Cressida</i>	1602	−0.74
<i>All's Well that Ends Well</i>	1603	−0.68
<i>Measure for Measure</i>	1604	0.34
<i>Othello, the Moor of Venice</i>	1604	1.19
<i>King Lear</i>	1605	1.36
<i>Macbeth</i>	1606	1.53
<i>Antony and Cleopatra</i>	1607	0.31
<i>Timon of Athens</i>	1607	−1.51
<i>Coriolanus</i>	1608	−0.81
<i>Pericles</i>	1608	−1.31
<i>Cymbeline</i>	1610	−0.17
<i>The Winter's Tale</i>	1610	0.19
<i>The Tempest</i>	1611	1.00
<i>The Famous History of the Life of King Henry VIII</i>	1613	−0.89

scholars. Despite the presumed disagreements, these amount to no more than “tempests in a teapot,” for an extremely impressive consensus prevails (i.e., the internal consistency alpha reliability of the datings is .999). Second are the ratings of the 37 plays according to their frequency of performance, recording, and quotation, the number of single editions and film versions, the number of operatic versions, subjective evaluations by Shakespeare experts, and so forth. These summary scores, too, are highly reliable (i.e., the internal consistency alpha is .88). To facilitate comparisons, they have been put in the form of standard scores (viz., z-scores with means of zero and standard deviations of 1). Thus, plays with negative scores are below average in merit, whereas those with positive scores are above average in merit. It is obvious, for example, that *Hamlet* stands at the very top, while *Henry VI, Part 3*, sits at the very bottom. The play *Richard II*, in contrast, may be said to represent the typical level of quality for a Shakespeare drama.

These two columns of data immediately suggest an interesting question: How did Shakespeare's dramatic success change

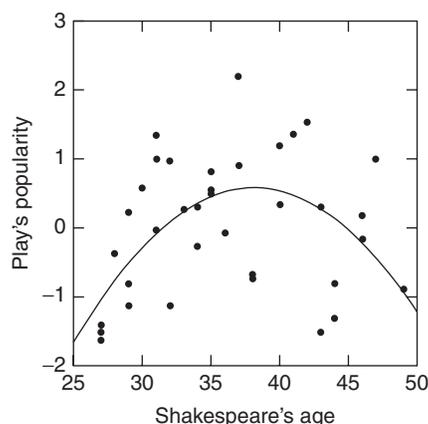

Figure 1 The curve best describing the relation between Shakespeare's age and a play's dramatic popularity. The quadratic function explains 27% of the longitudinal fluctuations.

over the course of his creative career? At first there may seem to be no clear pattern, because successful and unsuccessful plays seem to be interspersed throughout his career. Yet closer inspection suggests that many of his greatest plays appear when he was in his late 30s and early 40s, a career peak well in accord with the findings of research on the relation between age and achievement. In fact, when we fit a curvilinear age function, we obtain the results seen in [Figure 1](#). The inverted-U curve accounts for 27% of the longitudinal variation in dramatic merit, a highly impressive percentage.

Of course, there still exists considerable fluctuation around this trend line. Hence, most of the differential impact of Shakespeare's plays cannot be attributed to age alone. Nonetheless, as in the case of the sonnets, empirical investigations have managed to isolate some of the factors that discriminate the masterpieces from the also-rans. One predictor is the thematic material that is featured in the play. For instance, those dramas that treat strong human feelings—especially those that verge on madness or emotional excess—tend to gain in popularity. *Othello*, *Lear*, and *Hamlet* are fine illustrations of this effect. In addition, certain stylistic devices also make a contribution to aesthetic impact. For example, Shakespeare's output shows evidence that he skillfully employed puns in order to enhance the effectiveness of his plays. Especially fascinating is his use of puns to provide comedy relief, such as the famous Porter Scene in *Macbeth*.

Thus far we have been concentrating on the determinants of the comparative popularity of the 37 plays. But this has not been the only aesthetic attribute worthy of investigation. In fact, much research has concentrated on the factors that shape the form and content of these same dramas. Shakespeare's age, for instance, is linked with the themes scrutinized in his plays. As a young man, love themes tended to be relatively conspicuous, especially when he was in his early 30s, but gradually this preoccupation yielded to more weighty issues, such as conflict in human affairs. The contrast between *Romeo and Juliet* and *Hamlet* exemplifies this change. Other developmental shifts may be seen in his use of primary- and secondary-process imagery, incongruous juxtapositions of images, and various linguistic devices, such as the use of rhymes, prose, and

run-on lines. Clearly, Shakespeare's mode of creative expression was far from static, but rather displayed a dynamic progression over the course of his long dramatic career. In this respect, the Bard behaved just like other geniuses of the highest rank, such as Beethoven and Michelangelo. Creative geniuses seldom sit still.

The plays reveal Shakespeare to be like other great creators in yet another respect. The creative genius, no matter how grand, does not work in isolation from the external milieu. On the contrary, Shakespeare's dramatic output betrays many signs that he was ever responsive to the zeitgeist, especially in the political realm. Conspiracies against the throne, internal rebellions, and military threats from foreign powers all left their imprint on the thematic material found in his plays. For instance, when England found itself under attack by foreign military forces, Shakespeare was inspired to devote more lines to the discussion of war, conquest, and empire. The political circumstances could even exert a more direct effect on a play's aesthetic success, for the more popular works tended to come shortly after a major rebellion or conspiracy shocked the nation. The less popular dramas, in contrast, were more likely to emerge after the times had been more politically tranquil. This is also a consequence that has counterparts in the careers of other creators.

Conclusion

The foregoing review could only present the highlights of what has become a very rich research literature on the Shakespeare canon. These empirical findings have not only given us insights into Shakespeare's life and works, but have also shed some light on how creativity may operate in other writers. Indeed, if we had to pick one genius as the starting point for a more general understanding of literary creativity, it is hard to imagine a better place to start than with the Bard. He is arguably the most influential of all literary creators. After all, Shakespeare's plays are still produced on stages all over the globe and in all of the world's major languages. They have been recorded on records, cassettes, compact discs, videotapes, and full-length feature films. The plays have also been adapted, extended, or transformed in a great diversity of ways, such as Akira Kurosawa's movie *Ran* (from *King Lear*), Leonard Bernstein's musical *West Side Story* (from *Romeo and Juliet*), and Tom Stoppard's play *Rosencrantz and Guildenstern Are Dead* (from *Hamlet*). Additional reverberations of his dramas show up in cartoons, comic books, and children's storybooks as well as in tone poems, songs, modern dance and ballet compositions, puppet shows, and even kabuki theater. Shakespeare's dramatic genius has inspired more operas than any other author, classic or modern. A partial list of the operatic composers inspired by his greatness include Adam, Barber, Bellini, Berlioz, Britten, Bruch, Goldmark, Gounod, Halévy, Holst, Nicolai, Purcell, Rossini, Smetana, Vaughan Williams, Verdi, Wagner, and Wolf-Ferrari. Even the Bard's poetry has continued to sustain his posthumous reputation, albeit in a more quiet way, such as a booklet titled *Sonnets* gently tucked away in a traveler's suitcase. As Ben Jonson declared in the 1623 *First Folio*, Shakespeare "was not of an age, but for all time!"

*GEORGE BERNARD SHAW is one of the most quoted writers of the past 2 centuries. He was born in Dublin in 1856. Never a good student, he quit school at age 15 and worked as a clerk in a real estate office. His self-education in the arts flourished, and in 1876 he emigrated to London where his mother and two sisters had gone 3 years earlier. In London he made friends with a wide range of artists and intellectuals. He began writing music and art criticism, and in 1878 wrote his first novel, *Immaturity*. After writing another four novels in 4 years, he gave up this genre. He was greatly influenced by the work of Marx and other socialist writers. During the 1880s he was active in the Fabian Society, a middle-class socialist group in which he learned to debate and lecture. There he met Sidney and Beatrice Webb, as well as Charlotte Payne Townshend, whom he married in 1898. Shaw's plays became a means to express his ideas about class and his criticism of Victorian and romantic attitudes. He became well known for the polemical prefaces that he wrote to his plays. A Nobel Prize winner, Shaw wrote more than 50 plays during his long lifetime. As a playwright, critic, public speaker, and even as a politician, his influence has spread worldwide.*

Early Life in Dublin

George Bernard Shaw was born in Dublin on July 26, 1856, to George Carr Shaw (1814–1885) and Lucinda Elizabeth Gurly Shaw (1830–1913). George Carr Shaw was the second cousin of a baronet, and this status as a gentleman gave him certain privileges and invitations; however, he had no inheritance, no particular skills, and an unfortunate drinking habit that soon alienated the whole Shaw family. George Carr Shaw eventually became a teetotaler, a practice his son would later assume. Although the younger Shaw often described his father

(as well as his mother) in disparaging terms, he nevertheless acknowledged the gift of humor he received from him. In his autobiographical *Sixteen Self Sketches*, written when he was 93, Shaw described his mother as “the daughter of a country gentleman,” “brought up with ruthless strictness to be a paragon of all ladylike virtues and accomplishments by her grand aunt.” He attributed his imagination to Lucinda Elizabeth Gurly, an accomplished musician who apparently took care not to squander any passion on her family. The capacity for (or perhaps pose of) emotional coolness for which Shaw is often criticized must have been learned from his mother. George and Lucinda were not a happy couple and their home life was lacking in warmth. Given this type of upbringing, Shaw's self-reliance was learned early.

Fortunately for young Shaw there were a few maternal uncles who helped provide some nurturance and guidance. But perhaps the most important influence on him was that of George John Lee (1831–1886), his mother's singing teacher and close friend of the family. Lee was an eccentric man, short, dark, and crippled since childhood by an accident to his foot. He was a well-established orchestral and operatic conductor in Dublin who had created a method of singing that Shaw claimed preserved his mother's voice perfectly until her death at over age 80. Lee offered music to the Shaws, as well as the vitality of fresh ideas. Lee and the Shaws united households in 1863 when the two families moved into a four-storey house at Number One Hatch Street. Shaw loathed school. He quit school at age 15 and became a junior clerk in the Charles Uniacke Townshend land-agency office. Meanwhile, the household was filled with music rehearsals and lessons of Lucinda Shaw and George John Lee, and young Shaw had an excellent ear for music. He also spent hours studying the masterpieces at the Dublin National Gallery and enrolled in free-hand classes in the Royal Dublin Society's School of Art. He was an avid visitor of the Royal Theatre, and he read Dickens, Scott, Shakespeare, Bunyan, the Bible, and much of the contemporary popular literature. Shaw's work at Uniacke Townshend was a source of boredom for him, but he did his job well. In *Sixteen Self Sketches*, he wrote that “my desk and cash-box gave me the habit of daily work, and taught me that I must learn to do something instead of daydreaming, and that nothing but technical skill, practice, efficiency: in short, mastery, could be of any use to me.” Thus, we see the beginnings of a most remarkable self-discipline that would result in Shaw's prolific output through his long career.

In 1873 the Shaw-Lee household broke up when Lee's musical career became so successful that he changed his name to George John Vandeleur Lee and ambitiously left Dublin for

London. One month later, Mrs. Shaw sold the Hatch Street House, sent her husband and son to a nearby boarding house, and with her two daughters followed Lee to London. Young Shaw soon became restless in Dublin, and in 1876 he resigned from his job at Uniacke Townshend and moved to England.

Shaw's Apprenticeship in London

Shaw arrived in England just 4 days after his sister Agnes died of consumption on the Isle of Wight. He stayed there with his mother and sister Lucy for a month before the three of them then moved to London. Shaw notes in his diary that he was "unoccupied" during his first months in London. He was shy and awkward at this time. Although he was not certain where his talents would take him, he claimed many years later in the preface to his first novel, *Immaturity*, that "as the English language was my weapon, there was nothing for it but London." He began to ghost-write articles for *The Hornet* and he continued to study music, French, and Italian.

In 1878 Shaw undertook three serious literary efforts. He began *My Dear Dorothea* in January. This short piece (approximately 4200 words) is a fictional letter of advice to a 5-year-old girl, Dorothea. It was intended to be the first of a series of letters on moral education, but no other letters of the proposed series have ever been found. *My Dear Dorothea* was published posthumously in 1956. Shaw's most important advice to Dorothea is that she "always strive to find out what to do by thinking." He warned that thought will bring self-insight, and that this insight may be disappointing. In this early effort one can see the emergence of Shavian form and content: humor, paradox, moralizing, the use of the letter as a means of expression, a female as the main character, and many inchoate ideas that would later become major themes of Shaw's work. *Passion Play*, a satirical drama in verse form, was begun in February 1878 and never finished. In this play Shaw continued to develop some of the themes from *My Dear Dorothea*. Also written in 1878 was an outline for a novel, which Shaw never completed, called *The Legg Papers*. In March 1879 Shaw began his daily habit of writing every day. He submitted about a dozen essays to numerous publications. Two were accepted: "Opera in Italian" and "Christian Names." He read books at the British Museum on etiquette so that he could accept invitations from his sister's friends (as well as from associations he met through Lee). Gradually, he developed self-confidence. During this same year he began working for the Edison Telephone Company at a position that required him to persuade reluctant people in the east end of London to erect telephone poles on their property. He was promoted twice, but he eventually gave up the job in order to devote all efforts to writing. During the next 5 years he completed five novels, none of which were successful.

London in the 1880s was a good place to stimulate Shaw's curious mind. The ideas of such thinkers as Darwin, Marx, Spencer, and the Mills created an intense intellectual climate in which people could discuss and argue scientific, social, philosophical, and political issues. During this time Shaw became a lifelong believer in vegetarianism. He joined the Land Reform Union and the Fabian Society, both of which were middle-class socialist groups.

In 1885 Shaw began writing *Widower's Houses*, in collaboration with his friend William Archer. Archer, who had known Ibsen personally, had translated some of the Norwegian playwright's work, and around that time Shaw became familiar with and deeply impressed by Ibsen's social criticism. In 1891 Shaw wrote *The Quintessence of Ibsenism*, championing Ibsen's plays of social purpose. *Widower's Houses*, which Shaw would later complete on his own, was an attack on the practices of slumlords in Victorian England. It was produced in 1892, with little success, and eventually published in his *Plays, Pleasant and Unpleasant* (1898).

Shaw had come to feel that people should attend the theater in order to face unpleasant facts rather than to be entertained. The four "pleasant" plays in this collection, comedies with serious themes, are *Arms and the Man*, *Candida*, *The Man of Destiny*, and *You Never Can Tell*. The "unpleasant" plays (in addition to *Widower's Houses*) that deal with class injustice and sexual morality are *Mrs. Warren's Profession* and *The Philanderer*.

Shaw in The 20th Century

Shaw went on to write *Plays for Puritans* (1901), which included *The Devil's Disciple*, *Caesar and Cleopatra*, and *Captain Brassbound's Conversion*. Declaring himself a puritan in the broad sense of adhering to the dictates of conscience, he wrote these three plays as studies of conscience. In these plays he continued to see the stage as a means of social criticism on which he could broadcast his belief in the evils of capitalism, romanticism, and traditional morality. Other famous plays include *Major Barbara* (1905) and *Pygmalion* (1913), both of which were eventually made into motion pictures. Shaw's *Heartbreak House* (1917) is a somewhat pessimistic portrayal of disillusionment and ends with the outbreak of World War I. His monumental *Back to Methuselah* (1921) is a five-play collection that explores human progress from Eden to a science fiction future. In *Saint Joan* (1923), Shaw created a heretical Saint Joan of Arc whose brilliant monologues make the play one of his most popular. He was awarded the Nobel Prize for literature in 1925.

Shaw continued to write plays and prefaces, as well as other works of fiction and nonfiction, into his 90s. His *Common Sense about the War* (1914) and *Everybody's Political What's What?* (1944) are critiques of society in general and Britain in particular. *The Intelligent Woman's Guide to Socialism and Capitalism* (1928) echoed many of the feminist themes of his earlier plays. The novella *The Adventures of the Black Girl in Her Search for God* (1932) describes Shaw's creative evolution and the idea of the "life force," or the energy of progress. According to Shaw, the life force was a metaphor for a universal will that each individual has and that strives to improve the human race. Shaw died on November 2, 1950, in his country home at Ayot St. Lawrence.

The Evolving Systems Approach to Creativity and Generalizations About the Development of A Creative System

One way to study creativity is the evolving systems approach, a method constructed by Howard Gruber and his associates.

A creative individual is an evolving system that regulates creative activity, which in turn regenerates the system. Creative thought is a product of such a system and occurs as a constructive process involving a series of changing and growing structures. The creative system evolves through the interaction of three interrelated subsystems: purpose, knowledge, and affect. Organization of purpose refers to the way a person orchestrates his or her activities to achieve optimal work. The creative person pursues a network of enterprises that is crucial to his or her productive life. Organization of knowledge refers to the structures of the creative individual's thought—that is, creative thought does not imply one great moment of insight. Rather it involves a stable, repetitively functioning system whose thoughts evolve over time in many enterprises. A third subsystem, organization of affect, refers to the feelings that occur when a person is being creative or functioning optimally.

Can any generalizations be formed from the life of George Bernard Shaw and the lives of other creative people like him? One generalization may be that creative people at some time early in their careers set up a scaffolding on which to further develop their ideas. For example, *My Dear Dorothea* shows that the style and content of Shaw's later work was present in his early work. This short work may have provided for Shaw what Gruber and Davis have called an "initial sketch the rough draft or early notebook to which the worker can repair from time to time—that serves as a sort of gyroscope for the oeuvre."

An initial sketch should not, however, be mistaken for the later work. The sketch provides a direction for the creative system, perhaps a reminder of or commitment to the initial sense of purpose. For instance, Shaw did not simply discover the idea of creative evolution by reading Samuel Butler, nor did he somehow pick up ideas about class injustice by reading Marx. These ideas were constructed through repetition and variation of structures, beginning with such early works as *My Dear Dorothea* and progressing through the novels, plays, letters, and essays. In *My Dear Dorothea*, the rudiments of Shaw's life philosophy are many and stimulating, but a close look shows this work to be a first draft, an experiment of the life force, with tenuous arguments to be developed and perfected by the author for the rest of his life. The construction of a creative work, for instance, Shaw's *Back to Methuselah*, was a result of years of struggling with and debating about some of the themes in *My Dear Dorothea*. Gruber and Davis cited the examples of Darwin, Piaget, and Picasso, in which each of these creative people made initial sketches that provided a guide for later work.

Another generalization may be what Gardner and Wolf call "asynchrony" in the life and work of a creative person. They define several levels of creativity: neurobiological, cognitive, affective, domain, and field. The neurobiological, cognitive, and affective levels have been more thoroughly researched than the levels of domain and field. Domain refers to one's organization of knowledge within a particular area, craft, or discipline. Field is a sociological concept that refers to the people who work in a particular discipline, and the agencies, institutions, and reward systems that motivate and govern the discipline. Outstanding examples of creativity tend to emerge not when there is synchrony between or among these different levels, but when there is an asynchrony. The asynchrony may be

a discordance or tension, some kind of conflict that motivates the system to construct something new. Gardner and Wolf hypothesized that the lives of creative individuals may be characterized by asynchrony not because it *plagues* them, but rather because they *seek* it. This notion is similar to Hudson's (1966) finding that crisis seeking is characteristic of original thinkers and the correlation that Barron (1963) found between attraction for disorder and originality. Arlin (1984) described a postformal process by which problem-solving operations are replaced by problem-finding operations.

There are many examples of asynchrony in Shaw's life. His family were Protestants in a predominantly Catholic country. George Carr Shaw's adequate income was asynchronous with the high social rank that he claimed. Bernard Shaw was motivated to leave Dublin at the age of 20 and spent the rest of his life as an Irishman in England. His organization of knowledge was characterized by constructive opposition in which he created asynchronies. Gardner and Wolf hypothesized that "perhaps [creative people's] temperament is such that, constitutionally dissatisfied with the status quo, they are perennially predisposed to up the ante, to stir up troubles, to convert comfortable synchrony to tension-producing asynchrony."

In *The Quintessence of Ibsenism*, Shaw wrote that "every step of progress means a duty repudiated, and a scripture torn up." How does a creative system know when to construct from a foundation by modifying an earlier work and when that foundation should instead be "repudiated" or "torn up"? In other words, if a creative system seeks asynchrony, when is this asynchrony appropriate to creative work and when does it become counterproductive? A meaningful life is guided by a network of enterprises that enables the system to make the best use of time and energy. A purposeful life is guided by a network of enterprises that regulates the important need to tear down and rebuild. Thus, Shaw's iconoclasm was not destructive, because he did not randomly annihilate but instead carefully chose his targets and offered solutions. For instance, his disgust with poverty and the economic system that he felt created it should be replaced by socialism. The mindlessness of organized religion should be replaced with a belief in creative evolution. Rather than intoxicating theater goes with romantic escapism, he offers the realism of moral fiction.

Another generalization derived from Shaw's life is that creative people are likely to be creative in more than one domain. Shaw attended art school in Dublin and was a self-trained musician. He was fascinated with photography, and his last completed work is a small book of photos he took and rhymes he made about his home at Ayot Saint Lawrence, *Bernard Shaw's Rhyming Picture Guide to Ayot Saint Lawrence*. Shaw saw the advent of cinema as an opportunity to transfer his plays to a medium that would be available to a larger audience. (But Shaw did not appreciate the fact that cinema has a dramatic technique of its own and insisted that motion pictures must be filmed theater.) Hjerter (1986) has compiled a picture book of the art of more than 50 writers—for example, William Blake, Charlotte and Emily Bronte, Ibsen, Faulkner, and Harriet Beecher Stowe—who were also talented visual artists. A creative system again depends on a network of enterprises that is organized for optimal use of time and energy. A creative system intelligently chooses which talents, or enterprises, to pursue and which he or she may not have time or energy to pursue.

Finally, it is apparent from work with the evolving systems approach that creativity must be seen in a larger system, that a creative person does not function in a vacuum. Collaboration was an important theme in Shaw's life. A prolific writer, he wrote thousands of letters. Many of these were published, for example those to the English actresses Ellen Terry and Mrs. Patrick Campbell. Shaw was well aware that creativity does not spontaneously generate itself. As he wrote in the preface to *Major Barbara*: The body of thought is the slowest of growths and the rarest of blossomings [and the] conception of clever persons parthenogenetically bringing forth complete original cosmogonies by dint of sheer 'brilliancy' is part of that ignorant credulity which is the despair of the honest philosopher, and the opportunity of the religious impostor.

Glossary

Extrinsic motivation Being moved to perform a task from the outside, because of external rewards such as money or fame.

Intrinsic motivation Being moved to perform a task from the inside, because it is a source of passion and gives pleasure and satisfaction.

Labeling theory The view that a phenomenon is not intrinsic to an act or person, but a label given to that act or person by a majority or a significant group of 'gatekeepers' (e.g., art critics, gallery owners).

Methodological holism An approach to research that takes the social system as the unit of analysis.

Methodological individualism An approach to research that takes the individual as the unit of analysis.

Expanding PPP: Person, Process, Product

The research on creativity that emerged in the 1950s and 1960s was initially organized around 3Ps: Person, Process, and Product. In the images of creativity popularized by Hollywood, the lone tormented genius is the exemplar of the creative *person*, the comic book image of the creative *process* is the light-bulb going on over a person's head accompanied by a cry of Eureka!, and the Product is inevitably the earthshattering discovery in the sciences or the sublime creation in the arts that will stand the test of time. In all three popular images and in the initial research that started in the 1950s the unit of analysis in thinking about creativity was the individual. Academically, the focus was predominantly on psychodynamic, personality, humanistic, and cognitive processes. Fueled in part by the context of the Cold War, considerable emphasis was placed on finding the best and brightest, and the selection of gifted individuals.

The PPP model meant that by definition creativity was a function of an individual. Making the individual – the Person – the unit of analysis lead to an intensive study of the creative person, but it also meant that the study of creative collaborations, groups, and environments was almost entirely excluded. Creativity was conceived to be something that occurred *only* in individual persons. The creative process was considered to be fundamentally intra-psychic.

Social psychologists stress that having an idea is not enough, and that the role of the environment has to be included in order to provide a fuller understanding of the dynamics of creativity. Motivation, a key dimension of creativity, can be inhibited by certain kinds of social environment. The study of the environment therefore became a new and important dimension which found particular resonance in management and organization studies where, in the 1990s, innovation was becoming an increasingly important topic. If the environment in a group, organization, or even a country was not conducive to new ideas, then no new ideas might ever become a reality even with a high number of creative individuals present.

Social psychologists also address the question of the creative product. They point out that calling something a 'creative' product involves a judgment. This judgment has to be made by a person or group of persons, and involves a community of

'gatekeepers,' such as art critics or the editors of scientific journals. It is therefore important to understand who makes those judgments, how, and why.

The 3Ps, Person, Process, and Product represented the Who, How, and What of creativity. Who is or can be creative? How does creativity manifest? What is considered creative? Social Psychology was the first to begin to challenge this tripartite definition systematically from within the dominant discipline studying creativity, psychology. As a more 'social' approach has been introduced into the research, the 'Who' has begun to include groups, collaborations, and social systems. The creative process, the 'How,' is no longer confined to an individual intra-psychic process but may be seen to be emerging in the interactions between two or more individuals, and stretch from the conditions receding the emergence of an idea to the actual performance or creation of the product. Not just writing a song, or play, but performing it, with all the complex factors that involves.

The 'What' of creativity, is, according to Social Psychologists, a decision and judgment made about a product. There is nothing *intrinsically* creative about any product, process, or person. In order to be creative, something has to be deemed to be so by human beings. This perspective, which in sociology dates back at least to labeling theory, had not been explicitly articulated in the context of creativity research. It has been the source some considerable controversy.

Today there are at least 4Ps in the study of creativity, with the 4th P representing 'Press' or the social environment of creativity. Other Ps have been proposed, including Persuasion, which also highlights the importance of the relationship between the creative person, the creative idea, and the environment. As our understanding of the complexity of creativity grows, Social Psychology's key contribution has been to highlight the importance of the 4th P.

Motivation and Environment

Social Psychology has long studied the social influences on motivation. In the context of creativity research, this has also proved to be a valuable entry point. What is the relationship between creativity, motivation, and the environment?

To be motivated, means *to be moved* to do something. Unless we are moved to do something, it is unlikely we will be creative in doing that task. Motivation can therefore be thought of as a person's attitude toward a task, which ranges from being highly motivated and therefore wanting to move towards a task, to being highly unmotivated to do it, and wanting to move away from it, presumably as fast as possible. Research indicates that intrinsic motivation is a key factor in creativity. Intrinsic means 'from within.' Intrinsic motivation literally means that we are moved from within to do something. The intrinsically motivating factors can include fascination for the subject, enjoyment while performing the task, or a feeling of accomplishment. Intrinsically motivated people enjoy what they do, and they do so because they find the task itself rewarding. The journey is the reward.

Extrinsic motivation is motivation that comes from external sources rather than the pleasure of the task itself. Financial incentives and social approval are examples of extrinsic motivation. Extrinsically motivated people do the task because there is an external reward attached to it. The task itself is not what they enjoy; it is the reward (financial or otherwise) that provides the appeal.

There is ample evidence to suggest that people are much more creative when they are intrinsically motivated, rather than when they are driven to perform by extrinsic motivation. This finding makes intuitive sense: performing a task because it provides personal enjoyment or a basic feeling of gratification is a very different type of motivation than doing something because of external pressures or extrinsic rewards, or 'just to make a buck.' Yet, using rewards to manipulate or control behavior, achieving an expected reward, meeting deadlines, winning or competing, or managerial edicts are all frequently used motivators.

A particularly interesting implication of this research of course is that whether a job is intrinsically interesting to us or not is on some level a personal choice. This choice as to how we view a task or job reflects a subjective dimension of work. We can choose to find our particular task boring, or we can find something fascinating about it. Even dishwashing can be interesting if performed with certain states of mind. It is possible to focus not on the nature of the task itself (dishwashing does not strike most people as an intrinsically fascinating task), but on the nature of our awareness while we perform a task. If we are not interested in a task, we tend not to do such a good job. If our interest is in doing a good job, and working at our peak regardless of the nature of the task, we can actually 'be moved' by the task. It is also possible to reframe the task at hand, from one that is desperately boring to one that is potentially exciting – finding a new way of performing the task, or finding something that we can learn while we do the task.

Intrinsic motivation is diminished when external rewards are used to make people perform. The presence of such extrinsic factors alters peoples' perceptions or reasons for engaging in the task. Creativity will be inhibited if the perception is that a task is being performed for the purposes of getting a reward, rather than because of intrinsic interest in the task itself. This does not mean that creativity requires the total absence of rewards or recognition for good work, simply that external reward should not be the main motivation.

Expanding the Creative Process: The Where and How of Creativity

When approached in a wider perspective, the creative process can be seen as a phenomenon that emerges in many different contexts and in different ways. Even in the arts and sciences, historically the privileged contexts for creativity, there are many different ways in which creativity manifests. The novelist at his desk, a scientist in her lab, a jazz band performing together on stage, and a large crew working on a motion picture. Most of the eminent creative individuals studied by psychologists did their work essentially alone. They were scientists, novelists, mathematicians, painters, and poets. Poets, novelists, and painters can do their work almost entirely on their own, if we limit our scope to the production of the actual poem, rather than its distribution and dissemination. But what of the performing arts, where theater or musical groups have to work together to create a performance, or songwriting teams or software development? It is interesting to note that much of the impetus for a more social psychological approach to the study of creativity came because the initial research was not addressing all the dimensions of creative work. In R&D labs or theater productions, collaboration is essential. Many scholarly articles these days are coauthored, which makes writing and research a collaborative process. As innovation has increasingly become a core competence for business in the twenty-first century, there is a need to understand creativity in the context of relationships, organizational structures, and more broadly, a series of environments.

Creativity and Interactions

A subject that is only just beginning to get the interest it deserves is how creativity can be triggered by relationships. There is a long history of creative collaborations, with songwriting teams such as Gershwin and Gershwin, Ellington and Strayhorn, Lennon and McCartney being classic examples. Other important creative relationships include Marie and Pierre Curie, Pablo Picasso and Georges Braque, Margaret Mead and Gregory Bateson, Steve Jobs and Steve Wozniak, Igor Stravinsky and George Balanchine. The nature of these relationships and how they appear to have triggered periods of intensive and extensive productivity is still under-researched. How do certain relationships stimulate greater creativity and productivity?

The performing arts and the nature of creative groups are also under-researched in the United States, although there has been an emerging interest in jazz groups and R&D teams. Creative groups can have very different characteristics. For a jazz band, the process of performance is the product. For R&D teams there is no such immediacy and the nature of performance is different. Whereas for a jazz group the process is the product, for an R&D team the process leads to a product, but they are not one and the same.

It has been argued that one of the barriers to the study of groups has been methodological. The argument from psychologists has been that groups are harder to study than individuals. But it may be that the problem lies in the methodologies generally available to psychologists, because sociologists and even social psychologists have extensive experience studying groups, with a particular focus on qualitative methodologies.

Sociological works such as Howard Becker's (1963) *Outsiders* and Robert Faulkner and Becker's (2009) *Do You Know...?* illustrate how creative groups can be studied.

Groupthink: Eliminating the Creative Process

Research on creativity in groups is a relatively recent phenomenon. Groups were mostly associated with the phenomenon known as groupthink, which is in fact quite antithetical to creativity. An awareness of the phenomenon and its characteristics is important in order to remain alert to how groups can actively block creativity.

Groupthink involves a number of factors. They include:

- the unwillingness to examine anything but a few alternative courses of action, often only two, without a survey of the full alternatives;
- failure to examine the course of action initially preferred by the majority of the members from the standpoint of non-obvious risks and drawbacks that had not been evaluated originally;
- neglect of courses of action initially evaluated as unsatisfactory by the majority;
- little or no time is spent discussing whether nonobvious gains have been overlooked or whether the ways of reducing seemingly prohibitive costs which make alternatives undesirable;
- few if any attempts to obtain information from experts who can supply sound estimates of losses and gains to be expected from alternative courses of action;
- selective bias is shown in the way the group reacts to factual information and relevant judgments from experts, the media, and outside critics;
- members take interest in facts that support their initially preferred policy, and take up time in their meetings to discuss them, but they ignore facts and opinions which do not support their policy; and
- members spend little time deliberating about how the chosen policy might be hindered by bureaucratic inertia, sabotaged by political opponents, or temporarily derailed by the common accidents that befall the best of plans.

Groups that become victims to groupthink have already made up their minds and are unwilling to listen to any other views. There is a pressure to conform, and go along with the group consensus. In terms of the creative process, they cannot accept divergent thinking, because they have already converged on the right policy or plan. Victims of groupthink therefore eliminate creativity altogether to the extent that no new perspectives or alternatives are encouraged. The group process to some extent displays processes that occur at the individual level but writ large. 'Premature closure,' or the unwillingness to explore alternatives after the initial diagnosis, is the most common error in medical diagnoses, for instance.

Environments that Support Creativity

Some social environments promote creativity, whereas others can inhibit it. Traditional management practices and organizational structures were not designed to foster creativity. On the

contrary, the focus was on conformity and predictability. The main metaphor for an organization was the machine. Considerable changes have occurred in the more than 100 years since Frederick Taylor articulated his model of 'scientific management,' but it is telling that it has only been in the last two decades that there has been any sustained research into environments that foster creativity, and creativity in the workplace. The research indicates that the characteristics of creative environments are paradoxical or 'cybernetic' in the sense that they involve navigating between 'creative tensions' such as being too challenging or too boring, specialization and a broad outlook, autonomy and the need for respect and approval, and so on.

If tasks are not challenging enough, they are not likely to elicit intrinsic motivation and creative thinking. On the other hand, too much challenge can result in people feeling overwhelmed and in 'over their heads,' creating a high level of anxiety that inhibits the capacity for creative thought. Mihaly Csikszentmihalyi (1997) has identified the 'flow state,' beyond boredom and anxiety. This is a condition of high performance that is just challenging enough to push the person beyond their comfort zone but not far enough that they are overwhelmed by anxiety. The original research on flow state was with individuals, and recent research has suggested that particularly high-performing groups may also experience a collective flow state.

An important element in enhancing creativity in organizations is to match peoples' interests and skills with the right assignments. A good match requires knowledge about the parties involved and the nature of the assignment. The jazz big-band leader Duke Ellington is said to have made sure he even knew how his musicians played poker. He wanted to know all about them in order to be able to match them with solos in the right songs. That way he could write songs that reflected the musicians' passion and ability and find a fit between individuals and the larger whole.

Creative environments do not stress overspecialization. They allow the freedom to move around in a variety of disciplines and knowledge bases. In fact, many innovative new ideas have come from individuals who are not overspecialized and bring in information or ways of approaching problems from other disciplines or areas of research. Specialization offers a sense of security because one is in familiar territory. Drawing on unfamiliar disciplines means our expertise is reduced, and therefore losing expert status. Comparatively speaking, we become a relative beginner. This is a challenge, both to our status and to the ability to gain familiarity with new material. These challenges keep creative individuals fresh, and environments that allow for this cross-pollination remain stimulating. They require self-confidence and the ability and willingness to keep learning.

Creative individuals tend to be autonomous and nonconforming, but this does not mean they do not care at all what others think of them. They do want to work in an environment in which they are appreciated and respected by their peers. It is a disincentive for them not to know how they are being assessed by their peers, and not having any way of gauging how their own contribution is being received. Knowing that we will not be ignored and our views will be given a serious hearing also helps to build an environment supportive of creativity.

Environments where the fear of failure is high, where failure is strongly penalized inhibit creativity. Fear of failure inhibits risk taking, and with it the likelihood that something new and creative will be uttered, let alone tried out. Environments that support creativity provide 'champions' for creative ideas – whether they come from teams or individuals – that provide external support and advocacy and help them navigate the organizational bureaucracy.

Micro-management is not conducive to creative environments and creative work. Amabile usefully differentiates between tasks that are *algorithmic*, that involve specific, pre-established steps that have to be followed very closely, with one right way and one right answer, do not lead to creativity. On the other hand tasks that are *heuristic*, with a clear expectations and considerable autonomy, have been shown to be much more likely to lead to creativity.

Environments that foster creativity cannot have the old 'look busy' attitude of the assembly line where a minute of distraction can lead to a breakdown. The creative process involves periods of immersion and incubation, of mulling over an idea, where no apparent 'work' may be seen to be going on. Periods of relative isolation, meditation, and reflection are required. Many creative scientists spend time both in the world of theory and the world of application. Along with freedom from external constraints, creative individuals often need the time to be alone with their creative process and not be interrupted. This is not to say that they do not also need time for vigorous exchanges and interactions. The creative process requires both isolation and interaction, and environments that permit both those 'moments' in the process.

Environments that support creativity encourage creative dissent. They allow for vigorous exchanges of ideas, challenging assumptions, and discourage conformity. Creative individuals may not, and often don't fully share the goals and interests of higher management. What sets them apart is that they are open to listening, and will take direction, if they know they are also being listened to and respected for their opinions. At the same time, creative ideas may initially seem bizarre or wrong-headed, so in order to support creativity, it is also important to be able to allow ideas to emerge and not attack them and test them too aggressively before they are fully formed.

Disciplinary and Philosophical Considerations

In the United States, creativity research has historically been the province of psychologists. Within psychology, personality and cognitive psychologists were the most represented, as might be expected given the 'Person' and 'Process' framework. The publication of Teresa Amabile's (1983) *The Social Psychology of Creativity* work was significant because it brought a different (sub-) disciplinary perspective to bear on the topic. While still within the larger discipline of psychology, social psychology's entry into the discourse of creativity marked the beginning of what was to become a stream of more 'social' research, with a focus that extended beyond the individual.

The emergence of a more social approach has raised numerous complex and important issues that can in turn be traced to ongoing debates in the philosophy of social science. It also highlights the role of disciplines in framing questions and entire subject areas.

Broadly speaking, Psychology is the study of the individual person (whether individual personality, cognitive processes, behavior, mind, brain, etc.), and Sociology the study of society. Social Psychology arguably resides between the two, in the sense that it is interested in the relationship between self and others. This includes, for instance, how people relate to one another, how social factors influence our behavior, and how people think about each other.

Social Psychology has made important contributions to our understanding of creativity because it has addressed aspects of creativity that were traditionally either not addressed at all, in the dominant discourse of creativity, or addressed in much less depth. For instance, the selection of eminent creative individuals for the classic research conducted at the *Institute for Personality Assessment and Research* in Berkeley California on the creative personality was done by asking a representative sample of successful architects to nominate those in their field who they considered most creative. This was the accepted method of selection, but the purpose of the selection was to study the eminent individuals. It is only later that this 'social' dimension was problematized and proposed as an indication that creativity should be thought of as a social judgment rather than the function of an individual's personality or mental process.

Controversy

Along with the contribution of new, more social, perspectives there has also been considerable debate and controversy. One of the central sources of controversy has been the emphasis of some of the more socially oriented researchers to stress the role of judgment and attribution. The central idea is that in order for an idea or product to be creative, somebody has to say it's creative. Without the label 'creative,' it is by definition not creative. Judgments about creativity in the arts and sciences are usually made by a small group of gatekeepers, art critics, journal editors, and so on. In some models of creativity, the environment now seems to play a more significant role than the individual. Creativity appears to be a function of judgment. This shifts the attention to the group making the judgment, and to the larger social environment. As the focus shifts towards the creative person's interactions with his or her environment, it also begins to address issues of how individuals involved in creative work can manage their image and engage in impression management to become more successful. It takes attention away from what was traditionally studied, the individual and her or his process.

Some psychologists have argued strongly that research on the social dimensions of creativity is valuable but not essential, since such factors as reputation and judgment actually hinder our understanding of the phenomenon of creativity *itself* inasmuch as they are *about* creativity. The social dimension involves subjective judgments made by people about creativity, something quite different from the creative process itself. This debate about judgments about creativity interferes with the actual study of the creative process.

Some representatives of sociological approaches to creativity have sometimes harshly dismissed earlier forms of creativity research, particularly personality approaches, suggesting that this research can now safely be discarded in favor of the more social approach. Any characteristics imputed to creative

individuals can only occur and be relevant in a particular context. To speak of universal characteristics of the creative person is simply not possible. This is in many ways a rehash of the critique of personality theory made in 1968 by Walter Mischel. Nevertheless, the research on personality and on the creative person has continued, and, with some modifications, the latter generally continues to be viewed as a major contribution to the understanding of creativity.

The controversy about the introduction of a more social element in creativity research has many ramifications, including disciplinary allegiance. Eminent psychologists who have introduced more social dimensions in their research have made a point of explicitly affirming their loyalty to psychology. They are not 'switching sides,' they point out, merely broadening the frame of creativity research. The fact that these kinds of statements need to be made reflects the tension that exists between disciplines, disciplinary affiliations, and the problems that can be associated with stepping out into other disciplines.

Philosophical Assumptions

Another reason these controversies have arisen is because different underlying philosophical assumptions lead to very different perspectives on the subject. In very broad terms, one key difference between psychology and sociology is the *unit of analysis*. Psychology views creativity as the result of characteristics, processes and properties of individuals. Social Psychology has studied how the external environment affects the individual's motivation and creative performance. Sociology views creativity more as a function of social structures and processes. In the philosophy of social science, these different perspectives are sometimes referred to as atomism and holism, or methodological individualism and methodological holism respectively (Simonton, 1999).

For methodological individualists in creativity research, the focus is on the individual and whatever is outside the individual is essentially *epiphenomenal*. It is not necessary to include these factors in order to gain a full understanding of the subject. Even in the context of a seemingly solitary activity as writing, Burke Lefevre summarizes the critique of methodological individualism by emphasizing the impossibility of being completely separated from one's social environment and criticizing

(T)he inadequacy of a conception prevalent in current composition theory that invention is the act of an atomistic individual who recollects or uncovers ideas from within, all the while remaining apart from a material and social world. (Burke Lefevre, 1987, p. 8)

For methodological holists it is the individual who is largely epiphenomenal. Specific individuals are merely vehicles for ideas that were part of the *zeitgeist*, or 'in the air' [see *Zeitgeist*] The implications are considerable. Since methodological individualism has been the dominant approach in American creativity research, it is not surprising therefore that creative collaboration, group creativity, the study of creative cities and epochs and generally of environments that foster or hinder creativity have received less attention, with some notable exceptions.

If psychologists have focused on the individual, social psychologists have brought discussions of the social environment into the creativity discourse. Disciplinary perspectives often

emerge in opposition to each other, and this can be seen in the individualist and holist approaches to creativity. The individualist approach has been dominant since the 1950s, and it is now becoming clear that in order to address specific phenomena such as group and collaborative creativity, and to reflect findings in the natural and social sciences about complexity, interconnectedness, and interdependence, a more social approach is emerging. It is not clear whether this more social approach will succeed in integrating the findings of the more individualist, person-oriented researchers, or whether the individualist approaches will be renewed by the challenge of alternative views. Certain proponents of the Systems Approach propose that in order to address this problem it is necessary to go beyond a certain way of thinking that is reductive and disjunctive, reducing creativity either to a social or an individual phenomenon, and adopt a way of thinking grounded in systems and complexity theories.

The underlying philosophical assumptions of the two major perspectives on creativity have further differences. It has been argued that the psychological individualistic approach is fundamentally *idealistic* in the sense that the focus is largely on the generation of creative ideas, but no systematic attention is paid to how those ideas can become a reality. Idealist philosophy is more interested in the idea rather than its physical manifestation. An idealist aesthetics holds that the score of a musical composition is an ideal which can only be approximated by a performance because it is closer to what the composer had in mind, and subject to less translation and interpretation. Unlike the psychologists, who focus on the idea, sociologists have brought a different perspective to the table, namely a more materialist philosophy. Particularly with sociologists of work we see this in their close study of what it actually means to work in professions such as the arts and put on a jazz performance, get a motion picture into the theaters, in a novel into bookstores, and so on. The romantic mythology of the creator as lone genius takes a back seat to the network of relationships necessary to take any creative idea into the world.

The credits of a motion picture begin to give some idea of the enormous collective effort that is required to bring a movie in front of the public. The same is true for a musical recording, a book, and even a school production of a musical requires extensive collaboration. To attribute the creation of a motion picture or the performance of a jazz group to one individual is very problematic.

The sociological approach has broadened the understanding of creativity to the extent that it tells us about how an idea becomes a reality, and clearly this is an extremely important dimension of the process. A greater understanding of how creative ideas become realities can assist in the creation of systems that support creativity more. Nevertheless, the question remains, where do we draw the boundary around what constitutes 'the creative process?' Is the creative process confined to the generation of the idea, or does it extend to include the entire production of a movie, including the script writing, editing, and all the support functions from the technical to the logistical?

Individual and Society

The influence of Postmodern and Feminist perspectives on psychology and on its underlying philosophical assumptions

is gradually being felt. This involves, among other things, a shift away from the emphasis on individual mind and an objectively knowable world towards a more communal, socially constructed understanding of the self and of knowledge. Such an approach does not make such hard and fast distinctions between self and society. Rather than focusing on two separate entities, the stress is on relationships and on both self and knowledge as 'constructed,' rather than given. The self emerges out of a network of relationships and does not have an 'essence.' The self changes in various contexts so one cannot speak of universal traits or more generally of 'the' 'creative person.' 'Essentialism,' the proposition that individuals have an unchanging essence, is being challenged by views that are more contextual and argue for the social construction of the self.

If one social psychological approach asks to what extent the social environment hinders or fosters creativity in an individual, another more radical way of looking at the issue is to suggest that there can be no clean split between individual and society. No individual creator can function as a human being, let alone as a successful creator, without being part of a discourse, a larger tradition. The relationship between the individual and the social environment cannot simply be reduced to the way the social environment supports or hinders the creative person. It is a more complex matter, because society is already 'in' the person (language, education, culture, scientific or artistic heritage and practices, etc.) just as the person is 'in' society. The focus on relationships and interactions in the creative process has raised questions about the nature of the person. The individualist, closed-system view of Piaget and others is critiqued and contrasted with more relational, 'socially constructed' views of the individual, which often draws on the work of the Russian psychologist Vygotsky. Vygotsky's approach was sociocultural, and stressed the central role of social interaction in cognition.

These are the sorts of philosophical problems that are being raised by the 'social constructionist' strain of social psychological research, questions that veer far into the philosophical and theoretical domain, but whose implications are considerable for our understanding of creativity, which historically dates back to Romantic conceptions of *ex nihilo* creation and genius without learning. While these Romantic 'myths' of creativity may seem remote and unlikely in the twenty-first century, they do persist to some extent in the public imagination. As an example, it is only in the first decade of this century that several popular books about the importance of hard work for successful creatives have been published and begun to make an impact in the popular culture, countering the Romantic myth of 'genius without learning.' Likewise, the research on group creativity is still minimal compared to the research on the creative person or the relationship between creativity and mental illness, for instance, an association that is closely connected with Romanticism.

Women and Creativity

Much if not most of the creativity research has been about eminent individuals in the West who are white males. The picture that has been built up about creativity, the creative person, and the creative process is based on a sample that is predominantly white and male. In the last 50 years tremendous

changes have seen many more women become prominent in the arts and the sciences. Women were historically not given access to the domains where creativity was traditionally recognized, namely the arts and the sciences. In Europe and the US women were not allowed to practice drawing nudes, give concerts in public, go to medical school, and study science until the middle of the nineteenth century. But does that mean that women were not being creative in Europe and the United States until the middle of nineteenth century? Or merely that the socially constructed definition of the who, where, and how of creativity was preventing us from understanding how the creativity of women was manifested? The recent concept of everyday creativity offers us an interesting new possibility – both because it is itself a new 'constructed' understanding of creativity, and because it allows us to see creativity in places and activities where before it would not have been looked for. The title of Virginia Woolf's *A Room of One's Own* is illustrative because it shows that women had trouble finding the time and the place to be alone. Women's creativity throughout is described as being more relational and therefore 'social' because it manifested in the context of the family and everyday life.

Future Trends

In a networked society, it is not surprising that research shows college students identify creativity more with everyday events and social relations rather than with extraordinary individual achievement in the arts and sciences. This points to a changing concept of creativity in the 'implicit theories' of new generations' one that may reflect the more 'social' approach. The challenge for both social and research views of creativity is to incorporate the best of all the research that has gone before, and to develop a new, richer, and more inclusive understanding of creativity.

Conclusion

The Social Psychological perspective has opened up a considerable opportunity for debate, expansion, and integration in the research on creativity. A more 'social' perspective goes beyond the disciplinary boundaries of creativity, veering into sociology but eventually pointing the way to a new inter- or trans-disciplinary approach that draws on a plurality of disciplines.

Glossary

Adaptation In evolutionary science, a structure, physiological or psychological process, or behavior that enables an organism to survive and reproduce. As well: the evolutionary process leading to such traits' formation.

Darwinism The theory of evolution by natural selection, proposed by Charles Darwin (1809–1882).

Epigenetic rule Genetically shaped procedures of brain development that direct the assembly of mind during enculturation; instantiated as the timing and logic of the activation and repression of the nervous system's developmental genes.

Evolutionary psychology The study of behavior and mentation – in humans and animals – as Darwinian adaptations.

Fitness As used in evolutionary science, differential representation in later generations.

Gene–culture coevolution The coupled evolution of genes and culture, that is, of genes and the artifacts, behaviors, and belief systems transmitted by learning among members of a society, and the multilevel holistic patterns they form. Learning one culture in all is uniqueness, depth, and particularity is called enculturation.

Group selection Change in gene frequencies caused by the differential survival and proliferation of groups of individuals within a population.

Kin selection Change in gene frequencies caused by individuals favoring or disfavoring the survival and reproduction of relatives (others than their own offspring) who possess the same genes by common descent. Kin selection is expressed during evolution through inclusive fitness, the sum of an individual's own fitness plus all its influence on fitness in its relatives other than its direct descendants.

Natural selection The differential contribution – through survival and reproduction – to subsequent generations by individuals of different genotypes but belonging to the same population. When natural selection acts simultaneously across diverse scales on the same population, from individual gene and organism through kin group to social alliance and other subgroups and subpopulations of various sizes right up to the population as an adapting whole, it is called multilevel selection.

Reciprocal altruism The benefits to survival and reproduction gained through alliances with non-kin, in which adaptive aid expended on others is likely to be reciprocated at some future date.

Sociobiology The evolutionary science of social behavior in all its conceivable forms, stressing especially the properties of entire societies. As relevant to sociobiology, a society is a group of individuals in the same species organized in a cooperative manner.

Introduction

Sociobiology is the evolutionary science of social existence. As a scientific discipline its goal is to understand all patterns of social living, including those of humans, from the perspective of evolutionary biology. The principal technical novelty of sociobiology is its treatment of societies as populations subject to evolution by natural selection. Each animal society has a characteristic size, networks of gene flow, means of communication among its members, dominance structure, and other traits of the population considered as an intact whole. These traits can be observed as they change over time, just as the chemistry, neurobiology, and behavior of the society's constituent organisms can themselves be studied. The principal intellectual novelty of sociobiology is its hypothesis that such whole-society traits are emergent, adaptive outcomes of Darwinian evolution. Thus sociobiology is, in a direct sense, the cosmology of the sciences devoted to sociality. It examines social existence in the broadest possible scientific perspective, erecting comparative frameworks that accommodate all conceivable patterns of group living from the simplest communal microorganisms to the most passionately conscious creative primates. In principle it also embraces, for the purposes of teaching or deductive clarification, the systematic description

and comparative analysis of social forms thus far only conjectural or hypothetical, such as sapient communal insects or replicating creative machines.

Origins

Sociobiology is the brainchild of Edward O. Wilson, Harvard University's fabulously gifted ant specialist and natural philosopher. A succession of books by Wilson defines the canonical form and content of this young science. His masterful 1975 *Sociobiology: the New Synthesis* forged diverse, widely scattered ideas and facts about social evolution into a system of unprecedented explanatory scope. The glittering insights marshaled by Wilson especially included William Hamilton's concepts of kin selection and inclusive fitness beyond the individual genetic success; Robert Trivers' influential notion of reciprocal altruism as the evolutionary cement bonding alliances among genetically unrelated members of the society; John Maynard Smith's vision of social behavior as games played out with Darwinian strategies of conflict and cooperation among relatives and nonrelatives alike; and the subtle effects of group selection, the once-taboo notion nurtured by Wilson and others that natural

selection can act on multiple levels of intact groups as units of survival and reproduction within the society, not just on single genes or individual organisms.

Whereas *Sociobiology* devoted most of its pages to animal social existence, Wilson's *On Human Nature* – his Pulitzer Prize winning book published in 1978 – flashed the new science's intense beam into the depths of human behavior and sociality. A few years later, Wilson and I (in the 1981 *Genes, Mind and Culture* and the 1983 *Promethean Fire*) introduced gene–culture coevolution as sociobiology's key to mind and culture, humanity's symbolic worlds. In his 1998 *Consilience*, Wilson turned that key on behalf of universal scholarship, arguing powerfully that a sociobiological approach to mind and culture opens the path to essential unification not only among the sciences of humankind, but within and between the sciences and the humanities themselves.

The attempts by Wilson and others to establish human sociobiology triggered intense debate about the proper role of science – especially evolutionary science – in human affairs and in the so-called human sciences of the time. Those academic fights, sometimes recalled as the sociobiology wars, are now a case study in intellectual politics and idea succession in science. Today the idea that genes guide the brain's development, along the way shaping mind, behavior, and social living, is less controversial thanks to the Human Genome Project and several decades of nonstop progress in the brain and behavioral sciences. Scholarly attention in sociobiology now focuses on hypothesis formulation and testing, and less on general arguments about feasibility or intellectual legitimacy. Contemporary sociobiology is thus a vigorous young science sustained by specialist journals, college courses, learned societies, and popular books – a field driven by several generations of investigators siloed across the problems of social living revealed in hugely diverse zoological taxa. Alongside these primary investigations, intellectual historians, philosophers, and social critics continue to map the field's past, present, and practical import.

Close Associates

Sociobiology does not stand alone among the evolutionary sciences in its focus on social behavior. Sociobiology is closely allied with ethology and evolutionary psychology, fields which can be characterized briefly as the evolutionary study of behavior in individual organisms under natural conditions. All three disciplines deal with the history of species and the way behavior adapts organisms to their environment, serving the needs of survival and reproduction. Ethology and evolutionary psychology concentrate on the details of individual behavior, including the role of brain activity and its development over the individual's life history. Sociobiology deals more with the organization of entire societies, and with how these patterns of social organization emerge from individual behaviors stressing cooperation and conflict. Although rooted in the behavior of the individual members of the population, such patterns are difficult or impossible to predict solely on the basis of information about individuals alone, and require approaches that consider the feedforward and feedback among multiple organizational levels.

Pinnacles and Paradoxes

Sociobiology identifies four great pinnacles of group cohesion across the range of evolutionary possibilities in the patterns of social living: the colonial invertebrates (corals, sponges, colonial jellyfish); the social insects (ants, bees, wasps, termites); monkeys, apes, and social mammals excluding human beings; and humankind. Against the vista afforded by these pinnacles are set two seeming paradoxes: first, that sociality exists at all, and second that as we traverse the four pinnacles in order of increasing behavioral complexity we seem to slip progressively downward in the population's social cohesion, rather than ever upward.

The members of advanced colonial invertebrates, such as the Portuguese man-of-war, show extreme task specialization and are fitted together into a single superorganism almost indistinguishable from a single well-knit multicellular organism. The insect society is far less well integrated than that of a colonial invertebrate, but is still more so than vertebrate and human societies. The individual worker insect may show distinct phenotypic and behavioral specialization related to its tasks and duties in the colony. Although far from perfectly coupled to and integrated with those of its nest mates, the behaviors issued by its comparatively modest nervous system tend to be altruistically directed to the welfare of the colony as a whole. Such holistic patterns of response also qualify social insect colonies as superorganisms, albeit less perfectly integrated than the colonial invertebrates. Vertebrates have big, flexible brains compared to social insects, and complex flexible behaviors; but their societies depart even further from an idealized pattern of total societal harmony. The individual vertebrate only marginally serves the welfare of its group. In comparison with coral polyps or ant workers, the members of a vertebrate society are self-centered, strife-ridden, and preoccupied with sexual opportunities.

Then, remarkably, this skid toward lower societal integration halts and reverses in human societies. Possessed of a brain supporting fully symbolic language, imaginative consciousness, generalized long-term memory capacities, and long-term contracts upon which elaborate forms of reciprocity can be based, we humans apparently have bucked the paradox and attained relatively high levels of cooperation, altruism, division of labor, and social integration – all without surrendering our basic mammalian heritage of personal identity and individual welfare.

What is going on?

Natural Selection and Selfish Genes

In seeking to unlock such puzzles, sociobiology centers on 'why' questions: why social behavior exists; why certain patterns of group cohesion define a population; or why a species' mating patterns have a certain specific form. The scientific 'why' can be answered only through the study of history and, at all levels from molecular through to ecological, the history of biological systems is by the definition of evolution. Its creative process is natural selection acting through, and on, genetic variation, resulting in the differential transmission across generations of genes that affect survival and reproduction.

Natural selection does not act alone. Mutations can occur at such high frequency as to change the percentage of mutants in a population without the involvement of natural selection. As well, immigrants can bring new genes into the population at a high enough rate to change its overall genetic composition. If the population is a small one, random sampling effects caused by mating choices and genetic recombination can shuffle genes in an unpredictable fashion from generation to generation. Sociobiology hypothesizes that, taken over long periods of time relevant to biological evolution, these intriguing processes are less potent than natural selection in shaping behavioral adaptations and the integrative structure of social populations.

Individuals of course do not duplicate themselves during the process of reproduction. They transcribe their genes and impart them into their progeny. From the viewpoint of evolutionary theory, and hence sociobiology, all the traits of individuals and societies are therefore potential enabling devices for the expansive replication of hereditary material involved in the expression of these traits. Consciousness, language, moral sensibility, loving tenderness toward children, creativity – all are possible adaptations by which genes might spread through future generations.

And hence the first paradox: Why sociality at all? Why not every individual for itself as the Darwinian universal? If it pays genes only to be selfish, in other words to encode adaptations that promote their particular individual survival and replication, why should their behavioral effects tilt toward cooperation and help? Cooperation entails actions that aid others at the cost of one's own time and effort. It is the essence of social life but seems to steal time and effort that might go into making copies of one's DNA. How is such altruism and sociality possible in a world of selfish genes?

Genetic Selfishness Begets Altruism

We know that parents may sacrifice much on behalf of their children, sometimes even their own lives. Among humans as in other species, so long as offspring are preserved the parents' genes are not lost. They are passed on, and this gives us the key to the first paradox. If the self-sacrificing behavior of the parent is influenced by some of the favored genes (via neural hardwiring or the directed learning of nurturance, for example), then that particular form of altruism can spread through the population. Altruism of a broader kind can evolve by essentially the same mechanism: full siblings share, on average, half their genes through common descent, so if an individual makes a sacrifice on behalf of a brother or sister – and in consequence the sibling has more children – the altruistic act can cause an increase in the number of genes in the population that are identical to its own. This form of natural selection is called kin selection and was enunciated by the British evolutionary theorist William Hamilton during the mid-1960s. Its Darwinian force, inclusive fitness, can result in the spread of sociality among close kin other than offspring.

Beyond first cousins, however, it takes a relatively great increase in the reproductive success of the benefited relative to compensate one's unilateral sacrifice. So kin-selection altruism toward distant relatives is expected to be rare. In organisms with potent capacities for situation-specific memory and

problem solving, such as humans and the most intelligent monkeys and apes, cooperation and sociality is generalized as reciprocal altruism, a Darwinian mechanism set forth by the American evolutionary theorist Robert Trivers early in the 1970s. In this form of giving and self sacrifice, the altruistic act is performed among individuals whose genes incline them to repay in kind, perhaps at some future date. Among such organisms, adaptations for complex strategies of reciprocal altruism, set in patterns of transient, ever-shifting alliances and confrontations between group members, can spread through the population by natural selection. The enhancement of survival and reproduction by reciprocating patterns of do-and-repay has been proposed as a main force shaping the evolution of primate cognition and emotion, including the detection/recording of (and, conversely, the capacity for and response to) deception and cheating.

Refracted through the powerful conceptions of reciprocal altruism, kin selection, and group adaptation, answers to sociobiology's second paradox also snap into focus. The members of coral colonies and other similar tightly clustered groups of invertebrates originate from a single fertilized egg and multiply by simple fission and budding off of entire new organisms. The coresident individuals are genetic clones. Under this circumstance kin selection can easily overcome strictly individual selection: looking after a neighbor is the same as looking after oneself as far as replicating genes are concerned. The calculus of close kinship holds too for the social insects, but with less rigid consequences than for the colonial invertebrates. Colonies of ants, bees, and wasps are comprised mostly of sisters. Because of the haplodiploid mechanism of sex determination in these insects, sisters are more closely related to each other than are mothers to daughters (termites are another story). On the average, three-quarters of their genes, instead of half, are identical by common descent. Thus the insect society is far less well integrated than that of a colonial invertebrate, but is still more so than vertebrate and human societies. In vertebrate social populations, the diploid inheritance governing gene transmission focuses kin selection on near relatives at most, but advanced memory and decision capabilities set the stage for complex cohesive patterns of shifting alliances favored by reciprocal altruism. Hence a vertebrate norm: social life is exploited for the improvement of survival and reproduction of self and immediate kin, along with one's allies-of-the-moment.

Elegant and far-reaching, gene-transmission arguments like these answer questions about why specific patterns of social behavior evolve. Demographic and ecological factors are now recognized as key additional causal elements. These shape, for example, the risks of leaving home to found one's own nest as compared to staying with the established enclave and rearing kin there – in short, of a solitary existence versus the boons of sociality. Modern sociobiological research treats multifactorial hypotheses, in which survival and reproductive success interact with ecology, life history, information transmission, and other causal elements within the evolving population. One such striking instance sits atop sociobiology's fourth pinnacle, where humans have reversed the socially corrosive effects of mental flexibility and used their minds to regain high levels of cooperation, altruism, division of labor, and social integration, all without erasing personal identity and individual liberty.

In order to understand this striking reversal, it has been necessary first to understand how culture and its evolution have refashioned the sociobiological agenda of replicating genes.

Gene–Culture Coevolution

Most animal evolution arises from the differential replication of genetic information, but human evolution obligatorily involves the differential transmission of both genetic and cultural information across generations. Changes in the popularity of a song or an art style over time exemplify cultural evolution in its simplest conceivable form. A hallmark universal to our species, cultures are essential to human existence yet wondrously diverse, organized through species-characteristic central tendencies around which cultural diversity plays. Thus, while human cultures differ hugely in the details of their kinship terminologies, no human culture lacks terms for making sense of one's place as, inevitably, each new generation rises up and the old fades away.

Sociobiology is part of an emerging consensus among the human sciences – in which subjects as diverse as evolutionary psychology, anthropology, developmental neuroscience, and the cognitive and behavioral sciences also play essential roles – that genes and culture do not remain isolated one from the other as they evolve. The neurobiology of human mental development binds them. In this mode of evolutionary change, genes have a voice in determining how a culture's information store affects the growth of individual memory, personality, and character in that society. In 1981, Wilson and I suggested that the term gene–culture coevolution be used to describe the effects of Darwinian natural selection and its key allied population forces on genes, mind, and culture. In gene–culture coevolution a circuit of reciprocity operates. Culture is generated and shaped by the biological imperatives embodied in adaptive outcomes, while genes shaping the complex agendas of learning and mental development shift in response to changing cultural opportunities.

Natural selection figures prominently in the study of gene–culture coevolution, as it does in the kin selection and reciprocal altruism of animal sociobiology. But when culture acts too, natural selection can take paths different from those foreseen on the basis of genetic evolution alone. The diversity of possible evolutionary outcomes can increase, and the speeds with which they are approached change. Cooperative sociality may spread through a gene–culture population without the aid of kin selection, reciprocal altruism, or any of the mechanisms traditionally envisaged to account for animal social behavior. These and diverse other striking possibilities have made gene–culture coevolution an active subject in sociobiology, evolutionary psychology, and the social sciences. Using sociometric data and mathematical techniques, powerful computer methods assay the gene–culture connection through its linkages to behavior governing reproduction, gene flow, learning, and other adaptive forces.

Underlying such behavioral adaptations is individual development and learning. Epigenesis is a term used by developmental biologists to refer to the total process of interaction between genes and environment (including culture) during the course of organismic development, including the development

of the nervous system and the mind. If neural and mental development are approached as complex sequences of temporally organized events occurring at various sites throughout the nervous system, the basic building blocks of these sequences can be identified and described. Wilson and I have suggested that Darwinian forces have organized these basic elements into two principal classes: primary epigenetic rules, through which genes mediate the development of neural networks and information processing from initial sensory filtering to perception, and secondary epigenetic rules, through which the patterned timing and activity of genes mediates the development of cognition, temperament, and personality. The primary rules are the more genetically restricted and inflexible of the two classes; cases involving vision, hearing, taste, and smell have been identified. Each class exerts important effects on the mind's capacity for self-organization, including creativity and innovation.

The organization of sequences and stages in mental development, and the molecular neurobiology in which they are grounded, command interest from developmental psychologists and neuroscientists. They have striking immediate impact on sociobiology too, because their conceivable range of action at once illuminates the principal distinct extremes of gene–culture coevolution (GCC) in the population as a whole.

GCC Via Pure Genetic Transmission

In this mode of GCC, the outcome of brain and mind development is very tightly specified by gene activity; culture and social environment either have no effect, or always lead to the same outcome across the population. The genes determine all. For a human example, consider color. Although the number and semantics of basic color terms is exquisitely culture-dependent, normal socialization has no effect on the number (3) of color receptor types in the retina and their spectral response properties, around which this cultural richness plays.

GCC Via Pure Cultural transmission

In this mode of GCC, gene activity creates another very specific kind of nerve circuit architecture in the brain: one able to learn almost any culture. Thus innate genetic activity during pure cultural transmission does not filter cultural information the way pure genetic transmission of culture does. Indeed the opposite is the case. GCC via pure cultural transmission selects for genes that enforce a huge range of possible outcomes in temperament, personality, emotional valence, knowledge, and morality. The culture and social environment determine which outcomes are realized by these generalized learning capacities. Individuals like this are the blank slates or *tabula rasa* minds popular among social revolutionists and political dystopians of the last century. Not free to shape themselves, *tabula rasa* minds are determined by the forest of cultural symbols into which they are born. Thus under pure cultural transmission the unique properties of individual minds, together with the differences among individual minds, arise solely from differences in their sociocultural environment. Culture determines all. So, for example, in seeking to understand why in my native land of Canada we drive on the right side of the road while our

cultural forebears in England eschew the right side for the left, we do not look to genetic differences between Canadian and British populations. Instead we read deeply into their social histories.

GCC Via Gene–Culture Transmission

The intermediate mode of GCC stretches from the extreme of pure genetic transmission on one side to pure cultural transmission on the other. Gene action during neural and mental development plays a colorful role here. Unlike pure genetic transmission, gene action does not commit the developing mind and brain the one innately programmed specification of which cultural information will be accepted. And in stark contrast to pure cultural transmission, gene action does not flatten the individual's learning potential into a landscape of outcomes determined solely by culture. In gene–culture transmission, the activity of developmental genes establishes hills and valleys of learning preference. The hills mark outcomes partially blocked or less likely to occur; allied cultural information has little or no effect on learning and mental development and is less likely to be transmitted or utilized in an arbitrary manner. The valleys mark outcomes to which the mind's development is more likely to flow. Allied cultural information is strongly preferred and likely to be transmitted within and across generations of the evolving population, and used for specific goals in mental development. Thus, all cultures enjoy rich structures of myth and folklore within the creative uniqueness of each language community; grounding these language arts, however, are the deep universals of human linguistic cognition, a species universal that opens the door to mutual intelligibility and the swiftly meaningful translation of texts between cultures.

In gene–culture transmission, genes act to endow culture learning with directionality, not to program final behavior or mental state or leave the individual open to arbitrary cultural determination. The directionality essential to this form of learning can be operationalized only through choice, by selecting certain outcomes over others, and in humanlike species choice ultimately involves conscious reflective decision. Thus in marked contrast to pure genetic transmission and pure cultural transmission, Darwinian natural selection acting through gene–culture transmission is expected to select for individual minds which, in their creative actions of learning and deliberation, shape themselves. Their epigenetic rules endow them with basic competence for deliberative choice. Thinking to this extent for themselves, they are neither genetic robots nor culture slaves. We therefore begin to see why the hypotheses and proposals of human sociobiology have been found relevant beyond the natural and social sciences, especially in the debates of humanists, philosophers, lawmakers, and theologians.

These are principal conceptual alternatives in the mechanisms of cultural transmission during gene–culture coevolution. Although research is ongoing, provisional inferences may be made on the basis of the advances achieved by investigators in multiple fields across the biological, behavioral, and social sciences including sociobiology. Seen against the background of such advances, the paradigm of the *tabula rasa* or blank slate – ordaining pure cultural transmission – cuts a very poor figure.

Consistently across the developmental events spotlighted by the primary epigenetic rules are signs of either pure genetic transmission, or of gene–culture transmission focused tightly on a narrow range of sensoriperceptual competences. In the development of higher order capacities for learning, choice, decision, and creativity the gene–culture transmission strategies prevail, in which a range of outcomes is notably favored over others. The mode I have here called pure cultural transmission of course remains essential to complete understanding (you may drive on the left while I adhere to the right). However, no evidence supports the hypothesis that pure cultural transmission and the *tabula rasa* strategy of learning alone is suffice to understand human evolution and its consequences for sociality, culture, and creativity.

Kinds of Creative Mind

Sociobiology, through its alliance with evolutionary psychology and neuroscience, has been articulate about the kinds of mind pegged to each of its four pinnacles. The colonial invertebrate mind (to the extent the term mind applies at all) is at most a physiological or homeostatic regulator, dedicated to managing the relatively straightforward nutritive and reproductive requirements of these colonial superorganisms. The form of mind sustained by the social insects' minute but exquisitely organized brains is essentially a reactive automatahood, from which emerges the collective behavior of the insect colony superorganism in the form of the amassed individual actions of the colony members. Such an insect mind is specialized to recognize and support group needs through individual behavioral acts. These in turn are triggered by cues each colony member obtains from its immediate, local environment and the impact of the colony superorganism on that environment. Individual creativity and innovation play no role. Although individual capacities for signal detection and response support an innately limited set of behaviors, the colony superorganism emerging from these simple behaviors has an impressive capacity to assure colony founding, growth, and reproductive release even when the environment changes unexpectedly. Colonial invertebrates and insect societies may not be massively creative agents or innovation generating machines, but within limits can assimilate and adapt to novelty and turn it to Darwinian advantage.

Political is perhaps the word best suited to describe the form of mind sustained by the complex nervous systems of mammals and other social vertebrates: awareness innately tuned to the nuances of shifting opportunities for enhanced survival and reproduction, and capable of the swift decision-making serving the needs of self, kin, and allies. Within the modestly complex proto-cultures sustained by social vertebrates, chance favors those prepared to detect the behavioral innovations of others and funnel them into family and alliance networks. In these settings an unintentional shift in a call form that arouses mate attention, or the sudden appearance of a better termite fishing tool, can spread rapidly among eager adoptees. Innovations matter, and circumspect creators may for a time prosper from the relative advantages they and their allies enjoy. But this is casual creativity, in the sense that group life would continue in its opportunistically Darwinian manner

as smoothly in the absence of the occasional innovation as in its presence, however transiently delightful. And there is a splendid diversity of animal societies to be assessed in this manner. Wilson and I tallied almost 12000 species in which observational learning may circulate information through the population, and thus in which novel information can be seized for adaptive payoff.

The situation for humankind differs considerably from the patterns of creativity and innovation I have sketched above for the other three zoological pinnacles of sociobiology. Unlike the colonial superorganisms and the insect societies, we humans make novelty as well as consume it, to our individual and collective advantage. And unlike the social vertebrates, we have no more than Hobson's choice in the matter. Over its course of several million years, reaching from our early hominid ancestors to now, the reciprocating whirl of gene-culture coevolution has propelled humanity into a postmodern industrial condition in which creativity is not optional. It is essential to our survival. Our planet now teems with fellow humans at the same time its environment deteriorates, stressed by changes born of our species' prior creations and innovations. Our species now must create and innovate to ameliorate (dare we hope erase?) these threats from our past creative efforts – and do so at increasing pace to heal ecologies and feed everyone as our populations and consumption rates grow – or face oblivion. Innovate, or die.

It was not always so. Our hominid ancestors long roamed a planet populated just sparsely with competing conspecifics. During these long ages a planet replete with territories clean and unexploited awaited the roving bands. A modest kit of stone tools and other implements sufficed to gather, hunt, and no doubt try a bit of growing. For a long time creativity and innovation must have been comfortably optional luxuries for the hominid lineages. In the manner of the other social vertebrates with whom they shared the wide horizons, a new tool or vocalization might be welcomed for the burst of transient advantage the innovation gained till everyone had it. But in a world ready with foodstuffs and clean water, life could go on very nicely between times. As population densities edged up, the neighbors crowded in and fresh horizons slowly vanished, along with the low hanging fruit and the clean water. Sometime in this period our species seems to have crossed an evolutionary threshold. Evidenced by remarkable increases in the diversity, refinement, and capability of the tools, by the societal sizes and by complexities signaled in other archaeological remains, there was a creative explosion (John Pfeiffer's term) starting sometime in the Upper Paleolithic 25 000–35 000 years ago. For us humans it marked the transition from intermittent to increasingly rapid cycles of creativity, discovery, and innovation. As I noted above, we are now far enough down this long march of history that our dependence on the ever-quickening cycles is complete. The cycles in turn are propelled by the obligate creator, a form of mind for which we have no evidence prior to our species' creative explosion, but whose actions shape more and more of our planetary culture and its evolutionary future.

The Obligate Creators

Societies hungry for innovation are niches of unquestioned opportunity for those equipped, by way of their genetic and

cultural heritage, to bring forth abundant novelty. As other entries in this Encyclopedia make clear, the psychological equipment behind creativity is the target of vigorous ongoing research worldwide. It takes no great act of intellectual synthesis to dip into this impressive body of investigation and affirm that, among other abilities, creativity (simplistically, the inclination to produce novelty that matters) draws on the gifts of intelligence, domain knowledge and skill, curiosity, adroitness with interpersonal affairs (one's connections), a knack for persistence, and opportunity. These talents are likely to be among those at work in other species, in the innovators we find from time to time in vertebrate and early hominid societies. All are compatible with innovation as an occasional event, and may serve to diversify other behaviors as well besides creativity and innovation. They are part of a possible grand pattern of adaptations and pre-adaptations remaining to be mapped as the bridge between creative behaviors in the social animals, and those in our hominid ancestors and ourselves.

One gift, however, appears to be a hallmark signature peculiar – for better or for worse – to humankind. For the purposes of this encyclopedia entry I will call the resulting phenotype the obligate creator. Obligate creators occur, to the best of my knowledge, only in the human species considered among life on Earth. The obligate creator's origins are, for the time being, shrouded in human history and evolutionary time; similarly, the precise linkages of the obligate creator mind to the developmental action of genetic and cultural information remains largely to be clarified in future research. The obligate creator's traits are definitive however, and in societies dependent on innovation often startling in their effects. Compared to their more easygoing innovator counterparts among the social vertebrates and ancestral hominids, obligate creators are non-stop sources of significant novelty. To ally and foe alike, they seem impelled to create in their favored domain of human affairs. Setbacks do not dissuade them. So intense is their energy and so prodigal their capacities only death or its equal finally stills them. Working sometimes more in isolation and sometimes more as focal points of social networks that quickly refine and propel their works deep into society, they pass from the status of curiosities to essentials as societies are drawn to the flame of nonstop innovation.

If we were to frame the issue of obligate creativity for a hypothetical social species such as a super-innovator sapient ant or a novelty-genius penguin, talk of a creativity drive or an innovation instinct might suffice to orient the debate. In species that already use extensive innate hardwiring of neural circuits to run their behavior, it is not hard to envision Darwinian steps by which, under appropriate circumstances, genetic changes tweak the innate wiring and so boost the time allocated by the organism to novelty behavior. Such talk will not do for human beings however. Our brains are not hard-wired. For the human species, gene-culture coevolution has favored psychological development through gene-culture transmission, which we saw allows developmental gene activity to shape the elastic properties of cognition and mental activity without rigidly determining it.

Sociobiology therefore reminds us that in the instance of human creativity we must set aside the seductive talk of innate drives and instincts sometimes applied productively to other species. That is not the gene-culture way. There is instead the

human necessity of conscious choice and deliberation rather than hardwired drives. Supreme intellect and domain mastery, however spectacular in themselves, ultimately are no more than servants of an individual capacity for elective action, a specific moral stance taken in the face of known alternatives, which transforms a potential "I could create" into the passionate "I must create." For the obligate creator, giving oneself over to a life of creation, newness, and change is not optional. It is simply the right thing to do, and the lives so lived become wellsprings of novelty. In an organism endowed with a species-universal conscious grasp of notions about right and wrong, no choice about innovation can escape the winnowing filter of these culturally transmitted moral ideas and their diverse modes of expression across human cultures. Aside from the alien concerns of the life-destroying psychopaths and sociopaths who haunt the shadows of literature and cinema, gene-culture coevolution opens evolutionary time to the ascent of species like ourselves, in which creativity must have both a light and a dark side. One may create for both right and wrong reasons, with good and bad consequences. Creativity and morality, in the sociobiological perspective, are inseparably linked.

For the Rest of Us . . .

Where did the obligate creators come from? Well first of all we can be assured they exist. Glance along the index list of this encyclopedia and names of obligate creators jump out as favored subjects of inquiry among psychologists of creativity. Their achievements make them so: no fecundly creative moral being is fated to a dull life. They are the Mozarts, Einsteins, Edisons, Austens, Michelangelos, O'Keefes, and Caesars of human history. The biographies and histories of their lives chart the unscaled heights which seized their imaginations and the hard paths followed upward, where others might have turned aside. Historiometricians and social psychologists, bent to the task of counting innovations per lifetime and life stage, have long noted the sunburst of inventiveness enjoyed by a very few among those drawn to the creative life, and the disproportionate impact such lifelong creative production can achieve. We can also be assured the obligate creators have not been among us for long; obligate creators are something new under the Darwinian sun. They must be, else the archaeological and fossil records would strain with the detritus of their discarded inventions and works and their effect on the direction and speed of social change.

I have said that, among evolutionary sciences, sociobiology's hallmark is its focus on large-scale (population) patterns of social organization, and the relation of these patterns to the behaviors of the individuals comprising the society. Sociobiology can therefore be expected to help illuminate the evolved traits of societal organization that facilitate or impair the emergence of obligate creators, the impact of various schedules of innovation and creativity on the lifetimes of civilizations and the empires they fuel, and the timing of their creative outpourings in gene-culture coevolution. Can sociobiology and its methods of gene-culture coevolution help determine, for example, if the obligate creators long have been dormant within our species' epigenetic rules for mental development, awaiting only the right societal conditions to step forth? Or was

the Paleolithic's creative explosion the hallmark of a new genotype announcing itself in our ancestral tree, a transition that gave life on Earth access to obligate creativity for the first time? How often do obligate creators appear in history and why? How do their works and the lessons of their lives affect the rest of us, in terms both of material (bioeconomic) and spiritual import? Why do the world literatures and arts they have seeded brood upon certain patterns of conflict and struggle among the sexes, among the haves and have-nots, and among gods and heroes (Darwinian poetics)? When they favor creativity's dark side, what offers protection? Obligate creators are still more easily named than defined in rigorous abstract terms – we know them when we see them – but their nature and their role in the gene-culture circuit are central mysteries of human sociobiology.

The clues to these mysteries are enticing. All cultures of which we have knowledge sustain innovation and the creation in sanctioned areas, as well as their eager appreciation, critique, and use, although the directions in which creativity are expressed and channeled are culturally diverse. In this age of computers and large databases, the historiometry of innovation is an abundantly practical discipline, yielding striking evidence, through the work especially of Dean Keith Simonton and others, of nonmonotonic patterns of change in the form and content of works valued for their instrumental utility and/or as art objects. As we see throughout this encyclopedia, key relations between individual creativity and these societal patterns of creativity, innovation, and change are documented by the behavioral and social sciences, involving facets of the imagination, personality, intelligence, motivation, socioeconomic status, cognitive development and education, mood and psychopathology, enculturation, and cognition. Although individual creative potential and its action in everyday life are universal among members of our species, the most successful of the obligate creators anchor one end of a spectrum (apparently characterized by abruptly curvilinear fall-off) of those marked differences in creative output and impact. Very few of us innovate in a way that changes society in a big way, more find creative appreciation (and critique) at some level, and all of us come up with novel solutions when unexpected guests drop in for dinner.

There is a significant weakness in current writing about the evolutionary origins of this creative potential and its release through obligate and everyday creativity. So far, there are just too many good stories one can tell – given the impressive but limited evidence in hand – about why a disposition to innovate and adopt might help a naked ape cope with gene-culture coevolution. The Darwinian scenarios include creativity's uses in exploiting abrupt changes in group structure; the benefit of persuasion, cheating, lies, and seduction to self, kin, and allies; grabbing the attention of the powerful; improving gene-culture fitness because you're the one to copy; collecting mates; and so on. The interested reader will find these and other diverse possibilities explored in *Further Reading* and *Relevant Websites*. There is value in such diversity of course; it gestures toward the creative work still waiting on the road to explain the creative mind. Sociobiology and creativity psychology are young sciences in the grand scheme of things, and their transition from speculative scenario to testable evolutionary hypothesis encompassing creativity, consciousness and morality is human sociobiology's central challenge.

I am not trying to be evasive at this point. We cannot achieve effective evolutionary treatments of creativity and innovation until the specific manner in which our human minds engage in those activities is established, and established in a way that allows conceivable alternatives to be stipulated and evaluated in terms of their effectiveness within a process of gene–culture coevolution. A mammoth order for creativity research to be sure, but this is the era of an emerging scientific grasp of the specific cognitive, affective, social, and moral processes at work in the creative mind. Once we know better what these processes are and how they correlate with history and social form, we will be in a better position to explain why they are so and not otherwise. In the interim, sociobiology's consilient worldview reminds us that while all may – for now – opine on creativity's origins and meaning, none can decree which among creativity's endless possibilities the future one day will cherish.

Glossary

Elaboration A person's ability to add pertinent details (more ideas) to the minimum and primary response to the stimulus figure.

Father education A course of study that a father has successfully completed or an exam that he has passed.

Father income The money that is earned by a father from work/business.

Father occupation The type of work performed/the type of work for which a father is qualified.

Flexibility A person's ability to produce differences in the trend of thought. All those ideas that differ in approach or trend are treated as one for the purposes of flexibility scoring.

Fluency In scoring for fluency, a scorer goes through the responses to the item in question carefully and strikes off those that are irrelevant and/or have been repeated.

The remaining number of responses is the fluency score.

Mother education A course of study that a mother has successfully completed or an exam that she has passed.

Mother income The money that is earned by a mother from work/business.

Mother occupation The type of work performed/the type of work for which a mother is qualified.

Nonverbal creativity Nonverbal creativity refers to a fairly specific type of cognitive ability reflected in performance on a series of paper-and-pencil tasks. There are three nonverbal tasks, namely, picture construction, picture completion, and triangles and ellipses.

Originality The uncommonness of a given response. Responses given by less than 5% of the group are included and are given different weights.

Overall creativity Composite scores of verbal and nonverbal creativity scores.

Socio-economic status Socio-economic status (SES) variable is to be considered as the sum of the scores awarded for father's and mother's education, father's and mother's occupation, and average monthly income of the parents rather than the wealth and place of residence.

Verbal creativity Verbal creativity refers to a fairly specific type of cognitive ability reflected in performance on a series of paper-and-pencil tasks. There are four verbal tasks, namely, consequences test, unusual uses, new relationships, and product improvement.

Socio-Economic Status

The term 'socio-economic status (SES)' refers to an individual's position in a society which is determined by wealth, occupation, and social class and is a measure of an individual's or group's standing in the community. It usually relates to the income, occupation, educational attainment, and wealth of either an individual or a group. These types of variables are summarized into a single figure or socio-economic index. There is no general agreement on the definition of SES and so different socioeconomic indexes are constructed for different uses.

According to Sharan in 1986, SES is a mental construct, a degree of esteem or lack of esteem which people in society display toward an individual. High SES, therefore, indicates a high income, high status occupation and adequate living conditions, whereas, low SES refers to poor income, low occupation, and inadequate living conditions. High SES is considered to provide a healthy and enriched stimulating environment in which personality may develop appropriately, whereas children of low-income groups may develop feelings of insecurity and inferiority and an unhealthy attitude toward people and objects.

SES and Creativity

SES depends on a combination of variables, including occupation, education, income, wealth, and place of residence. But usually, the SES variable is to be considered as the sum of

the scores awarded for father's and mother's education, occupation, and average monthly income of the parents rather than the wealth and place of residence.

According to MacKinnon in 1962, a child from a low SES background is generally left on his own to a greater extent and is permitted to freely move around, explore, and form his own ideas. Though this latitude on the part of the parents is incidental and not deliberate, it certainly has a liberating influence on the child which is likely to enhance his creativity. Family SES has itself been directly related to creativity.

SES has been found to be a significant factor in most of the cognitive and psychomotor performances. It enters indirectly into learning and is regarded to bear some relationship with creativity. The reasons being that a family enjoying a high score SES is able to provide for conditions and facilities conducive to the growth of creativity and vice-versa. Social class differences in creativity have also been explored in a number of studies but the evidence arrived at has not been unequivocal. Arguments have been given to justify the incidence of creativity amongst low as well as high socio-economic background.

SES and Performance on Creativity Tests

There is a large empirical literature, both in India and abroad, showing the relationship between SES and creativity although a few contradictions are found here and there. However, all these studies show that much of what we know is based on psychometric assessment of creativity.

In 1980, Singh studied student teachers and concluded that all three indices of family background, viz., education, occupation, and income of the father, were quite significant in determining the development of creativity.

According to Singh in 2007, SES appears to be more instrumental in fostering or hindering creativity among children than any other determinants. Studies related to the SES of creators show that they come from an average SES in which children tend to be creatively stimulated and encouraged to create something new and original.

In 1965, Smith found that among fifth-grade white children in Pittsburgh, the middle class performed significantly better on verbal tasks, but the lower class excelled on nonverbal items. Dewing studied that the correlation between creativity and SES was highly significant. Ogletree and Ujlaki in a cross-cultural study of English, Scottish, and German subjects observed in 1973 that in all countries the creativity scores of the upper class were significantly higher than those of the middle- and lower-class samples. McDaniel indicated in 1974 that subjects from a higher SES performed better on creativity than those from a lower SES.

In 1979, Forman found that upper class children scored better than lower-class children on creative measures. An empirical study by Heinla in 2006 on 16–17-year-old Estonian adolescents' and 9–12-year-old children's creative thinking indicated a connection with parents' profession and the family economic status. The study results demonstrated that the creative thinking of 16–17-year-old adolescents is higher in the group where one or both parents have university education, work as top executives or specialists, where the families cope well economically, and live in the capital. The creative thinking of the 9–12-year-old children is higher in the group where the mothers have a higher education and when they live in a rural area.

In India A. K. Sharma, revealed in 1979, that students of upper SES scored significantly higher on creativity than students of upper middle, lower middle, and upper lower SES. Other researchers have found similar results.

In 1979, Awasthy reported that students of very high SES were superior to the students of high, average, and low strata SES in flexibility, originality, and total creativity, while students of high SES were superior to the students of very high, average, and low strata SES in fluency. The results of Sharma and Jarial

support the above results, whereas those of Sharma were different. Students of high SES scored significantly higher than the students of low SES in fluency, whereas no significant difference was found in the flexibility, originality, and total creativity scores of these groups.

In 1980, Ahmed found a significant difference in the verbal and nonverbal creativity of students coming from advantaged and disadvantaged home backgrounds, favoring the former.

Some studies have revealed that in India there is no significant difference in the creativity scores of high, middle, and low SES students.

An empirical study by Sebastian in 1997 with 398 children of 13–15 year age group from the Ernakulam district of Kerala, India revealed that the correlation matrix on overall creativity, verbal creativity, nonverbal creativity, and its dimensions are positively and significantly related to overall SES and its variables except mothers' occupation and status, the coefficient values ranging from $r = 0.32$ to 0.46 , all $p < 0.01$. Thus in the study it is found that the creativity of children increases with higher SES of their families including fathers' education and occupation, mothers' education, and monthly income of the family excluding mothers' occupation.

Mothers' occupation is not found to be related to verbal creativity and its dimensions, and the overall creativity. However, a low significant relationship is observed between mothers' occupation and nonverbal creativity ($r = 0.15$, $p < 0.01$). No relationship is observed between mothers' occupation and its dimension, and the elaboration of nonverbal creativity.

Another empirical study undertaken by Sarsani in 1999 with a sample of 373 students reveals that father's and mother's income was highly correlated with their education ($r = 0.38$, $p < 0.0001$ and $r = 0.19$, $p < 0.001$) and with occupation ($r = 0.31$, $p < 0.0001$ and $r = 0.58$, $p < 0.0001$). Father's education and mother's education was highly correlated with their respective occupational categories ($r = 0.36$, $p < 0.0001$ and $r = 0.27$, $p < 0.0001$). It is generally true that highly educated people have better opportunities to occupy good positions and earn more than any uneducated or middle educated group (Table 1).

From Table 1, a high correlation between father's education and mother's education ($r = 0.59$, $p < 0.0001$) reflects Indian socio-cultural practices. In India, marriages are normally settled by elders looking at various factors like education,

Table 1 Intercorrelations between students' parental background variables and creativity

Pearson coefficient of correlation (<i>r</i>)	Father			Mother			Children's creativity (CC)
	1. Education	2. Occupation	3. Income	1. Education	2. Occupation	3. Income	
Father							
1. Education	1.0	0.36****	0.38****	0.59****	0.18****	0.10*	0.15**
2. Occupation		1.0	0.31****	0.33****	0.09#	0.04#	0.07#
3. Income			1.0	0.38****	0.05#	0.14**	0.12*
Mother							
4. Education				1.0	0.27****	0.19***	0.17***
5. Occupation					1.0	0.58****	0.11*
6. Income						1.0	0.16**
7. Children's creativity (CC)							1.0

**** = Significant at 0.0001; *** = Significant at 0.001; ** = Significant at 0.01; * Significant at 0.05; # = Not significant.

Source: Sarsani (1999) (unpublished Ph.D. thesis).

occupation, and earnings. For example, a highly educated person looks for a highly educated bride. Of course there are some exceptions.

As for creativity, it was found that it correlated highly with mother's education ($r=0.17$; $p<0.001$), mother's income ($r=0.16$; $p<0.01$), father's education ($r=0.15$; $p<0.01$), moderately with mother's occupation ($r=0.11$; $p<0.05$), and father's income ($r=0.12$; $p<0.05$). There was no significant relation with father's occupation.

Parental Education and Children's Performance on Creativity Tests

In 1962, Getzels and Jackson found that the parents of the high IQ child also tended to have a somewhat higher educational level than the parents of the high creativity child. But what is perhaps more noteworthy is the greater specialized training of both the mother and the father of those with high IQs. A greater proportion of the high IQ fathers than of the high creativity fathers were found in academic or educational occupations. But, despite their greater professional training, a somewhat greater proportion of the mothers of the high IQ children than of the high creativity children were exclusively housewives and did not hold other full or part-time jobs. It would seem that the mothers of high IQ subjects had more time to devote to their children than the mothers of the highly creative subjects. High IQ mothers were in fact likely to be more vigilant about the 'correct' upbringing of their children than the high creativity mothers.

According to Runco, SES is relevant to creativity and its development in part because SES determines what kind of experiences and resources will be available. Additionally, parental education is correlated with family SES, and parental education by itself plays a large role in development. It determines communication patterns and content, for example, and conveys the idea that education is a valuable thing. SES may also determine how wide a range of experiences a child will have in terms of travel, but also in terms of the books that may be available, the range of people who may visit the home, and the cultural experiences (e.g., museums, theatres) the child will visit.

In India, Sudhir Kumar reported that father's education and mother's education were found to foster higher creative thinking ability; the students with well-educated parents attained higher creativity scores than those with illiterate parents. Parental occupation was not found to be a factor related to the creativity of children.

In 1968, Raina found that a higher creative group came from parents who were comparatively better educated than the parents of lower creative students. In 1977, Srivastava also observed that the children of highly educated parents scored significantly higher than the children of less educated parents on a creativity test. A more recent study revealed that parents' higher level of education was a favourable factor for the development of creativity in their children.

In 1999, Sarsani studied whether significant mean differences existed among the students in relation to their fathers' education level. It was found that the differences in verbal creativity were statistically significant ($F=2.97$, $p<0.001$) between groups of students based on their fathers' educational qualifications. In component-wise analysis, except in verbal

fluency, the mean differences were found in the components of creativity such as verbal originality and flexibility. It was found that there are no significant mean differences among the groups in nonverbal creativity and its component nonverbal elaboration, but not in nonverbal originality.

As for overall creativity (verbal + nonverbal), the F -ratio was found to be 3.32 which is significant at the 0.01 level. There were significant differences between the groups. Except for the group whose fathers were illiterate, there was a significant increase in the mean score obtained by the students whose fathers had higher education levels. Generally, better education in fathers relates to greater creativity. Why the children with illiterate fathers do not fall into this pattern is not clear and requires further research.

In the case of mothers, an analysis of variance (ANOVA) for verbal creativity ($F=2.89$, $p<0.01$) and its component verbal originality ($F=4.83$, $p<0.001$), and verbal flexibility ($F=2.20$, $p<0.05$), indicates significant mean differences among the groups whose mothers had different educational backgrounds. But no differences were found in verbal fluency.

In nonverbal originality, elaboration, and total nonverbal creativity, no significant differences were found among the groups whose mothers have different educational backgrounds.

Lastly, an ANOVA was performed on the overall creativity scores (verbal + nonverbal) in order to examine the variation in the means obtained by the students whose mothers had different educational backgrounds and was found to be significant ($F=2.16$, $p<0.05$). Overall, the greater the level of the mother's education the higher the level of verbal creativity. This did not apply to nonverbal creativity, where the difference was insignificant. Even in verbal creativity, the relationship was not always linear.

Parental Occupations and Children's Performance on Creativity Tests

The fathers' occupations were classified by Sarsani under eight categories on the basis of the National Classification of Occupations. The results reveal nonsignificant differences in mean scores of verbal originality, fluency, flexibility, and total verbal creativity among groups with different fathers' occupation levels. Similar nonsignificant results in nonverbal originality, nonverbal elaboration, and total nonverbal creativity were reported. This indicates that the fathers' occupation does not influence their child's creativity.

As far as overall creativity was concerned, the obtained mean differences among the different groups were not significantly different ($F=0.46$, $p>0.05$).

The mothers' occupations were classified under the same categories as fathers' occupational categories. The verbal originality indicates significant mean differences among the groups whose mothers had different occupational backgrounds ($F=3.10$, $p<0.05$). No significant differences were found for verbal fluency or verbal flexibility. However, a significant difference was found for total verbal creativity ($F=2.30$, $p<0.05$).

Nonsignificant differences were found for nonverbal originality, nonverbal fluency and total nonverbal creativity. Finally, a nonsignificant mean difference was also found in overall creativity. Generally, where mothers are working in higher level occupations their children's verbal creativity is higher. This does not apply to nonverbal creativity.

Parental Income and Children's Performance on Creativity Tests

A correlation matrix (Table 1) shows the Pearson 'r' correlation coefficient on the set of SES variables. There are other indicators of SES, such as ownership of land, buildings, cars, televisions, refrigerators, etc., but asking all these particulars may be misunderstood and may not give reliable information because of possible income tax avoidance or legal problems. There are no problems in disclosing education and occupation. Of course the income reported may not be 100% correct but, when verified with the school records confidentially, were found to be generally accurate.

The results reveal nonsignificant differences in mean scores of verbal creativity and its components verbal fluency and flexibility among groups with different fathers' income levels. However, verbal originality was found to be significant ($F=2.68$, $p<0.05$). With regard to the nonverbal creativity and its components, originality and elaboration, the differences in means were also not significant.

As far as overall creativity was concerned, the difference was not significant. It can be interpreted that fathers' income, overall, does not appear to influence their children's measured creativity.

Significant differences was found among groups with different mothers' income levels in verbal creativity ($F=3.31$, $p<0.01$) and its all components such as originality, fluency, and flexibility. The children of the highest income groups obtained higher scores than the lower income groups. Nonsignificant means differences were found for nonverbal creativity and its components, such as originality and elaboration.

As far as overall creativity was concerned, the difference was significant ($F=2.88$, $p<0.05$). The highest income group scored the highest and the lowest income group (or no income) achieved the least mean score on overall creativity. Again, the main influence appears to be on verbal rather than nonverbal creativity.

Conclusion

Overall creativity (verbal + nonverbal) scores were related to children's parental background, with better education, occupation, and income leading to higher levels of creativity. When parents were considered separately there were exceptions. The children of illiterate fathers seemed to score more highly

than those with more education. Why this might be so is not clear. With regard to the mother, the better educated the mother the higher the level of verbal creativity. This did not apply to nonverbal creativity. Fathers' occupation did not influence creativity, but for mothers, where higher levels of occupations were held, children tended to have better verbal creativity. Similarly, it was the mother's income, not the father's, which differentiated verbal but not nonverbal creativity. Overall, the research studies in India and abroad tends to suggest that there is a relationship between SES and the creativity trait. It can be interpreted that the higher the level of SES the greater the chances of one being creative.

Glossary

Absorption Undistracted, deep cognitive/affective involvement with, and heightened sense of reality toward, attentional objects.

Contemplation The intentional act of deep thoughtful reflection, consideration; reflexive thought on the relationship between self and other; meditation on spiritual matters.

Dark energy Hypothetical form of energy permeating all of space that tends to increase the rate of expansion, dispersion, of the universe; a form of vacuum energy derived from the quantum physical uncertainty principle.

Dispassion The ability to detach from fixed interpretations of reality which supports qualities like openness, empathy, wisdom, creativity, and spirituality.

Mystical experience A deviation from ordinary conscious awareness which transcends ordinary experience and manifests as a direct, intimate, and intuitive encounter with a reality of a higher order of magnitude.

Singularity A singular point near which functions deriving information tend towards zero or infinity exhibiting extreme behavior; in astrophysics, a space-time point at which gravitational forces cause infinite space/time distortion where matter exhibits infinite density and infinitesimal volume.

Spirituality *Emmons* Search for meaning, unity, connectedness to nature, humanity, and the transcendent.

Synesthesia The ability to transform, enrich, and encode events in multiple sensory modalities in an absorbing manner.

Transcendence Knowledge of how objects (information) are experienced or constituted as objects; a form of conscious awareness that lies beyond the immediate grasp of the intellect; also, awareness of the infinitude of unrealized informational possibilities.

Transliminality *Thalbourne* The tendency for psychological material to move, in and out, across the threshold of consciousness.

Setting the Stage

One of Nature's greatest wonders is that a species devoid of fangs, claws, body armor or camouflage and whose young rely on extended nurturing for survival, should become the dominant species on this planet. The only advantage it had was a conscious awareness, and memory, of its limitations coupled with a sense of agency that other species did not have. Human awareness of sickness, old age, and death (SOD) probably predates the Paleolithic (2.5 million years ago), an era where hominids like *Homo habilis* first began forming stone tools. As SOD is usually unpleasant and ultimately terminal, early man found ways to deal with it. He discovered that natural phenomena like earth, wind, fire, water, and living things could be harnessed to improve and extend life. He developed language which led to the rise of civilization. He also realized his capacity for creative problem solving as well as the value of innovation and progress. There were times, however, when Nature appeared to be malevolent, beyond his willful control. He observed that, in such circumstances, surrendering to Nature's unknown, sacred power via chanting, prayer, and making offerings would occasionally appease his situation. Weather cleared, disasters were miraculously averted, and family members were saved or healed. The beneficial effects of expressing his humility, however, were not as guaranteed as the effects of progress. Assuming his knowledge, will and actions to be somehow deficient, he sought a deeper relationship with the sacred to establish meaning in his life. This goal gave rise to shamanism, and eventually religion. In man's search for meaning, along with his desire for progress,

he noticed an unusual phenomenon: the most productively creative individuals exhibited what Plato later called 'divine madness.' Creative inspiration somehow also had a mysterious, sacred quality to it.

Far removed from prehistoric times, modern man's battle with SOD continues. Technologies, for instance, involving biochemistry, bio-engineered clones and stem cells, high-speed computation and artificial intelligence promise healthy, extended lives. Yet, regardless of the tremendous progress in science, Nature's greatest mysteries remain an enigma. Entropy is unabated and immortality's out of reach. Philosophy, the study of truth, has been unable to resolve a single fundamental question and man's spiritual inclinations stand firm against the alluring explanatory powers of physicalism and materialism. The forces that motivate creativity and spirituality are still an open question. The purpose of this article is twofold: (a) to shed light on the ancient, profound relationship between two equally essential phenomena, creativity and spirituality; and (b) to open that relationship to future scientific scrutiny. Empirical investigation into the relationship between these two constructs is rare because spirituality, a common term related to overall purpose and existential meaning within diverse contexts, remains ill-defined and therefore almost opaque to measurement while creativity, though more specifically defined and hence measurable, displays tremendous breadth across multiple knowledge domains for discovering original problems, solutions, and expressions. In short, the relationship is bound to be both profound and complex, and so this article can only hope to serve as an initial probe into this vast subject.

Transcendence Manifested

The word spirituality is derived from the Latin *spiritus* which refers to breath as the vital, animating principle of life. Breathing is a dynamic process involving periodic oscillations between inspiration and expiration. In the Christian tradition, the gospel of John starts with "In the beginning was the Word . . ." Here, 'word' implies transcendental meaning, or knowledge, carried by the breath, or spirit, of God. In Hinduism, the Vedas speak of the primordial word *ParaVak* as the vibratory origin of the universe. Buddha, in the *Aggañña Sutta*, described a pulsating universe, expanding and contracting via natural causes over countless eons. Spiritual evolution, similarly, pulsates in a dynamic interplay between transcendence and immanence, between knowing as Being and knowing as grasping. According to Islam, and other theistic traditions, Nature's duality was created by God: "The heavens and the earth were of one piece, then We parted them" (Koran 21:30, Marmaduke Pickthall, 1992: 330). Spiritual evolution mirrors the divine creative process. It follows a spiral path to Truth, oscillating at increasingly subtle levels between inspiration and expression.

Robert A. Emmons defined spirituality as "a search for meaning, unity, connectedness to nature, humanity and the transcendent" (Robert A. Emmons, 1999: 877). Although spirituality is incumbent in religiosity, individuals describing themselves as spiritual may not consider themselves religious. David C. Dollahite defined religion as "a covenant faith community with teachings and narratives that enhance the search for the sacred and encourage morality" (David C. Dollahite, 1998: 5). In 2000, Peter C. Hill and others construed sacred as an individual's perception of a divine being or object, ultimate reality or ultimate truth. Search for the sacred, interpreted in accordance with specific beliefs and culture, is the common denominator for religion and spirituality. A study by Gerard Saucier and Katarzyna Skrzypińska, in 2006, indicated that spirituality and religiousness produce two highly independent dispositions. While *tradition-oriented religiousness* is associated with authoritarianism, traditionalism, collectively shared beliefs and low openness to experience, *subjective spirituality* has a mystical orientation highlighting the value of subjective experience. It is associated with absorption, fantasy-proneness, dissociation, magical thinking, eccentricity, and high openness to experience. The same descriptors have also been attributed to creative individuals.

Roy Horan defined creativity as the "manifestation of an intention to transcend the limitations of information" (Roy Horan, 2007: 182). He construed creative intention as both conscious volition and as an unconscious stream of attention directed toward a goal. In this respect, the state of transcendence precedes the integration of new information, or insight. His definition could easily apply to spiritual transformation, or self-actualization, wherein manifestation appears as a more psychologically integrated, insightful individual. The experience of transcendence supports both creativity and spirituality by altering common perceptions and habitual thought patterns. Spiritual transcendence involves a direct intuitive experience (revelation) of a higher self (or Being) which Merrill-Wolf, in 1995, argued occurs when the light of consciousness reverts upon itself, a way of knowing he calls *introception*. In creativity,

transcendence lies in the infinite realm of possibilities and in information gaps where, according to Amit Goswami in 1999, cognitive quantum leaps provide a mechanism for new associations to form. In both creative and spiritual processes, the normal interpretive intellect is momentarily breached, a phenomenon which manifests in openness to experience, sensitivity, absorption, synesthesia, dispassion, transluminance, unitive experiences of self-other, mysticism, during moments of inspiration and psychological freedom.

Sensitivity, Openness, Absorption, and Synesthesia

Earle J. Coleman's book entitled *Creativity and Spirituality: Bonds between Art and Religion* provided a broad overview of the relationship between artistic creativity and spirituality. One of the commonalities, he argued, is receptivity, or openness. He suggested that an esthetic orientation encourages the artist to wholly engage natural phenomena by developing rapport, empathy, and sympathy towards Nature. The native American, Walking Buffalo, illustrated this spiritual-aesthetic orientation, "We saw the Great Spirit's work in almost everything: sun, moon, trees, wind and mountains. Sometimes, we approached him through these things" (Walking Buffalo, 1971: 23). William James, in 1958, called this religious approach to natural phenomena a 'mood of welcome' (William James, 1958: 49). The mystic-poet, William Blake, in *Auguries of Innocence*, elevated this open aesthetic to another level:

To see a world in a grain of sand,
And a heaven in a wild flower,
Hold infinity in the palm of your hand,
And eternity in an hour
(David V. Erdman, 1982: 490)

Heightened aesthetic sensibility in creative and spiritual experience touches the very core of an individual's being, evoking deep emotions like awe, wonder, and ecstasy. Aesthetic sensibility suggests increased physiological sensitivity. In 1996, Colin Martindale and others compared galvanic skin response to creativity scores. They found that creative individuals are more sensitive to physiological stimuli, stay alert toward incoming stimuli regardless of having developed cortical models for them, demonstrate larger fluctuations in arousal levels, and habituate more slowly than less creative individuals. Sensitivity is also important to spiritual development. Meditation forms the central practice of many spiritual traditions. In 1999, Michael Murphy and Steven Donovan cited numerous neuropsychological studies supporting meditation's capacity to enhance empathy, sensitivity to stimuli and overall perceptual ability. Terry V. Lesh, for example, found in 1970 that Zen meditation increased sensitivity, openness to experience, and empathy in counseling students. Emotional sensitivity, however, is more common to artists than scientists.

Robert R. McCrae and Paul T. Costa, Jr, in 1985, indicated that openness to experience, an attribute significantly correlated to creativity, is related to scope of awareness and depth/intensity of consciousness. It is positively correlated with the need for variety, preference for complexity, tolerance for ambiguity, nontraditional attitudes, behavioral flexibility, rich, complex and ambivalent emotions, perceptual synesthesia, and is

negatively correlated with dogmatism. Gregory J. Feist, in 1999, noted that openness to experience is found in both creative artists and scientists. McCrae and Costa further noted that openness to experience positively correlated with the Tellegen Absorption Scale. In 1974, Auke Tellegen and Gilbert Atkinson argued that absorption is the capacity for self-absorbed, self-altering attention found in peak and mystical experience, hypnosis, and artistic creativity. Absorption is a readiness for undistracted, deep cognitive/affective involvement and a heightened sense of reality toward attentional objects. It permits the assessment of information in unconventional and idiosyncratic ways. In 1981 and 1987, Charles M. Rader and Tellegen discovered a significant correlation between absorption and synesthesia which is defined as the ability to transform, enrich, and encode events in multiple sensory modalities in an engaging manner. Synesthetes are noted to be very creative. Furthermore, many artistic works and spiritual texts bear descriptions of a synesthetic nature. Thirteenth-century Sufi mystic-poet Jaladin Rumi's *Ode 314* is one example:

Those who don't feel this Love
pulling them like a river,
those who don't drink dawn
like a cup of spring water
or take in sunset like supper,
those who don't want to change,
let them sleep
(Coleman Barks, 1990: 18)

Openness to experience, sensitivity, absorption, and synesthesia exhibit the quality of transcendence by detaching from existing informational patterns. They also intensify in profound artistic and religious experience.

Dispassion

Coupled to absorption is a capacity for what Horan, in 2007, translated as dispassion (*vairāgya*), an individual's ability to detach from fixed interpretations of reality, a quality which promotes openness, empathy, wisdom, and creativity. This construct is exemplified in the story of Śikhidvaja and Cūdālā in the *Yogavāsīṣṭha*, a renowned Hindu scripture illustrating the power of the mind. Cūdālā, the queen, teaches her husband, Śikhidvaja, that spiritual enlightenment cannot be attained by detachment from material things or even the body (asceticism), but by detachment from closely-held assumptions and interpretations of reality. Asceticism, or self-denial, is a common spiritual practice in monastic settings. In attempting to transcend desire, asceticism may promote a sense of separation from material phenomena eliciting, in response, a clinging to the concept of detachment itself which forms a major obstacle to spiritual evolution. If not approached properly, detachment can also lead to pathologically disassociated states. On the other hand, Donald G. Forgays and Deborah K. Forgays, in 1992, noted that sensory deprivation, a form of induced detachment, elicited creativity. In this respect, sense withdrawal acts as a constraint. Although the neuropsychological mechanisms connecting creativity to sensory deprivation are unclear, one could speculate that sensory inhibition activates the hypnogogic state. This ambivalent waking-to-sleep state has inspired many creative individuals. In meditative

traditions, hypnogogic reverie is considered a dispassionate first step toward transcendence. Jesuit priest Anthony De Mello described the open affective nature of dispassion: "You cannot love what you are not constantly discovering anew, the object of affection may be an artwork or natural beauty as well as a human or the divine" (Anthony De Mello, 1992: 97–98). This love arises by constraining the tendency to concretize interpretations of experience. In science, dispassion takes the form of objectivity which continually challenges basic assumptions and rediscovers the nature of truth, an approach that has stimulated an exponential growth in innovation and technology.

Transliminality

Another form of psychological transcendence, or loosening of informational boundaries, is transliminality, which Michael A. Thalbourne defined as a "hypothesized tendency for psychological material to cross thresholds in and out of consciousness" (Michael A. Thalbourne, 2000: 196). Transliminality is a form of psychic mobility that occurs across the threshold of awareness. In 2000, Thalbourne and James Houran found that transliminal subjects had greater belief in parapsychological and unusual events, reported more of these experiences, felt themselves to have powerful minds and demonstrated a proclivity for introspection, daydreaming, and altered states of consciousness. These descriptors are evident in many spiritual individuals. Thalbourne, furthermore, observed that the *Creative Personality Scale* had a significant correlation with transliminality as well as with the above-listed attributes; however, other measures of creativity like the *Revised Barron-Welsh Art Scale*, a measure of figure-complexity preference, did not support transliminality. This suggests that not all creative criteria involve transliminality. What has not been investigated is the distribution of transliminality in creative artists and scientists. In 1997 and 2001, Thalbourne and others noted that high transliminals are likely to report synesthesia-like experiences perhaps as artistic metaphor or via drug use, and hyperesthesia, a heightened sensitivity to sensory stimulation. EEG studies conducted by Jessica I. Fleck and others, in 2008, on high transliminals found reduced coherence in the low alpha/high beta range within the right temporal lobe which is consistent with studies of participants with high paranormal beliefs as well as creative individuals during baseline recordings.

Union of Self-Other

One of the primary transcendental phenomena observed in both creative and spiritual individuals is the perceived union of *self* and *other*. Coleman suggested that while the intellect tends to separate subject from object, aesthetic intuition and spiritual experience undermine this separation, often resulting in an ineffable harmony. Philosophical positions on the self-other union differ. While Christian mystics like Saint John of the Cross and Teresa of Avila suggested that monism is psychologically true but ontologically false, Advaita Vedantins declared the existence of a single ontological Reality (*Brahman*) in which the self and material world are merely appearance, or *maya*. The Upanishads refer to this as *Tat Tvam Asi* – That Thou Art. Coleman argued that absolute transcendence, or annihilation of the self, does not allow for important spiritual qualities like devotion or transformative creative processes. Annihilation

of the ontological separation between self and other, unless transient, is unimaginable because consciousness would be destroyed. Consciousness implies consciousness of something, even if that something is consciousness itself. Furthermore, Reality's creative power (even as *maya*) is virtually undeniable. Creativity permits immanence which, along with transcendence, describes ultimate reality in many religions. Though the Advaita Vedantins stress transcendence, they still account for appearances.

The union of self and other is a common theme in art. For example, the Chinese copy master painters, or sculptors, to perfection in order to experience the masters' creativity at a deeper level. Coleman suggested that Leonardo da Vinci implied this in saying, "He who cannot become the object cannot draw it" (Earle J. Coleman, 1998: 96). That is, an object also reflects its creator. Science tends not to acknowledge unitive self-other states because they belie the construct of measurement, and therefore objectivity. Quantum physics, however, has challenged this perspective. Werner Heisenberg stated, "The common division of the world into subject and object, inner world and outer world, body and soul, is no longer adequate and leads us into difficulties" (Werner Heisenberg, 1958: 24). Similarly, David Bohm declared, "Relativity and quantum theory have shown that it has no meaning to divide the observing apparatus from what is observed" (David Bohm, 1983: 143). The phenomenon of creativity, applying the quantum physical model, results from both Nature's spontaneous and the observer's conscious (or unconscious) choices which affect the probability of original information coalescing within a transcendent state (i.e., the quantum vacuum).

Most empirical investigations of the self-other union focus on the neuropsychology of mystical states and the practices that induce them. David M. Wulf, in 2000, defined mystical experience as a deviation from ordinary conscious awareness that leaves the indelible impression of encountering a reality which transcends ordinary experience at a higher order of magnitude. The mystical experience is often a defining moment leading to positive psychological transformation. Evelyn Underhill suggested that the ultimate transformation of the mystic includes a higher order of creativity:

... the mystic's personal encounter with Infinite Reality represents only one of the two movements which constitute his completed life. He must turn back to pass on the revelation he has received He is, in fact, called to be a creative artist of the highest kind . . . (Evelyn Underhill, 2003: 65)

In 2001, Andrew Newberg, Eugene d'Aquili and Vince Rouse, using single positron emission computerized tomography (SPECT), scanned Tibetan monks and Catholic nuns during meditation and prayer. They discovered reduced activity in the posterior superior parietal lobe (PSPL) and increased activity in the right prefrontal cortex (RPF) which they felt caused the sensation of absorption of the self into something larger. The PSPL is responsible for defining the boundaries of the self. It is also associated with creative insight. Decreased activity in the left PSPL results in a loss of self and reduced activity in the right PSPL enhances a feeling of unity with the world. They suggested that hyperactivation of the RPF stimulates the hippocampus to inhibit neuronal signals from reaching the orientation areas of the brain, thereby softening the self's boundaries. Roland

Fischer, in 1971, suggested that consciousness can be altered either via the *ergotropic* pathway of increased arousal ending in mystical ecstasy or, via the *trophotropic* pathway of decreased arousal ending in deep trance. Sometimes both pathways alternate in a single experience. The ergotropic pathway is founded in the sympathetic nervous system and exhibits higher EEG discharges while the trophotropic pathway is based on the parasympathetic nervous system and exhibits lower frequency discharges. In both cases, the boundary between observer and observed, between what is subjective and objective is blurred and the sense of time either accelerated or slowed. In 2009, Horan argued for a neuropsychological connection between creativity in incubation and illumination phases and meditation, resulting from *transcendence* and *integration*. Transcendence, reflected in low-alpha/delta brain-wave frequencies, surpasses informational limits while integration, reflected in theta/gamma frequencies, transforms and reestablishes informational boundaries. Mindful meditation (the technique of witnessing thoughts, emotions, and sensations until they subside) elicits information reduction, or transcendence, through dispersed attention while concentrative meditation (the technique of intently focusing on absorption-inducing vehicles) exhibits information reduction via focused attention. Both attentional strategies permit unitive self-other states, are not restricted to formal meditation, and are employed spontaneously to a greater or lesser degree by creative artists and scientists.

Mysticism, meditation, and prayer do not fully describe spirituality which contains a strong affective component associated with virtues like love, compassion, gratitude, forgiveness, and humility. Empirical investigations of spirituality as a psychological construct are quite limited, usually involving self-reports. Additionally, the affective relationship between creativity and spirituality is relatively unexplored.

Inspiration

The notion of creative inspiration being associated with the transcendent has deep roots in art, science, philosophy, and religion. Ancient Greek poets invoked the divine Muses for inspiration. The philosopher Philo once wrote "I have approached my work empty and suddenly became full, the ideas falling from a shower from above and being sown invisibly" (Abraham Joshua Heschel, 1962: 333). Similarly, the composer Johannes Brahms said "Straightaway the ideas flow in upon me, directly from God, and not only do I see distinct themes in my mind's eye, but they are clothed in the right forms, harmonies, and orchestration" (Willis Harman and Howard Rheingold, 1984: 46). In 1968, Srinivasa Ramanujan Aiyangar revealed that mathematical genius, Srinivasa Ramanujan had claimed his mathematical insights originated with the Goddess Namakkal, another way of saying he felt their origin to be transcendent. George Nugent Merle Tyrell, in 1946, cited the poet Percy Bysshe Shelly as saying, "One after another the greatest writers, poets and artists affirm that their work comes to them from beyond the threshold of ordinary consciousness" (Willis Harman and Howard Rheingold, 1984: 47). Even the scientific method, attributed to Rene Descartes, was predicated on the nonrational aspects of three dreams he had on the night of 10 November 1619. They occurred after Descartes failed repeatedly, while attempting

to unify science and mathematics, to reveal the mind of God. In 1977, Wassily Kandinsky wrote that Teresa of Avila attributed her literary work, *The Interior Castle*, to God. Rumi, ascribed his *Masnavi*, a collection of over 50 000 poetic lines, to divine inspiration. More generally, theologians suggest that scripture, which forms the basis of all major religions, is divinely revealed in its content and divinely inspired in its transmission or expression; that is, scripture emanates from without.

Inspiration emanating from within the individual, through intrapsychic forces, is a fairly recent idea. Eduard von Hartmann, in 1884, thought the unconscious mind produces more elegant and organic ideas than the conscious mind. In 1952, Ernst Kris described inspiration as regression in service of the ego; that is, cognitive regression toward primary processes occurs in order to facilitate flexible thinking and novel insight. In a similar vein, Ronald A. Finke, in 1995, suggested that the intentional merger of unassociated images stimulates the emergence of preinventive forms which lead to new inventions. Regardless of how inspiration is viewed, from within or without, it engages processes beyond the reach of the conscious mind and is therefore transcendent with respect to waking consciousness.

In 2003 and 2004, Todd M. Thrash and Andrew J. Elliot conducted a number of studies on inspiration. In the first study, they discovered that (a) inspiration's motivation is intrinsic, not extrinsic; approach-centered around positive affect, not avoidance-centered; (b) inspiration correlated positively with openness to experience in such a way that it appeared not only to co-vary with inspiration, but facilitate it; (c) inspiration is strongly related to work mastery and absorption which represent a transcendence of constraints in an individual's thought patterns and behavior. Both work mastery and absorption appeared as consequences suggesting inspiration's positive effect on motivation and focus. Though inspiration is evoked, it is not a passive phenomenon, but favors those with a prepared mind; (d) inspiration correlated positively with sense of competence, self-esteem, optimism and importantly, creativity, all of which emerged as consequences; (e) because self-determinism also emerged as a consequence of inspiration, the investigators suggested that "the self cannot take credit for inspiration: the self is discovered, not asserted" (Todd M. Thrash and Andrew J. Elliot, 2003: 886).

In the second study, Thrash and Elliot suggested that inspiration involves a juxtaposition of two processes (a) being *inspired by* which concerns denial of responsibility for the inspirational influence and (b) being *inspired to*, which influences the motivation to transmit or extend inspirational content toward a motivational object (e.g., self-actualization, creative work). Both processes are similarly described in Judeo-Christian and Muslim theologies as the source of scriptural revelation and transmission, respectively. The investigators suggested that the 'by' component of inspiration is triggered by illumination rather than reward salience. Therefore, inspiration is experienced as both transcendent and unwilling. Approach temperament, an ancient appetitive system involving sensitivity, reactivity and behavioral disposition toward positive/desirable stimuli, predicted motivational strength and appears to play an important role in the 'to' component, or transmission. Sometimes, transmission is automatic (as in spontaneous creative or spiritual expression); other times, it is more controlled,

for example, in translating inspirational content into a creative/spiritual work, a goal that fulfils man's higher longing to transcend the sense of self or existent knowledge state.

Search for Freedom

Rollo May, in *The Courage to Create*, declared "Creativity is a yearning for immortality" (Rollo May, 1975: 31). This idea connects creativity with man's deep spiritual longing to transcend SOD, to find meaning. In 2003, Swami Shantananda, in *The Splendor of Recognition*, a treatise on the Kāshmir Śhaivite text *Pratybhijñā-hṛdayam*, described the three psychological veils that limit perceptions of reality. They are the senses of imperfection (*ānava-mala*), separateness (*māyīya-mala*) and doership (*kārma-mala*). The sense of imperfection perceives SOD as a limitation of human will; that is, humans feel powerless to eradicate SOD. The pain of imperfection instills the longing to find perfect joy. Separateness discerns differences such as noise versus information, one idea exceeds another, and life is distinct from death. The pain of separateness creates a longing for union, for wholeness. Doership supports the belief that an action's effects are caused solely by the one performing the action. Doership tends to ignore the complex chain of macro/micro causality that determines even the smallest, most subtle action. The pain of doership creates a longing for surrender to something greater than the self. All of the veils both bind and motivate the individual to evolve. Why some individuals buckle under these existential constraints while others transcend remains an open question. Transcendence of the veils is said to result in liberation (*moksha*), or freedom.

Similar constructs are found in many spiritual paths, for example, Christians and Muslims claim that acts of divine grace bring god-men into the world and perfection to man in an afterlife; divine love overcomes the separation between both man and man, and man and God. Furthermore, actions accepted as offerings to the divine eventually release man from his ego. Creativity addresses these veils as well. It dissolves the sense of imperfection by inspiring artists to seek aesthetic perfection and scientists/mathematicians to aspire to elegance and universality. Overcoming separateness lies in the nature of creative synthesis. Openness to experience, sensitivity, absorption, and self-other unitive experiences alleviate the sense of separation. The creative individual may feel that he is not the actual creator, or doer of the creative work or expression. Dispassion and inspiration help allay the sense of doership. Creativity finds innovative ways to transcend SOD. If one veil is too thick, however, creativity may lead to unalterable destruction.

While the creative artist delimits himself by deepening his intuition and devotion to art, the creative scientist transcends through a process akin to negative theology, the practice of intellectually negating phenomena while seeking absolute truth. In 1935, Karl Popper asserted that hypotheses and theories are scientific only if they are falsifiable. His astute assertion gave science extraordinary explanatory power. A similar assertion rests in the Vedantin practice of 'not this, not this' (*neti-neti*) based on a theology that negates all phenomena as incomplete, or false, until Truth is revealed. The practice is also called the yoga of knowledge (*jñāna yoga*) and is considered the most challenging of all yogic practices because it

requires a high level of discipline, persistence, strong observational and discriminatory powers, objectivity, and the guidance of a qualified teacher. Science exemplifies these same attributes with guidance proffered by the scientific method and peer-derived feedback. Most scientists tend to reject the notion of God and the existence of transcendent phenomena as unfalsifiable. Yet, this does not obstruct the harnessing of scientific breakthroughs and innovative technologies to creatively draw what was once deemed transcendent into realm of falsification. In this respect, science brings us closer to truth, fosters humility and affords a sense of liberating awe at the deeper mysteries of existence.

Creative and Spiritual Contemplation

Horan's concept of intention as the basis for creativity seems insufficient to produce creative works that also require talent and intelligence. He suggested, however, that the root of creativity (which he calls the vacuous state) contains powerful unconscious intentions, or subliminal attentional flows, that also nourish intelligence. These deeper intentions produce intelligent creative works and expressions. Willis Harman and Howard Rheingold in *Higher Creativity: Liberating the Unconscious for Breakthrough Insights* suggested that, the unconscious mind can be yoked willfully through imagery, affirmation, meditation, etc., to make creative choices. In 2000, Tobin Hart suggested that a special internal mind-set is required for courting creative inspiration. It involves focus, trust, letting go, listening and embodiment. *Focus* is a deliberate attempt to use prayer, meditation, concentration, etc., to ask specific questions or direct attention more fully on some phenomenon. Whereas the religious person focuses through communion, liturgy, or a common language, the artist focuses first by preparing his environmental and psychological space then directing energy toward an artistic undertaking. The scientist focuses by reviewing data, finding a problem and creating a hypothesis. During focus, the 'self' reaches out to 'other.' *Trust* implies faith in "a nonrational, postreflective way of knowing" (Tobin Hart, 2000: 47) which elicits detachment from preconceived assumptions and provides suspension of disbelief. Whereas the scientist and artist trust in their gut instincts, the religious person trusts in God or some ultimate reality. Trust builds a bridge between 'self' and 'other.' *Letting go* is an act of volition leading to surrender which is a serious challenge to those who cling strongly to assumptions. Letting go is an extraordinary intention. It demands dispassion and openness, thereby making the mind fertile soil for cultivating new ideas. Artists and spiritual individuals recognize its importance in developing greater sympathy with objects of attention. William Butler Yeats in his poem *Among Schoolchildren* captured the epistemological impact of the artist's letting go, "O body swayed to music, O brightening glance, How can we know the dancer from the dance?" (William Butler Yeats, 1997: 219). Scientists often let go when the solution to a problem appears futile. For example, mathematician Henri Poincaré's discovery, in 1908, of a class of Fuschian functions arrived unexpectedly from what he called the 'principle of forgetting' (Henri Poincaré, 1952: 53). *Listening* allows insight to manifest. It ensures that subtle concepts or cues are not

overlooked. The spiritual person listens for revelation, the artist for inspiration, and the scientist for solutions. *Embodiment* is the transmission of an idea into form, such as a painting, novel, movement, invention, mathematical equation, and so forth. The entire process, from focus to embodiment, demonstrates an attentional rhythm – first contraction, then expansion, and contraction again – much like breathing. The rhythmic process contains a dynamic interaction between transcendence and manifestation, found equally in both creativity and spirituality, but to different ends.

Horan, in 2009, suggested a similar process for engaging the unconscious mind in creative work which he called *creative contemplation*. Creative contemplation is based on a very ancient yogic, or spiritual, meditation practice (*samyama*) developed by Patañjali in the second century AD. It was designed to intentionally induce supranormal powers in the practitioner, of which extraordinary creativity was one. Lynne McTaggart, in *The Intention Experiment* cited a body of empirical evidence supporting the power of intention to alter physical reality at a distance. Horan proposed that the same intentional process via brain plasticity enhances creativity. Creative and spiritual contemplation (or prayer) are similar because they enlist the same attentional mechanisms, one directed toward creative endeavor, the other toward solving existential dilemmas and seeking new ways to transmit old wisdom and meaning to new generations.

A Dynamic Relationship

Because the relationship between creativity and spirituality is both complex and relatively unexplored, a more general theoretical direction is proposed in order to facilitate empirical studies. In 1995, Franklin Merrill-Wolf suggested that an inverse relationship exists between appearances and transcendent Reality. Inverse relationships occur as one variable increases, the other decreases, like a see-saw. Merrill-Wolf indicated that the more an individual gets caught in what appears to be real (e.g., repeated thoughts, facts, assumptions) the less that individual is able to experience more sublime truths (e.g., pure awareness). Imants Barušs, in 2007, converted this profound concept into a simple equation. To better comprehend the relationship between creativity and spirituality, Barušs' equation has been modified (and generalized) as follows:

$$T = 1/I \quad [1]$$

whereby, 'T' is *transcendence* in the Emmanuel Kant sense of knowledge about how one experiences or constitutes objects as objects, a sublime witnessing state that lies beyond the immediate grasp of the intellect. Transcendence is knowledge of what constitutes knowing (i.e., Knowledge). It lies at the foundation of all perceived phenomena. More immediately, Knowledge also includes the infinitude of unrealized informational possibilities. 'I' represents *information*, recognizable pattern(s) that may or may not embody a message (e.g., clear versus ambiguous patterns) and which influences the formation and transformation of other patterns. Implied in the concept of information are partial differentiation and integration of patterns, partial in the sense that absolute differentiation equates to pure randomness (e.g., noise, nonsense) while

absolute integration describes a singularity (e.g., unitive experiences) ... two transcendent poles of the spectrum of knowledge. For example, in cosmology, the cosmic energy flux (and therefore information) appears as absolute transcendence in a singularity (i.e., the source of immense gravitational, or integrative, forces within massive black holes) as well as 'dark energy' which is theoretically attributed to the potentially limitless expansion, and differentiation, of the universe. In either case, $I = 0$ or ∞ (here both 0 and ∞ are described as informational empty sets, the difference being that 0 results from a theoretically infinite gravitational contraction of the universe while ∞ results from the converse, an infinite anti-gravitational repulsion and expansion caused by 'dark energy'). Equation [1] applies only between these extremes (i.e., $0 \gg T, I \ll \infty$); that is, as information approaches zero, transcendence approaches infinity.

In the human psyche, eqn [1] suggests that as information (e.g., schemas, memes, rules, laws, and paradigms) increases, Knowledge decreases; that is, when the mind clings to partial information (e.g., pet theories, strongly held opinions) it becomes crystallized and shallow, not transcendent. At the center of the information spectrum are stable patterns such as well-proven facts, inviolable laws, nature's constants and the concept of reality. Domain knowledge is crucial for both creativity and spiritual growth; however, if such knowledge becomes dogmatic or inflexible, both creativity and spirituality are stunted. In 2004, Dean Keith Simonton suggested that creative incubation involves a quasi-random, combinatorial process. In this respect, randomness expresses informational divergence (transcendence via the randomness pole) and harbors the potential for originality while combinations allow novel information convergences. Unique combinations developed during incubation may lead to insight, a phenomenon that approaches the singularity pole. The new information 'fits perfectly' (eureka!), coalescing with the existent informational field and with a great sense of certainty. Insights often stimulate further incubation. Equation [1] also suggests that information combinations which follow established paths (e.g., that lack transcendence) are not creative.

Spiritual traditions that embody a negative theology cut at the root of cognition and induce inspiration by overcoming the tendency to describe or name things. For example, the ninth century abbot Erigena declared that God is beyond all description and therefore the negative (herein inverse) of all that is perceived. Negative theology resembles the random, or divergent, pole of transcendence by negating information. Alternatively, other traditions, such as pantheism, sanction the singularity, or convergent, pole via a positive theology that condones one-pointed focus on a divine being, or essence, permeating everything. Both approaches challenge the mind to transcend itself. Adverse reactive tendencies like clinging to religious dogma obstruct the search for the sacred. The mathematical inverse of eqn [1] also applies:

$$I = 1/T \quad [2]$$

whereby an increase in transcendence (i.e., Knowledge) decreases information. For example, Albert Einstein's general theory of relativity unified space-time and gravity; but, when first published, found only a few physicists that could comprehend it. The theory's level of transcendence, or abstraction,

exceeded the capacity of those steeped in existing physical paradigms to grasp its meaning. The same phenomenon appears often in creative works or expressions that reject entrenched paradigms. Similarly, mystics describe unitary states as ineffable, as abstract to the point that language cannot capture them, whereby approximations such as symbols and metaphors serve as communication vehicles. The following equation mathematically emerges from either [1] or [2]:

$$TI = 1 \quad [3]$$

Here, the dynamic interplay of transcendence and information is synergized. Creativity was described by Todd I. Lubart, in 2001, as a dynamic, often recursive or cyclic, process involving many complex subprocesses gravitating around what Graham Wallas, in 1926, described as the four phase model of creative process involving preparation, incubation, illumination, and verification. Whereas preparation and verification phases center on information gathering and evaluation of the known, incubation and illumination focus on transcendent exploration and discovery of the unknown through novel associations. Spiritual process often follows a similar dynamic. Its preparatory phase, comprised of scriptural study and practice, is followed by inner work (spiritual incubation) and occasionally by an inspiring experience of unity, a deity, or communion which is then evaluated and implemented into everyday life. The '1' in the equation suggests a dynamic perfection, or balance that, depending on the nature and scope of the variables, manifests as anything from a new flower arrangement or momentary feeling of spiritual connectedness to powerful psychological encounters like *flow* (identified by Mihaly Csikszentmihalyi in 1996), *living in the Now* (described by Eckhart Tolle in 1999) and the *play of Consciousness* (*chidvilas*, illuminated by Swami Muktananda in 1978). If T or I , in eqn [3], ever reached 0 or ∞ , then $T = I$, an ineffable state in which all information is absolutely transcendent, a state described in many mystical accounts of an ultimate reality. Figure 1 is a four, spatial dimensional representation of eqn [3] in relation to its limits (i.e., 0 and ∞). The graphically-depicted fourth

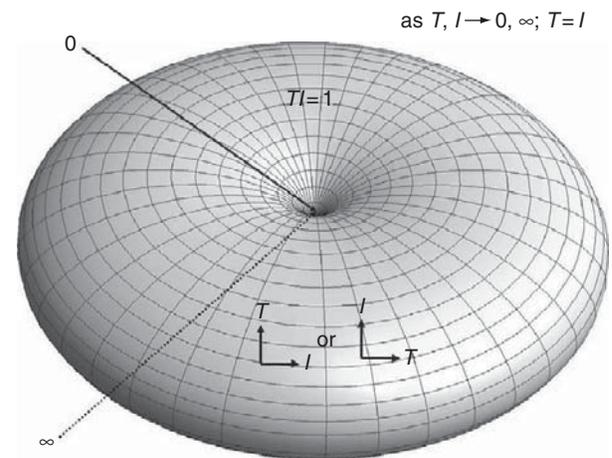

Figure 1 Movement from 0 to ∞ , and reverse, occur over the surface of the *sphorus* (sphere-torus). Simultaneously, both T and I , in four dimensional space, inverse their surface vector directions. The *sphorus*' surface represents all solutions except $T = I$ which appears in the singularity (i.e., the empty set).

dimension (embodied in an object herein called the *sphorus*) allows both *T* and *I* to have simultaneously inverted spatial directions thereby denoting the ultimately transcendent nature of all information as well as the information-potential inherent in transcendent states.

The 'TI' model furthermore serves the purpose of differentiating the complex relationships between science, art, religion and mysticism, provided that creativity is assumed to incline toward values incumbent in information (i.e., knowledge), objectivity, and its expression while spirituality is assumed to lean toward more transcendent values like Knowledge, subjectivity, and its expression. In 2005, Jan Tønnesvang defined self-actualization in terms of a bipolar self wherein one pole (sense of self) carries the properties of agency, assertion, and creativity while the second pole (sense of other) is attuned, or influenced, by ideals, values and sociality in the greater context of communion with something larger than the self. The interplay of poles, one creative, the other more spiritual, can result in a joyous dialectic that reinforces both. Creativity and spirituality interactions with the knowledge-objectivity/knowledge-subjectivity variables form a 'TI' matrix supporting the domains of science, art, religion and mysticism.

Figure 2 indicates that science and religion may differ in their approaches to knowledge, conflicting over the nature of objectivity by juxtaposing science's faith in evidence and nature's empirically-derived laws with religion's faith in revelation-derived scripture and religious dogma. At the same time, they both share a search for meaning and/or Truth. Science and art are related through creativity such that art inspires science and science informs art. Leonard Shlain, in 1991, discussed this accord in *Art & Physics*. He suggested that art has always foreshadowed breakthroughs in physics. To see how science informs art, one need only look at the technologies employed in modern film productions. The largest domain contrast lies between science and mysticism. Deeper investigations into cosmology and quantum physics have, however, provoked near-mystical awe (sometimes repression) in many scientists. The model predicts that science will eventually induce semi-mystical states, perhaps as treatment for pathological conditions like depression and anxiety. For example, Michael A. Persinger, in 1983, used transcranial stimulation of the temporal lobes to actuate altered states. Art and religion have had a close relationship for centuries with religious art dominant until the Renaissance and diminishing later with scientific advancement. Art's sublimity uplifts both heart and mind

while the sacred inspires art. Mysticism lies at the core of most religious traditions. There are Christian mystics, Sufis in Islam, Kabbalists in Judaism, Hindu yogis and Zen Buddhist practitioners. Many of the great religious transformers were mystics. Mysticism plays an important role in art. Zen mysticism, for example, finds expression in painting, calligraphy, tea ceremony, gardening, etc. Though differentially weighted, creativity and spirituality can be found in all four domains in accordance with an individual's propensities and his culture's relationship to both transcendence and information. Using the 'TI' model, empirical investigations of a creativity-spirituality connection may be facilitated through psychometric designs that bridge these knowledge domains and evaluate potential cognitive, social, affective influences on that connection as well as via experiments which explore the roles of arousal, attention, insight (including revelation) and other neuropsychological markers related to transcendence, recognition, and integration, of new information.

Conclusion

The relationship between creativity and spirituality is ancient. Empirical investigations into this relationship have been stunted by lack of a clear definition for spirituality as well as by the complexity in measuring both constructs. In order to provide a scientific direction in this regard, an inverse relationship, based on the concepts of transcendence and information, is suggested as a platform for gauging and extracting both neurological and psychological similarities and mechanisms driving both creativity and spirituality. Transcendence is depicted as the unique variable underlying the ability to create and the capacity to experience the sacred. The level of transcendence fluctuates with the mind's attachment to information, fixed notions, paradigms, etc. Various psychological phenomena are found to illustrate transcendence in both creative and spiritual individuals including openness to experience, sensitivity, absorption, synesthesia, dispassion, transluminance, unitive experiences of self and other, mysticism, moments of inspiration and psychological freedom. Further similarities exist in the nature of creative and spiritual contemplation, processes that involve focus, trust, letting go, listening and embodiment.

Glossary

Game analysis Game analysis software allows study of the individual tactical behavior of the players (e.g., feints in one-on-one-situations), the tactical interactions of a group of players (e.g., specific combinations in offensive play), and the general game strategy of a team (e.g., playing more defensively).

Game sport Team sports such as soccer, basketball, volleyball, and racket sports including tennis, table tennis, and badminton.

Game test situations Game test situations are simple game forms with clearly defined game ideas, fixed numbers of players, as well as defined rules and environmental conditions. The fundamental idea is basic constellations with clearly allocated roles in order to create recurring and consistent conditions with many repetitions for the participants. In order to analyze the creative actions, a video of the recorded behavior is subsequently rated with regard to specific concepts by several independent experts.

Inattention blindness Failure to detect an unexpected object if attention is diverted to another task or object.

Neural networks A neural network is a type of computer algorithm which consists of a grid or matrix of neurons.

The dimension of this neuron matrix determines the dimension of the network. Neurons are trained with data and so build clusters of similar input data, without needing any additional information. These clusters define types of input data and thereby help to recognize and identify test data after the training phase. A given test input is recognized by the net as corresponding to the cluster to which it is most similar and is therefore identified by the type (e.g., name, specification) of that cluster.

Regulatory focus theory Two modes of self-regulation are proposed in this theory: a focus on accomplishments and aspirations is labeled as a promotion focus to regulate pleasure, while a focus on safety and responsibilities is called a prevention focus to avoid suffering.

Tactical creativity (= divergent thinking ability) Tactical creativity is defined at the behavioral level as the unusualness, innovativeness, statistical rareness, or even uniqueness of solutions to a related sport situation in team ball sports.

Tactical intelligence (= convergent thinking ability) Tactical intelligence refers at the behavioral level to the ability to find the ideal solution to a given problem in a specific situation in team ball sports.

What Is Creativity in Sports?

Definitions

Sports is a worthwhile field to study behavior in a complex context. In particular, complex situations enable creative performance to be analyzed in an ecologically valid way. The distinction between expert decision making and creativity in sports are closely linked to the theoretical distinction between 'divergent thinking' and 'convergent thinking,' concepts which were first proposed and defined by Joy P. Guilford and first transferred to the world of sport by Klaus Roth.

Convergent thinking, or tactical intelligence, refers at the behavioral level to the ability to find the ideal solution to a given problem in a specific situation in sports. For example, basketball star Dirk Nowitzki may anticipate future moves of an opposing offensive player and step in front of him provoking an offensive foul. Divergent thinking or tactical creativity is defined at the behavioral level as unusualness, innovativeness, statistical rareness, or even uniqueness of solutions to a related sport situation. Therefore, tactical creativity can be regarded as a variety of rare and flexible decisions used in different kinds of situations. Basketball star Earvin 'Magic' Johnson became famous for his so-called 'no-look-passes,' seeming to be able to take in all relevant stimuli of a situation, and use this information to fool his opponents by looking in the direction of the most obviously free teammate while passing the ball to another player.

Practical Utility

Sport science literature frequently suggests that both game intelligence and tactical creativity are important for successful athletes in different kinds of sports. In order to generate decision possibilities and seek original solutions players must be able to perceive all important information from their environments (positions of team mates and opponents, players emerging unexpectedly, etc.) and consider this information when generating an action plan. Tactical creativity is increasingly significant for complex sport games because coaches are able to collect more information about their opponents. For example, with game observation and game analysis it is possible to study the individual tactical behavior of the players (e.g., tendency to move left or right in one-on-one situations), the tactical interactions of a group of players (specific combinations in offensive play), and the general strategy of a team (e.g., fast breaking at every opportunity). As [Table 1](#) indicates, several famous soccer coaches in Germany pointed to a lack of creative players in all leagues. With the development of versatile, and at times extraordinary solutions (tactical creativity), a significant and domain-relevant ability in sports games is recognized.

Evaluation: Game Test Situations

Different kinds of instruments have been developed to evaluate an athlete's tactical decision making skill. Currently, only a

few sport-specific tactical creativity tasks have been constructed and tested for objectivity, reliability, and validity (see Table 2) and these include game test situations which act as a type of compromise between standardized tests and game observation methods discussed below. Game test situations are simple game forms with clearly defined game ideas, fixed numbers of players, as well as defined rules and environmental conditions. The athlete's creative behavior is assessed without trying to standardize the ball paths and actions of team mates and opponents; hence, the fundamental idea is basic constellations with clearly allocated roles in order to create recurring and consistent conditions with many repetitions for the participants. In order to analyze the creative actions, a video of the recorded behavior is subsequently rated with regard to specific concepts by several independent experts.

Evaluation: Standardized Tests

Tactical creativity tasks are relatively highly standardized. Athletes view brief video sequences of a sports game (e.g., basketball, soccer) in which attacking players play against defending players. At the end of the video clip, the final image appears frozen with one player in possession of the ball. The participant takes over the role of the ball holder in the video clip, identifying all opportunities that might possibly lead to a goal/basket. The motor executions (e.g., pass with the non-dominant hand/foot, indirect pass) should also be mentioned. Athlete's answers were noted on a specially designed sheet that

Table 1 Statements of soccer coaches from the National Team and the '1. Bundesliga' in Germany

- "Imagination and creativity should be left to the Brasilians" (Franz Beckenbauer)
- "The midfield is not creative enough. We no longer have a Häbler or a Littbarski. Certain things have been neglected that need to be put right" (Jürgen Klinsmann, former German National Team Coach)
- "Technically and tactically, other countries are far ahead of us. That is why in many clubs the creative player is a foreigner" (Christoph Daum, Fenerbahçe Istanbul)
- "Whenever the Germans want to be creative they can't manage it. They are unable to control the game" (Jürgen Klopp, Borussia Dortmund)

Table 2 Description of sport-specific divergent thinking tests which evaluate tactical creativity in sport

Label	Task	Authors
Game test situation	This instrument contains a context-dependent real world setting that can directly provoke tactical tasks in ecologically valid situations. Participants' tactical behaviour is recorded on videotape and their tactical decisions are analyzed by expert coders using a subsequent concept-oriented expert rating system (criteria: originality, flexibility).	Memmert (2006, 2007, in press); Memmert and Roth (2007)
Video creativity task	In this decision task, participants watch sport-specific videos. The image is frozen after 1 min. The participants have to imagine themselves as the acting player and name all opportunities that might possibly lead to a goal. The answers are evaluated according the criteria of originality, flexibility, and fluency.	Johnson and Raab (2003); Memmert (in press)

Source: Grunz A, Memmert D, and Perl J (2009) Analysis and simulation of actions in games by means of special self-organizing maps. *International Journal of Computer Science in Sport* 8: 22–36.

contained all appropriate decisions. The same observation criteria of originality, flexibility, and fluency were used for the athlete's performance as in the usual divergent thinking tasks in psychology; originality of the proposed solutions were rated by experts. For flexibility, all possible tactical decisions in each situation were categorized into ten different kinds of solution options (e.g., perform a one-on-one action, no-look-pass, and pass with a feint). The number of appropriate answers given by a subject for each video scene was used to measure fluency.

Analysis: Game Observation

Technological advancements allow the automatic recording of position data of players and the ball enabling reconstruction of tactical patterns. Furthermore, it is now possible to classify action processes in soccer by means of neural networks and to check the identified process types with regard to their effectiveness. In particular, activities can be recognized which indicate creativity, i.e., activities which are original as well as adequate solutions to the situation. For example, in soccer, a rare combination of several passes which leads to a goal.

A central aspect of game analysis is to quantify the complex qualitative information of a game such as soccer or basketball. The focus of such quantification is on the frequency and success of specific actions such as passes or moves. Once the position-oriented tactical patterns can be recognized by means of a correspondingly trained neural network, it is no problem to automatically count transitions between such patterns with respect to the corresponding actions. This leads to a matrix of transition probabilities as is shown in Figure 1, matrix top-right. Moreover, if the corresponding trajectory network is calibrated to record the success of the represented process, a second matrix can be generated representing the success of those transitions, as is shown in Figure 1, matrix bottom-right. The probabilities of transitions and their success help analyze games and the information-theoretical relevance of actions can be estimated using their time-dependent frequency profiles. Under the assumption that a creative action is rare as well as adequate, the information-theoretic relevance, together with the semantic evaluation of adequacy, enables measuring and analyzing the creativity of actions in an ecologically valid setting. For example, Memmert and Perl showed that out of 5903 complex real-life behaviors in team sports only 1 per cent of the evaluated tactical decisions of all participants was a pass over the defenders to the opposite side (= loop shot).

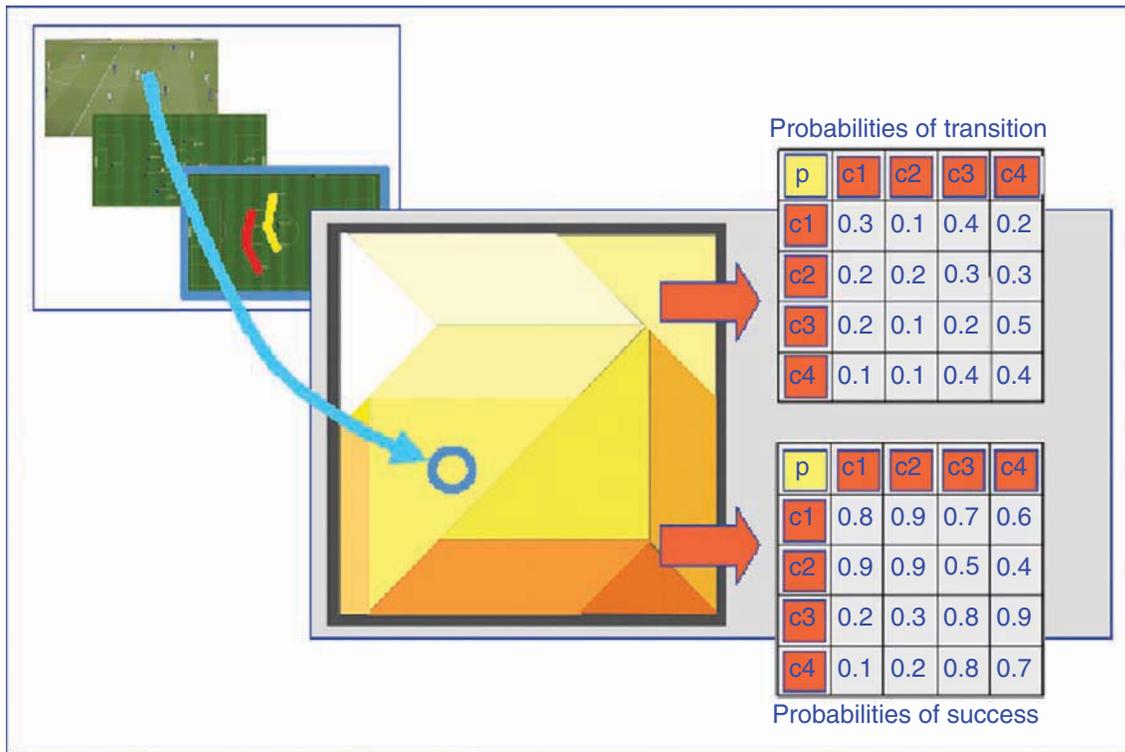

Figure 1 Process analysis resulting in statistic contributions. Grunz A, Memmert D, and Perl J (2009) Analysis and simulation of actions in games by means of special self-organizing maps. *International Journal of Computer Science in Sport* 8: 22–36.

Simulation

An advanced application of neural networks is the simulation of tactical behavior, creative actions, and dynamic learning in games. The current action such as tactical decisions in the game process or movement behaviors of the athletes is tested on the network, activating the corresponding neuron, which then returns information in different semantic categories such as type of activity, degree of creativity, probability of success, or probability of transition to other activities. The goal is to replace the current activity with a simulated one, which when activated in a game situation could be more creative or more successful. More specifically, the resulting simulated process could improve the team’s tactical behavior. Mapped to a network, this means that neurons should have the ability to represent not only frequent but also rare actions. If such a net is calibrated with respect to success or adequacy, then the time series of a process is mapped to a trajectory, where the neurons can be recognized to correspond to creative actions. For example new specific tactical combinations in soccer could be theoretically or practically developed and directly tested in a neural network simulation.

Factors Influencing Tactical Creativity

A theoretical framework is suggested in the next two main sections that contain several individual studies and experiments, which can be seen as the basis for the development of tactical creativity in sports. **Figure 2** outlines a theoretical framework resulting from extensive research and can be

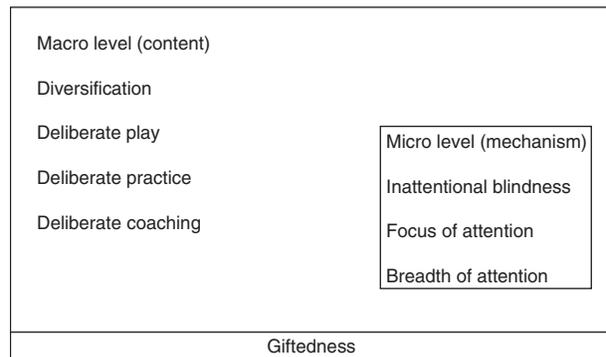

Figure 2 Theoretical framework for 3x4 environment-training-model of the development of tactical creativity.

seen as the basis for the development of tactical creativity. It distinguishes between a micro level (process) and a macro level (content). The micro level examines the mechanism and psychological processes in the respective training situation (micro rules) that lead to the generation of creative ideas. The macro level examines the environmental conditions that can be steered by teachers and coaches (macro rules).

On a micro level, there are three mechanisms that facilitate unexpected and original solutions:

1. by using fewer instructional options to focus attention in team ball sports (inattentional blindness, micro rule 1), and
2. by giving no external attention cues which point out ‘information rich areas’, the attention is not restricted and thereby facilitate creative behavior (micro rule 2);

3. with a large breadth of attention (micro rule 3) unexpected and potentially better alternative solutions can be perceived, used, and hence learned.

In addition, the genetic dispositions of athletes are important. While to our knowledge there exists only preliminary studies linking talent development (motor skill giftedness) and tactical creativity in sport, early evidence suggests cognitive giftedness is a valid predictor of faster development of creative solutions in sport (see [Figure 2](#), bottom).

On a macro level, environmental conditions are created and curriculum designs have to be implemented that correspond to the criteria of

1. diversification (macro rule 1),
2. deliberate play (macro rule 2),
3. deliberate practice (macro rule 3), and
4. deliberate coaching (macro rule 4).

Inattentive Blindness

As described above, tactical creativity is always associated with the ability to generate unexpected and unusual solutions in sports. For this reason, the inattentive blindness paradigm (if attention is diverted to another object, observers sometimes fail to notice an unexpected object, even if it is right in front of them) is ideal for the research of creative processes in sports, since attention performances are associated with the discovery of unexpected objects. Developmental research by Memmert makes a direct link between inattentive blindness, expertise, and creativity. Sport-specific trained adolescents with the ability to notice the free player could describe more original solutions in the sport-specific situation than the 13-year-olds who were 'blind' to the free team mate. At this point, it should be mentioned that the effect reported for the domain of sports was also found in the area of general psychology. Here, the untrained adolescents, who achieved better performances in a general inattentive blindness task, also fared better in the general creativity test in contrast to the participants who could not describe the unexpected object.

The above findings highlight the fact that the inattentive blindness paradigm also appears to play a considerable role in competitive sports. Team players often fail to find the optimal tactical solution to a situation because the coach narrows their focus of attention by giving restrictive instructions. Team members could, however, capture the attention of other team mates by waving their hands as important meaningful exogenous stimuli. This led to a major reduction in inattentive blindness. These findings show that current theories in the field of neuropsychology also have explanatory potential in more complex contexts. Motivational factors therefore control the direction of attention and influence information processing before players consciously perceive specific input.

Focus of Attention

Following the inattentive blindness paradigm, a series of experiments on attention focusing analyzed the influence of special kinds of instruction on tactical decision making in team ball sports. Players do not find creative tactical solutions if they receive attention-directed instructions, because of their reduced

attention focus. More complex and sport-related problems were constructed for a series of cumulative labor experiments. In a sport specific tactical decision making test, adolescents were given the primary task of naming the position of their direct opponent at the end of the trial (attention-demanding task), while also finding a totally open player (secondary decision-making task) that would most likely lead to a goal. Of the participants, 45% failed to notice the open team member. This result was confirmed in other sport-specific situations with adults. Completely open team members were missed by approximately 40% of male basketball players with more than ten years of competitive experience. Even in more realistic contexts with motor responses as well as a primary task closer to the field (triple selection task), this effect was unchanged. That means that instructions that give a narrow focus, for example, just mark a player, lead to players not seeing as many creative opportunities as when instructions are less specific.

Breadth of Attention

Breadth of attention is the term used to refer to the number and range of stimuli that a subject attends to at any one time. Results from attention-narrowing environment stimulation experiments indicated that with a narrow breadth of attention, not all stimuli and information that could lead to original and possibly unique solutions in a certain situation can be perceived. A wide breadth of attention, on the other hand, makes it possible to associate different stimuli that may initially appear to be irrelevant. Colin Martindale (1981, p. 372) explained this fact as follows:

The more elements that a person can focus on simultaneously, the more likely it is that a creative idea will result. [...] Thus, with three elements [...] there are three potential relationships [...] to be discovered. With four elements, there are six potential relationships, and so on.

Experiments in sports science supported the view that fewer instructions by the coaches during game play lead to a wide breadth of attention and therefore facilitated greater improvements in tactical creativity. Participants were confronted with exactly the same tasks as above (focus of attention) while one group received more, and the other group fewer tactical instructions (narrow/broad breadth of attention), in order to investigate the influence of these instructions on the tactical decision. The results indicated that too specific instructions prior to the tactical decision lead to inferior tactical decisions compared to fewer instructions.

Giftedness

Research also suggests that cognitively gifted persons (IQ > 130) seems to improve their tactical creativity more quickly than individuals with average IQs (IQ = 100). In contrast to a gifted control group (gifted children without a sport-relevant intervention) and a nongifted sport-relevant intervention group, the sport-specific creative performance of the gifted children significantly improved after a six month training program of tactical creativity. Here again, the influence of attention performance and inattentive blindness for the development of creativity was demonstrated.

Factors Supporting Tactical Creativity

Diversification

A longitudinal research talent program was designed to investigate the efficacy of various training approaches in team ball sports for the development of tactical creativity. The main assumption was that the perception of many different sport game situations and the acting in these situations has a positive influence on the development of tactical creativity. A total of 135 young athletes took part in a 15-month, field-based study, where they participated in either nonspecific treatment groups (tactical training with hand, foot, and implements); a handball group (tactical training only with the hand); a soccer group (tactical training only with the foot); a field hockey group (tactical training only with implements), and a control group (no training at all). General and specific sport-oriented tactical creativity as dependent variables were measured with game-test-situations. The analysis of treatment-related effects showed that the areas in which the groups were trained (e.g., soccer, handball, hockey), were precisely the areas in which they showed significant improvements. This could be interpreted as evidence for specific training effects; however, nonspecific experiences seem to be a promising alternative to specific treatments. Unlike motor competencies, it seems possible to train tactical creativity independently from motor skills. In summary, nonspecific and specific concepts are on a similar level in terms of tactical creativity development. In fact the nonspecific approaches can even prove to be more workable in the long term.

Deliberate Practice

The term 'deliberate practice' refers to targeted and task-centered training programs based on instructions. Studies of eminent athletes' early development indicates that deliberate environmental influences and organizational conditions benefit the generation of original thinking in sport. Trainers from different types of team sports selected the most creative and the least creative players from their teams. Creative, exceptional athletes in basketball, soccer, handball, and hockey trained significantly longer and more purposefully in their main sport before they were 14 than less creative top athletes ('deliberate practice'). In this case, specific experiences over a long time (ten plus years) are necessary for the attainment of expertise.

Deliberate Play

The term 'deliberate play' refers to noninstructed involvement in play-oriented and at first sight unstructured situations in sport games. In the past, children used to play in fields and roads without coaches and systematic training schedules. Today in Western Europe and North America, they miss the natural experience of playing in the streets for their creative development. As Jean Côté suggested, the sampling years (ages 7–12) are characterized by a high frequency of deliberate play. Self-determination theory and Vallerand's hierarchical model of sport motivation both support the notion that early deliberate play will have a positive effect on intrinsic motivation over time. It also showed that highly creative athletes played far more often in their early youth (up to 14 years of age) and

hence more intensely in many relatively unstructured (complex) team ball sports situations ('deliberate play') without guidance than less creative team players. The results suggested that unstructured play-like involvement plays a crucial role in the development of creative behavior in basketball, handball, field hockey, and soccer. At the same time, current theoretical approaches and empirical research regarding the development of creativity support this view that nonspecific experience over time, such as unstructured play, is an ideal medium for the development of divergent thinking.

The reported evidence provides a basis for the convergence of two prevalent research programs (expertise research, creativity research) that have not yet been discussed in the same context. Both results suggest that practice experiences and early play significantly influence the development of creativity. In this case, specific experiences over a long time (ten year rule) are necessary for the attainment of expertise. At the same time, current theoretical approaches and empirical research regarding the development of creativity support the view that diversified and even nonspecific experience, such as unstructured play, over time is an ideal medium for the development of creative thinking. It is possible that sports science in ecological settings can contribute to the further development of expertise models from developmental psychology.

Deliberate Coaching

As stated previously, research demonstrated that simple instructions lead to reduced attention focus and less effective decision making. Research on training examined if these results could be directly translated into practical training concepts. A six-month longitudinal study examined different kinds of instructions by coaches ('deliberate coaching') during training sessions on the development of tactical creativity in team sports. Creative performance was measured by a real-world sport-specific creativity task in which an attention-broadening and an attention-narrowing group of young athletes performed the same kind of exercises. The only difference concerned the role of the trainers who gave the attention-narrowing children explicit tactical instructions and corrections for each game type. In contrast to the teaching models of the attention-broadening program, this training program discouraged the young athletes from learning to direct their attention toward different kinds of stimuli. As a result of this narrow breadth of attention, not all stimuli and information that could lead to original and possibly unique solutions in a game situation could be identified and applied appropriately. In the attention-broadening training group, the coaches only defined the idea and the rules of the games, and no special tactical advice or feedback regarding attention focus was given. As a result, the young athletes learned to have a wide breadth of attention in complex situations which significantly improved their creative performance. Considered together, these findings highlight the opportunity to focusing attention on the coaching process while training creativity in sports. A wide breadth of attention makes it possible to associate different stimuli that may initially appear to be irrelevant. Giving children reduced instructions, offers athletes the possibility to seek out and recognize unexpected and possibly better alternative solutions.

Summary and Future Directions

Summary

In all sports, athletes have to absorb and process substantial amounts of information within a very short time. They have to pay attention to sensory impressions that are at first very new to them and, because of that, are often unexpected. This raises the question of how athletes can become more proficient at perceiving constant minor and major changes caused by the interaction of their opponents and team members when their attention has only been directed to a few specific aspects of the situation by their coach. Coaches are challenged to find ways of increasing their players' proficiency by identifying tactical solutions; however, it is not possible for any coach to mention all possible solutions for any situation or for the player to remember all of them. Phil Jackson has won more National Basketball Association titles than any other coach by teaching his players the triangle offense where they are trained to improvise and always pass to the open man.

Considered together, the findings discussed earlier highlight the fact that the 3×4 environment-training model can play a useful role in promoting the development of creativity in athletes. Research suggests that keeping conditions playful encourages greater learning for young children in team sport games. In addition, findings suggest that experiencing a number of different sports and games is an ideal medium for players' creative development. Young athletes appear to benefit from the different tactical situations encountered in sports games played during their childhood.

On a practical level, the research presented has implications for the design of tactically oriented training programs and curricula. Environmental conditions can be created and curriculum designs implemented that correspond to the criteria of diversification, deliberate play, and deliberate practice. There are also some methodological principles for training athletes . . . For example, attention focus in team ball sports can be broadened, through lessening specific instruction. With a wider attention focus, unexpected and potentially better alternative solutions can be perceived and executed.

Future Directions

Different types of motivationally oriented theoretical models from social psychology indicate that creative performances can be directly influenced by the simplest of instructions, for instance manipulating emotional states of the subjects. Tory Higgins proposed two modes of self-regulation, in order to regulate pleasure and suffering, that is, to direct behavior towards promotion or prevention targets ('regulatory focus theory'). More specifically, a focus on accomplishments and aspirations is labeled as a promotion focus, and a focus on safety and responsibilities is called a prevention focus. In addition, there is no prior advantage of either motivational orientation in terms of performance. According to this approach, the performance on a given task may depend on the fit between people's regulatory focus (promotion or prevention) and people's chronic regulatory orientation (promotion or prevention). This idea of better performance and a more positive effect via regulatory fit has already received some empirical support in the domain of cognitive tasks and sport-related settings.

Numerous studies show that different cognitive performances can be influenced through motivational states or the 'regulatory focus theory.' For instance, a series of experiments strikingly document that a happy mood can positively influence creative performances, encourage the generation of innovative ideas, and promote the generation of exceptional free associations. At the moment neurocognitive mechanisms underlying the flow experience like happiness or fulfillment are discussed and investigated. Beyond this, Ronald Friedman and Jens Förster presented further experiments that underlined the influence of attitude on achieving positive outcomes (promotion focus) and creative performances. Recent results of studies in sport science suggest that it is worthwhile examining in more detail, in sport-specific settings, the dependent-variable divergent tactical thinking in line with the 'regulatory focus theory.'

Aside from the aforementioned further studies necessary on the link between motivation and creativity, the largest gain in insight is expected in the future exploration and experimental examination of attention theories. Unconscious processes serve as an early selection mechanism, which favors useful or emotionally interesting information for further processing.

Alfred Stieglitz 1864–1946

L K Cartwright, San Francisco, CA, USA

© 2011 Elsevier Inc. All rights reserved.

Introduction

Alfred Stieglitz was the preeminent photographer of the early twentieth century. He took many iconic photographs which are held in high esteem and included in major museum collections world wide. His influence on photography was formidable, transforming it from hobby status to fine art and in that process he mentored many of America's foremost photographers. At the same time, Stieglitz had a remarkable range of talents which went far beyond his acknowledged connoisseurship and reputation as a superb photographer and propagandist for photography as fine art. He was also an educator, an essayist, a key disseminator of esthetic practices, a gallerist, a collector, and a charismatic, if opinionated, raconteur. He established a unique, noncommercial gallery space, '291,' which became the center for launching American Modernism in the USA and for allowing many American artists, poets, and writers to gather, to influence and inspire each other, and to exhibit their work.

Family Background and the Early Years

Born in 1864 in Hoboken, New Jersey, he described himself as an American. The first born child of German Jewish immigrants, he hardly led a typical American life. His father, Edward, was a successful businessman who embraced the arts and conducted a salon in his home where artists, poets, and writers met. The family moved to Manhattan when Stieglitz was seven years old. Conversations about the arts continued in Lake George in upper New York State where the Stieglitzes spent their summers beginning in 1872. These group gatherings and spirited conversation accompanied by good food and wine offered him a template for creative environments. Never a fan of silence, Stieglitz later would voice his own ideas on art with undeniable, and often contradictory, authority.

The presence of twin brothers and three sisters gave the young Stieglitz a ready made group. He apparently envied the twinship of his brothers and some biographers think he was always looking for his twin or soul mate. Perhaps, a parallel story line is that he became especially gifted at getting his mother's attention despite the always present competition of bright and clamorous siblings as well as his not-to-be-overlooked dashing father. Hedwig Stieglitz called her son her 'little Hamlet' – sensitive, theatrical, moody, and hard not to notice. He developed a philanthropic narcissism early on, an unusually skillful way of managing both sibling rivalry and oedipal conflicts. One apocryphal tale finds him offering money and sandwiches to an organ-grinder who appeared many times at the family home during dinner. When asked by Hedwig years later, did he remember the indigent organ-grinder? He replied that of course he did and furthermore, he was not giving to the organ grinder but really giving to himself and he always knew this to be the case.

His father's influence on his development was complex: indisputably, he encouraged his son's creativity and love of the arts. Edward Stieglitz provided the whole family with a rich cultural life. At the same time, Edward Stieglitz was a successful entrepreneur and can be regarded as an early capitalist – he was in the wool business and was so financially successful that he retired at the age of 49. Most problematic for Alfred was his father's attitude toward money. Alfred remembered the constant wrangling and bickering about finance that seemed an everyday occurrence in the Stieglitz household, with his father accusing his mother of being a spendthrift. Alfred swore that money would never mean that much to him. His support of artists in his circle, particularly John Marin, as well as his purchase of so many artists' works, spoke to his generosity.

At the same time, let's not airbrush away his ease in getting others to fund his art enterprises – publications, luncheons, and gallery rent – his friends and wife, Emmeline, not only admired him but often supported him as well. The ambivalent relationship with his father's authority permeates his personality, his art, and close relationships: Alfred was most comfortable with the role of seer and he handled idolatry well. Not so with dissenting opinions where he often dropped people from the circle when their ideas or agendas challenged his. Although never especially interested in politics *per se*, he was a radical dissenter when it came to art. Like many of the creative individuals studied by psychologists, he preferred the new to the old and furthermore had the competency to make the new, to write about the new, and to sell it. Counterbalancing his autocratic style, was his ability to work prodigiously, to be intrinsically motivated, to demonstrate integrity, and to place an immensely high value on creativity. Even if you did not like him, you had to respect Alfred Stieglitz.

Education Abroad

Alfred attended private schools in Manhattan and enrolled at the then new City College. At this point, his father decided that a first-class education for his children could only be obtained in Europe where schooling was broader and more flexible. A surprising amount of anti-Semitism was present at City College which seemed to be the tipping point for Edward Stieglitz's decision to depart. In 1881, the still very successful Edward sold his holdings, and with wife, children, much luggage, and servants returned to Europe where he placed his children in German private schools and began himself to paint and tour the continent accompanied by his wife. During vacations, the family would come together and resume their close connections. This sojourn in Europe was pivotal in permitting Stieglitz to bridge cultures and relocate esthetic forms later in his life.

Alfred would remain in Europe for almost a decade. He, unlike his twin brothers, was not interested in the pure sciences although he studied briefly with Hermann von Helmholtz.

And by chance he took a course on photochemistry in 1883 with Dr Hermann Wilhelm Vogel. This meeting was a turning point for Stieglitz who finally connected with something challenging that was a perfect fit for his interests and personality – photography was new, precise, esthetic, and offered an unlimited experimental possibilities. Soon after, he bought his first camera. The rest is chronicled in the history of photography and in numerous biographical works on Stieglitz's life.

Briefly, he studied with Vogel and proved to be an amazing student: his work entered many competitions and quickly won prizes – over 100 – and recognition for technical and esthetic excellence. In Europe he traveled with friends to Italy, France, and Switzerland and took pictures of street urchins, peasant women, monuments, and the countryside. Self-portraits taken during this period reveal him to be striking and he continued to be visually intriguing throughout his life – an intense gaze, elegant bone structure, tousled, thick hair, a large mustache, and a serious manner. He had romances, loved Wagnerian opera, played cards, and enjoyed all kinds of theater including both Shakespeare and vaudeville. He led a bohemian life and from all accounts had a great time.

Return to the United States: The 1890s

His father who had already returned to the States a few years before began to think, perhaps, he was having too good a time and called him back to the duties/life tasks of a young adult. His younger sister had recently died in childbirth and the family needed to regroup and reestablish family bonds. Coping with the loss, reinforced the seriousness of life: it was time to marry, to settle down, to start a business. And Stieglitz did. In 1893 he married Emmeline Oppenheimer, his best friend's sister, ten years younger than he was. Emmeline admired him greatly but never shared his passion for adventure, art, and new ideas. She enjoyed the conventional life of a wealthy young woman in New York – fine clothes, traveling first class, and a well run bourgeois household. Retrospectively, the marriage was a fatally bad choice. Still it was primarily her wealth that provided Stieglitz with the resources to rent gallery space, to publish magazines, and to entertain poets, artists, and critics in good style. For five years, he followed his father's dictates and operated a printing house – Photochrome Engraving Company – with two partners in New York – and there he learned particular skills in printing which enhanced in his earliest photographic work. It will come as no news that the life of the businessman was 'unsuitable' – too boring, too commercial, and definitely not beautiful.

Camera Clubs and *Camera Notes*: 1890–1903

There were hundreds of camera clubs in the United States at the turn of the century. These were the days before the Polaroid and the digital camera and camera fans needed dark rooms to develop film and places to take portraits and advice on how to use the new and popular technology. Photo-making absorbed Americans from all walks of life. Stieglitz, because of his European education and recognized expertise, seized the leadership of a major camera club in New York, the Society of American Amateur Photographers, and became its president in 1890–1891.

The passion not filled by business found a creative outlet in writing and editing the club's magazine. However, he became increasingly dissatisfied with the stuffiness of the New York camera clubs and in 1897 combined the two largest clubs into the Camera Club of New York and expanded and transformed its publication, *Camera Notes*, into a beautiful magazine, the most significant photographic journal of its time. It was through this journal that his major contribution to photography was realized: he elevated the status of photography and by setting high esthetic standards he argued that photography could be on an equal footing with painting. Pictorial photography (i.e., soft focused, evocative, emotional, and personal), represented the ideal way of working the medium although years later he would change his preference away from the painterly to 'straight' photography.

Stieglitz's grand vision for photography absorbed him completely. He said on more than one occasion that he had all but killed himself for photography. Stieglitz wrote for *Camera Notes*, gave lectures and demonstrations at the Club, and managed the Club's exhibitions. Although being the voice for the advancement of photography was incredibly consuming, he found time to take elegant, heartbreakingly beautiful images of New York. In 1901–1902 he shot *An Icy Night*; *Spring Showers, The Coach*; and *Spring Showers, the Sweeper*. Also he began experimenting with his 'portraits in time,' believing that no one picture could convey the complexity of a person, he took a series of photos of the individual. Kitty, his daughter, was the first subject. The memorable series of portrait photos of O'Keeffe and later of Dorothy Norman taken decades later had their start during this period.

After 5 years at the club's helm, a fast-growing rift emerged between Stieglitz's high aims and some of the members' views. Some thought he was an elitist, an autocrat, and self-absorbed. The apocryphal tale of the young Alfred, the organ-grinder, and the monkey, may help decode this split: inarguably Alfred was giving away his time and talents – he took no salary for all his work. Yet there can be arrogance and tyranny to generosity. Disgruntled members may have felt like the monkey who didn't necessarily like the handout. Although Stieglitz left with a dramatic flourish ridiculing the amateurish attitude that seemed to take over the club, his critics did not take his criticism lying down.

Despite insulting exchanges, many highly trained and esteemed photographers, including Eduard Steichen, Gertrude Käsebier and Clarence H. White, sided with Stieglitz's preferences for pictorial photography and they exited with him, beginning an independent movement. The movement was dubbed the Photo-Seession, modeled after the Viennese Secession. His last edition of *Camera Notes* as editor was in July of 1902. Under a more 'understanding' editor, *Camera Notes* continued for only one more year. And Stieglitz soon published a new journal called *Camera Work* and simultaneously moved on to create one of the most interesting alternative art spaces of the early twentieth century. First of all, it was a physical space the Secessionist could call their own.

The Little Galleries of the Photo-Seession: '291'

On Fifth Avenue between 30th and 31st Streets, a row of brownstones stood. Once quite fashionable in the late nineteenth

century, by the time Stieglitz moved, the brownstones were taken over by small offices and shops. Elite New Yorkers had moved uptown. The urban landscape was fast changing – eight blocks away the just completed Flatiron Building transformed the skyline and would captivate photographers, including Stieglitz, for years to come.

It was the young Eduard (later Edward) Steichen who discovered 291. Steichen, a Lithuanian-born painter as well as a photographer, located a studio for himself that was reasonable in rent and allowed him a street level showcase for his photography – there he hung his shingle as a professional portrait photographer. He photographed J. P. Morgan, Eleanor Duse, and in France took many photos of Auguste Rodin and his statues of Balzac – quite revolutionary for their time and still today they are seen as some of the landmark images in establishing photography as fine art. As his reputation for portraiture grew, he expanded his studio space and rented 293, leaving 291 vacant.

Steichen, 15 years younger than Stieglitz, was admired much by the older artist who called him ‘his man’ when they met. Steichen became one of several key colleague-advisors who influenced him and helped him mount shows over the years. Stieglitz embraced him and welcomed him into his family. When Stieglitz separated from the Camera Club, he trusted Steichen’s judgment and took his advice about turning the Steichen studio into a gallery where paintings as well as photographs could be hung. Steichen planned to return to France and promised that he would get a Rodin drawing exhibition for 291 – the show, hung in January of 1908, marked the beginning of systematically initiating and expanding the public’s taste for modernism.

Now the Photo-Secession Group not only had a name but it had a place and a future. The formal name soon morphed into ‘291.’ The gallery opened in 1905 and closed in 1917 when World War I began. Stieglitz saw the space as a laboratory rather than a commercial art gallery. And what did this lab look like? Enter the narrow building and go to the top floor in a small, creaky, man-operated elevator. Step into a space defined by three rooms with a vestibule leading into a small art gallery, a 15 foot-square room, in the center is a table with a very large copper bowl holding dried flowers. The room is unpretentious but elegant. Steichen chose the colors for 291 – olive painted walls with warm olive-gray burlap pleated drapery covering the lower half of the walls; the two other rooms maintained the muted color palette and introduced pure white moldings and woodwork to offset the subdued color scheme.

A ‘spiffy’ space does not a creative environment make. What made this place special were the exhibitions. Starting with the 1905 opening exhibit of 39 Secessionist photographers including Stieglitz, Käsebier, Steichen, and White, 291 went on to exhibit the foremost photographers of the early twentieth century including Paul Strand and Paul B. Haviland. The gallery did not limit itself to photography but quickly expanded to include paintings and sculpture which ultimately surpassed the photography shows in number and attendance. Placing paintings in a photography gallery was a clever means of raising the status of photography. Although Stieglitz’s aim was to bring an American sensibility into the world art scene, he also brought to New York the work of the most innovative French artists which included not only the ones mentioned earlier but also

Henri de Toulouse-Lautrec, Pierre August Renoir, and Henri Rousseau. In addition African Sculpture and shows of children’s drawings were exhibited. All in all there were 79 shows mounted at 291 in 13 years. The gallery functioned as a museum of modern art – note that the founding of New York’s illustrious Museum of Modern Art occurred in 1929, more than a decade after the close of 291.

The People and the Ideas

Beside the art exhibitions, the people made 291 special – the artists, students, poets, critics, collectors, and the general public. The people provided and were the excitement. If you wanted to see something new and exhilarating you went to 291. And if you were lucky enough, you might watch Stieglitz hold court and experience his animated, charismatically charged comments on American Modernism or you might find him arguing with the students from the Art Students League, a rowdy group who mocked the high seriousness of Stieglitz’s ideas. At noon a group of artists and poets gathered – The Round Table – who would then proceed to lunch together at a local hotel. The place, although physical and tangible and architectural, represented something intangible – it was a home – a haunt – for those who felt like ‘the other.’

Others shared not only the space but an ideological perspective – a set of beliefs, preferences, and values. First, the Stieglitz circle favored the primitive. They agreed that sexual impulses drove artistic creation. Second, the credo of symbolism with its emphasis on the personal and the soul was very appealing. Capturing and working from inner states rather than analytic ones produced work that was universal. Last among the pivotal ideas were those focused on ‘Woman’ – the group developed a romantic rhetoric rhapsodizing the ‘woman-child’ – a pure, clean erotic woman, free of bourgeois guilt.

Stieglitz was ahead of his times in respect to exhibiting the work of women and homosexual artists. This sponsorship was not a political statement but an esthetic one. It is not common knowledge that Stieglitz sponsored many women artists before meeting O’Keeffe. Although O’Keeffe represented the iconic woman artist for him, he tried to find the ideal woman in art many years before meeting her. His views of the sexes were situated in early twentieth century gendered views – woman as pure, child-like, and sexually charged. Some saw him as a womanizer who rationalized seduction with flowery romantic rhetoric yet these women’s work merit attention and recognition. And recently they have been rediscovered and their work has been shown in several venues.

Stieglitz’ sponsorship of homosexual artists including Charles Demuth and Marsden Hartley was also progressive. Stieglitz was not a gay rights activist, but put talent first. Stieglitz’s connoisseurship extended to selecting colleague-advisors: Eduard Steichen, Marius de Zayas, and Max Weber to name but a few served as conduits to art and artists abroad. They informed him about new developments, advocated certain styles, and had the connections which made exhibitions possible.

Camera Work

The elegant magazine *Camera Work* (1903–1917) published by Stieglitz extended 291’s influence by presenting stunning

reproductions of the photos on exhibition and essays on art. *Camera Work* introduced works of such writers as Gertrude Stein to Americans. *Camera Work* blended both literature and the visual arts. Arbitrary boundaries among and between the arts were challenged in essays comparing, for example, Matisse and Isadora Duncan. The magazine's implicit mission was to unify all the arts illustrating the plurality of modernism and thus counterbalance the lack of soul in profit-mad materialism.

During this heady period of running 291 and editing *Camera Work*, Stieglitz himself took some unforgettable, iconic images. The most famous was 'The Steerage' taken in 1907. Here, he captured the lower level of the ship, where men, women, and children were crowded into a small space. The picture was taken from above, from the space of the wealthy whose pretensions he ridiculed. The interrelated shapes of the families in steerage were spellbinding for him and he was willing to stake his reputation and legacy on that one image. The second block-buster image taken in 1902 was 'The Hand of Man' where a locomotive spewing black smoke moves toward the viewer, train tracks elliptically crisscrossing and telephone poles in the background. The clout of industrial America loomed forebodingly large and the symbolism in the photo intrigued Stieglitz so much that he worked on it in multiple ways for many years.

Although he was to open other gallery spaces in the future, Stieglitz closed 291 in 1917. Why? The war and rising costs of running the gallery were central to the closing; subscriptions to *Camera Work* plummeted. Another more subtle factor was that 291 was no longer the center of art experimentation. The Armory Show in 1913 was pivotal in exposing US audiences to European vanguard esthetics and resulted in the opening of several new art galleries that showed American and European modern works.

The O'Keeffe Years: 1916–1946

Georgia O'Keeffe, then a struggling artist who was teaching school in Texas, had been aware for some time of '291' and the impressive, charismatic Stieglitz. Although she had not met him formally, she had visited the gallery with school chums from the Art Students League years before. She valued his opinions and artistry. Her school friend, Anita Pollitzer served as a conduit and brought to 291 some of O'Keeffe's drawings. Stieglitz was astounded by the beauty of the drawings and announced, or so the story goes: "At last a woman on paper." On 22 May 1916, Stieglitz exhibited ten O'Keeffe charcoal drawings in a group show. There was great enthusiasm for her work within the Stieglitz circle and in 1917 Stieglitz held the first solo O'Keeffe exhibition. He convinced her to join him in New York and offered her the opportunity to do nothing but paint and she grabbed the opportunity. She met Stieglitz when she was 29 and he 58. Some maintain, falsely, that this is when her life as an artist began. More accurately, he did not create her – she was already an excellent artist – but he discovered her and promoted her. With her consent and cooperation, they fashioned her iconic status and forged one of the most exciting collaborations in modern art. His great gift to her was the time to develop her then considerable talent and unique perspective; parenthetically he gave this gift to other artists as well

including John Marin. She in turn gave his work new life and direction, and upon his death in 1946 at 82 years old, she vigorously and systematically protected his legacy in American photography.

Knowing O'Keeffe inspired Stieglitz who was trapped in a loveless marriage. He was enamored with her genius and her person and took hundreds of photos of her – deconstructing her body, showing her torso, her breasts, her hands, and her face. These photos, taken over many years, reveal an evolution in his perception of her from girlish innocence to androgynous siren to a steely modern presence. His legacy is enhanced by these stunning images.

After his divorce, they married because he wanted marriage. She maintained her name. Several years into their relationship and after their marriage, O'Keeffe became severely depressed. She had already achieved considerable recognition and was financially secure yet her life and marriage unraveled. She recovered and her dependency on Stieglitz lessened; she knew the worst side of him as well as his genius for encouragement. She stayed in the marriage until his death but spent significantly less time in New York and found a second home in New Mexico. In 1929 he established his last gallery, An American Place, which remained open until one month before his death in 1946. He showed his own photographs and those of Ansel Adams and Eliot Porter as well as the regulars of the Stieglitz circle.

The Stieglitz Legacy

Stieglitz left us a body of photographic work which is memorable in vision, technique, and accessibility. His influence on photography was immense. He was tireless in his promotion of photography as fine art. Besides his leadership role in photography, he accomplished something few artists ever contemplate. He fostered a creative environment for others. His gallery, 291, served as a noncommercial space for the public and artists to gather and view and discuss art.

What did we learn from Stieglitz's life and the establishment of 291 that can be generalized to other creative environments? Foremost, you need a compelling, towering, creative person with a big vision to construct a viable space. That vision has to be coupled with a drive, a passion to fulfill the dream. The leader becomes the voice, the propagandist for creative activity. Attracting and keeping astute colleague-advisors should not be underestimated. So much of the formation and maintenance of 291 was spurred by Steichen's actions and connections. Resources are essential because somebody must pay the bills for the space. Besides vision, extraversion, finding wise colleagues, and resources, the ability to spot and nurture talent is absolutely necessary. Much of the time Stieglitz was inclusive and not divisive. If the person had talent and had something new to say, sexual orientation and gender were irrelevant.

Creative persons, creative processes, and creative products are routinely studied yet creative environments and the people who mount such spaces are given short shrift. In examining Stieglitz's life, we identify multiple factors associated with his ability to construct a creative environment which benefited artists as well as the public at large who now view his vast personal collection of European and American paintings and photography in major museums throughout America.

Glossary

Creativity The way of thinking leading to creative products or ideas that are deemed to be novel or original and useful or adaptive.

Divergent thinking The kind of thinking that results in numerous ideas or solutions, as opposed to convergent thinking, which leads to one correct solution or idea through deductive reasoning.

Flow State of complete immersion in a task characterized by effortless performance, extreme task-engagement, and positive feelings. It usually results in creative products.

Personality traits Stable and enduring dispositions of behavior and beliefs.

Psychological states Transient internal conditions that are immediately accessible to the individual.

Stress state State experienced when individuals feel they lack psychological resources to respond to an external or internal stimulus and/or perceive it as a threat to their well-being.

Trait emotional intelligence (trait EI or trait emotional self-efficacy) A constellation of emotional self-perceptions located at the lower levels of personality hierarchies. It includes factors such as emotionality, sociability, well-being, and self-control.

Creativity and Affect: Two Lines of Research

Creativity

Although there is ongoing debate in the general psychological literature about the operationalization of creativity, the construct has been defined fairly consensually as a way of thinking that leads to novel and useful products or ideas. Despite the consensus about a general definition of creativity, the conceptualization of factors influencing creativity is often more complex and multicomponential. Cognitive ability, cognitive styles, personality, and motivation have all been suggested as contributory factors.

The study of the affect-creativity link, including work focusing on stress, has commonly used divergent thinking as an indicator or marker of creativity. It refers to the type of thinking that results in several ideas or solutions, as opposed to convergent thinking, which leads to one correct solution or idea. Divergent thinking tests are thought to measure idea generation and in particular, aspects such as fluidity, flexibility, originality, and elaboration. They have been shown to have certain predictive, convergent, and discriminant validity. However, apart from some methodological limitations, one of its shortcomings is that while they seem to work well for quantifying creative aspects such as originality, their ability to measure the usefulness of the responses has been contested.

There has been extensive empirical investigation of the more cognitive elements of creative activity, but less for affect-related components. Two main approaches to the creativity-affect link can be identified in the literature. The first is the study of affect-related personality traits in relation to creativity. This issue has been addressed indirectly using constructs from general personality theories such as the *Big Five* or the *Giant Three*, and more recently using specifically affect-related personality constructs such as trait emotional intelligence (trait EI or trait emotional self-efficacy). Trait emotional intelligence refers to a range of emotion-related self-perceptions and dispositions located at the lower levels of personality hierarchies,

including factors such as emotionality, sociability, well-being and self-control. The second line of research refers to the relationship between affect-related states and creative performance. Literature on the links between creativity and psychological states, or on state-task links in general, makes use of terms such as 'emotional state,' 'affective state,' and, more commonly, 'mood states,' which isolate a single dimension of the emotionality or affectivity of a state. The term *mood* has been used in several ways; first, as a summarising dimension for subjective states in general, emphasizing the emotional dimensions of states, examples being positive or negative *moods*. Second, moods may be defined as states that arise independently of identifiable triggers. Thirdly, moods can be conceptualised as states that are persistent enough to influence other states, behaviors and cognitions over time. Clearly, the uses of the term are somewhat varied in the literature, and do not form a single agreed definitional tool. Another important terminology clarification is that between *moods* and emotions. Generally, moods, contrary to emotions, are long-lasting, diffuse and global.

The two creativity-affect lines of research are partly reflected within a theory proposed and developed by Sandra W. Russ, where both general personality characteristics and affective states act as facilitators for the cognitive processes associated with creativity, such as divergent thinking.

Traits and States

Since affect-related personality traits have emerged as a focus of creativity research, it has become more important to be able to distinguish between the two concepts of trait and state. The literature defines personality traits as stabilities of behavior and beliefs about our enduring dispositions, while psychological states are transient internal conditions. Unlike states, which are directly experienced by the individual, traits reflect propensities toward particular feelings, thoughts, or behaviors. They can be measured indirectly via characteristics or responses which

describe or predict these tendencies. Traits can also be defined conditionally in terms of their likelihood of occurrence in specific situations and contexts. Traits and states are also theorized to have different relationships to behavior. Psychologists have generally recognized that behavior is influenced by an interaction between traits and situations. Subjective states are immediate elements of experience, and they are viewed, in turn, as the product of this interaction between personality traits and the external or internal situation. In other words, subjective states are determined wholly by a combination of psychological, physiological, and situational factors.

Having defined the key concepts under review, an overview of the two existing lines of research on the link between creativity and affect is provided below. As mentioned earlier, these are the study of emotion-related personality traits in relation to creativity and the role of subjective states in creative performance. Specifically, the focus on trait emotional intelligence and divergent thinking. After a review of the literature on valenced subjective states, research involving stress state dimensions is presented.

The Two Lines of Research

Affect-related traits and creativity: The case of trait emotional intelligence and divergent thinking

The literature on links between affect-related traits and creativity is informed mainly by empirical work based on trait emotional intelligence and divergent thinking. The studies conducted so far have generally found no overall correlation between global trait emotional intelligence scores and divergent thinking. However, this null correlation may conceal different relationships between divergent thinking and the separate factors underlying global trait emotional intelligence. In a recent study, María José Sánchez-Ruiz, Daniel Hernández-Torrano, Juan Carlos Pérez-González, and K. V. Petrides found certain trait EI factors such as *sociability* (i.e., assertiveness, emotion management, and social awareness) to be positively related to divergent thinking, while others such as *self-control* (i.e., emotion control, impulsiveness, and stress management) were related negatively to it. The latter finding is consistent with positive correlations found elsewhere between divergent thinking performance and emotional instability and between divergent thinking performance and affective disorders. Despite these results linking low self-control and creativity there are also some inconsistencies; for example trait anxiety – an aspect theoretically related to low trait self-control – has also sometimes been correlated negatively with originality and innovativeness. Some studies have also found anxiety to be negatively correlated with divergent thinking, or to be unrelated. In sum, results about the relationships between creative performance and the regulation of emotions and control of anxiety are rather contradictory.

The apparent contradictions in whole-population correlations may make more sense in the light of evidence that the relationship between creativity and affect also has a domain-specific component. Creative individuals appear to experience more anxiety, higher affect intensity, and show less control over their emotional experiences in the arts than in the sciences. In addition to the differences in personality and affect traits of individuals across domains, there may also be variation by domain in the relationship between those traits and

creative performance. In the arts domain, but not in other domains studied, high levels of emotionality and low levels of self-control seem to be good predictors of divergent thinking skills (see Sánchez-Ruiz et al. under review), although these findings require replication in future studies. Overall, the relationship between affect-related traits and creativity is potentially quite complex, and particularly for research specifically addressing stress.

Subjective states and creativity

The second strand of creativity-affect research deals with subjective states. Here attention has focused mainly on the valence of states, but the association between creativity and positively or negatively valenced states remains inconclusive. On the one hand, some correlational studies, experimental studies (using affect-induction methods), and meta-analyses suggest that positive affect enhances creativity. This is supported by research on bipolar disorder reporting that positively valenced states (moderate ‘mood’ elevation) are associated with creative performance. On the other hand, some studies find positively valenced states inhibiting creativity, and negative states facilitating it. A possible mechanism for this is that negatively valenced states enhance creativity through increased task persistence and perseverance, whilst positive states promote satisfaction and reduce motivation to seek better quality outputs (for further discussion on this suggestion see the next section).

However, even if definitive findings emerge linking creativity to the valence dimension of states, the positive/negative bipolarity may turn out to be too restricted to explain the complexity of affective state relationships with creativity. Some authors have already criticized the concentration of research on valence. States, particularly negative ones, can have complex dimensional structures and two ‘negative’ states can be different enough to have contradictory effects in relation to creativity. Other dimensions need to be considered, such as activation. Activating states such as anger, fear, or happiness may conceivably lead to more creative fluency and originality than deactivating states, such as sadness, depression, or relaxation as the former involve drive and motivation to act. Examination of the relationship between creativity and the underlying dimensions of stress state, considered to be a negative and activating state, may give new insights into the creativity-affect link and the specific associations between creativity and anxiety, self-control, and emotional instability.

Stress State and Creativity: Possible Relationships

A stress state is a psychological state which accompanies stressful situations and stimuli. It can be identified by subjective, contextual, and physiological indicators, and it is multidimensional as it has several underlying factors. In general, states are influenced by appraisals of environmental threats, opportunities, and personal capability. These states will in turn influence the individual’s situational response – actions, coping strategies, or avoidance. The overall process is a transaction between individual and environment, and states play a part in that process.

On this basis, a stress state (or response) is theorized as the dynamic relationship, or transaction, between an individual

and the situational stressors. Specifically, the stress state is the result of a relationship between the individual and the situation that is perceived as too demanding and threatening to his/her well-being.

The affective component of the stress response has been equated with the emotion of anxiety. The situational focus for this emotion is also a 'threat to the self,' and perceived lack of capacity to address that threat (lack of self-efficacy). By extension, trait stress is a propensity to experience, and be preoccupied by, an emotion relating to threat and inadequacy. The operationalization of stress state is complicated because it is identified with appraisal of threat, inability to respond, and incapacity due to introspection. The stress state involves aspects of cognition (appraisal or perception of the stimulus), emotion (negative mood), and motivation (e.g., task interest, concentration).

The association between stress state and creativity can have implications for different contexts (e.g., education, organizations). Many researchers have realized this and studied the topic but a number of aspects remain ambiguous. Stress reduction through relaxation techniques has been found to increase creative performance in experimental and nonexperimental settings. However, not all studies have found a definite relation between stress level and creativity. Other studies of creativity, categorization, and cue utilization tasks found no significant effect of negative stressful states, induced by techniques such as sensory deprivation or the use of distressing films.

Studies of stress and divergent thinking in particular have also led to conflicting results. Stress state appears to undermine performance in some studies, whilst in others positive state induction and reduced anxiety have been unrelated to divergent thinking on figural tasks. Some research indicate that divergent thinking is positively related to trait and state anxiety and negatively related to self-control (discussed in the opening section). Another set of results suggest an inverted U-shaped relationship between stress response and divergent thinking, whereby increases in stress state levels are associated with improved divergent thinking performance, up to a certain level, but that further increases are accompanied by a performance reduction.

Possibilities for the Stress-Creativity Link and Tentative Explanations

Negative stress-creativity relationship

Some physiological mechanisms have been proposed for a negative relationship between stress state and the divergent thinking aspect of creativity. Individuals in positive states appear to also have better access to memory than individuals in negative states (such as a stress state). In addition, valenced states tend to elicit memories of the same valence, and positive material is generally more extensive in memory than negative material, again allowing positive states to facilitate generation of creative ideas.

Some information processing models suggest that negative affect also impairs creativity by increasing cortical arousal, which leads to fewer active nodes in memory, and consequently fewer unusual associations. The increased arousal associated with stress, fear, or frustration creates a preference for a more predictable or conventional response over more unusual

responses and also for more constricted thinking and cue utilization. Confirming this, greater creativity on a task has been associated with lower levels of cortical arousal.

A further potential explanation for a negative stress-creativity association is that stress state demands attention and individuals have limited mental resources; therefore, when individuals experience stress state, fewer resources are available for other tasks such as creative tasks. The resultant use of simpler cognitive strategies undermines the production of original ideas.

In sum, some of the possible explanations for a negative association between stress state and creativity are that stress state elicits less material in memory, that it increases cortical arousal, which means fewer active nodes, and that it leads to a reduction of the attentional focus.

Positive stress-creativity relationship

Stress state may also promote creativity, as some research has found, through increasing task-engagement and motivation to seek solutions. Individuals under state stress may concentrate more during problem-solving strategies resulting in more new and valuable products. Stress reduces the tendency to satisfice or accept ideas as they come and so may be linked to more analytical elements of creativity, such as evaluation and systematization. This suggestion is in line with the theoretical framework developed by Mark Runco that argues for negative affect and tension as antecedent conditions for creativity, and for dissatisfaction as a factor driving and motivating relevant performance.

Dual pathway relationship

A positive impact of a negative state such as stress on creativity does not exclude the possibility of positive states being also beneficial to creativity. Some tentative explanations argue for a dual-pathway for the relationship between affect and creativity. This approach suggests that positive activating states may be linked to 'cognitive flexibility' and thus facilitate creative performance, and that activating states with negative tone may also be creativity-enhancing in terms of 'perseverance.' Positive moods may be supporting the divergent thinking component of flexibility, establishing more categories of response, while persistent hard work and thorough exploration driven by the stress state may lead to the divergent thinking components of fluency and originality manifested in the generation of many ideas within a few categories.

Curvilinear stress-creativity relationship

A nonlinear relationship has been found between creativity and stress in some studies. Specifically, divergent thinking performance (on verbal tasks) seems to be lower in individuals in conditions of high stress and low stress than in participants in moderate conditions, in an inverted 'U' shaped relationship (corresponding to the classic *Yerkes-Dodson law* relating arousal and general task performance). Similarly, fluency has shown to be highest in individuals in a condition of moderate stress activation. Research on bipolar disorder and its relationship with creativity has shown that the elevation of mood that comes with the disorder may enhance creative behavior. In sum, moderate levels of stress may provide the arousal needed for creative tasks without diminishing cognitive resources.

In general, research on stress states and creativity suggest that while intense stress state lessens creativity, especially for complex and demanding tasks, the effects of moderate and low levels of stress are less clear. One of the conclusions that can be drawn from various studies is that the relationship between stress state and creativity cannot be reduced to a 'negative or positive' issue, and may be influenced by a number of mediators. Some of these mediators are discussed in the next section.

Challenges in the Research on the Stress–Creativity Link

A number of specific challenges can be identified in the literature about stress–creativity links. First, the conceptualization of psychological states has involved a definition mainly in terms of positive or negative aspects, ignoring other dimensions on which creativity may vary. Second, little attention has been paid to the potential domain-specificity component of the relationship between creativity and affect states. Third, the link between creativity and affect has been measured, analyzed and presented in a way which assumes a unidirectional relationship of states to performance, while reverse and reciprocal directions of the effect have been less explored. Fourth, the literature has suffered from a dual failure in the operationalization of creativity. In many instances creativity has not been independently measured using a standardized and validated instrument. Also, where such instruments have been used, the range has often been narrow (focusing on divergent thinking without exploring other aspects of the complex phenomenon of creativity). Results from different studies have shown that the use of different creativity indicators may lead to different results. Finally, there is a paucity of research considering the influence of both personality traits and subjective states on creative performance.

The Role of Stress State Dimensionality and Type of Stressor

Much previous research into the creativity–affect link has defined states in terms of positive and negative categories. However, as noted earlier, some authors have pointed out the general desirability of moving beyond a one-dimensional construct of state in examination of task–state links. Other conceptualizations of states as multidimensional phenomena may open new doors to the study of creativity and stress. In this sense, holistic terms such as 'subjective states' may better describe the complexity of the term. This is particularly relevant for the example of stress because stress state is multidimensional and the view of negative or positive affect phenomena is thus too restricted. Gerard Matthews et al. have highlighted that the stress state has emotional, motivational, and cognitive components. As noted earlier, creativity is also influenced by each of these three aspects. In particular, these authors have identified three dimensions of the subjective state of stress: distress, task-engagement, and worry. Future research on the stress–creativity link should then go beyond the conventional positive/negative affect distinction in examining the creativity–state link. A multidimensional stress state conceptualization and operationalization will lead to a more complete picture of its relationship with creativity.

Experimental research on the effect of stressors on creativity has shown that the relationship depends on the type of stressor used and the intensity of its effect, as well as the type of stress that is provoked. Kristin Byron, Shalini Khazanchi and Deborah Nazarian investigated the effect of two stressors: social-evaluative threats (e.g., videotaping, presence of evaluative elements) and uncontrollability (e.g., time constraints, false negative feedback, noise) on creative performance. Social-evaluative threats were found to either increase or decrease performance while uncontrollability served only to impair it. Overall, low-stress inducing situations supported creative performance while high stress-inducing situations had the opposite effect. This shows how, in addition to considering subjective stress state dimensions, when appropriate, the specific type of stressor should be taken into account, since results may vary according to both variables.

The Role of the Domain Specificity of Creativity Correlates

Domain specificity has been increasingly recognized as a key issue in creativity.

In general, differences in personality traits across domains have been repeatedly evidenced in previous research. Specifically, artists have shown higher levels of emotional expressiveness and have shown to be more sensitive to their feelings than scientists. Also, artists tend to experience more negative affect, be more impulsive, and have shown lower levels of emotional control than scientists. In terms also of the relationship between affect and creativity, the results from the study by Sánchez-Ruiz et al. show that, when considering domain in the analyses, the negative relationship between divergent thinking performance and the trait emotional intelligence factor of self-control (which includes the stress management facet) is only true for artists but not for technical and natural scientists, and social scientists.

There is need to replicate these results at the psychological state level. The relationship between stress state and creativity may be similarly influenced by domain. It may also be the case that such relationships can vary by domain and by state dimensionality. To test the possible combinations of state dimensions and creative performance by domain, a multidimensional conceptualization of states is needed, as well as the inclusion of domain as a variable in the research design.

Also, there may even be an additional effect due to the relevance of the task itself to the domain. For example, arts students were more likely to experience a positive change in psychological states after completing a creativity task that is congruent with their domain as shown in a study conducted by Gregory Feist. This may suggest that domain specificity of task is more important in relation to performance for artists than for other groups.

In conclusion, a lack of focus on domain specificity in designing samples and analysis can cause problems for investigations of the creativity–affect link. Since traits and states are related to domains, some conflicting or ambiguous results in the literature on the relationship between psychological states and creativity may therefore be due to the use of differing domains or differently balanced samples. Future studies can overcome this limitation by including comparisons among various domains (beyond the traditionally considered: sciences and arts) and in any case, by specifying the participants' domains.

The Role of Temporality

Another aspect that has been a challenge for creativity-affect studies is dealing with temporal ordering, and there is now some recognition that ignoring this may lead to equivocal conclusions. Empirical studies on stress state links with creative tasks have typically assumed that psychological states impact upon creativity and are an antecedent of it. However, whilst prior states may be predictive of creativity, it is also possible that within-task states and creative performance both affect each other.

In terms of addressing this directionality, some suggestions and hypotheses have been advanced about the power of creative insight to provoke feelings of elation and some isolated empirical studies have measured psychological states before, during, and after a creativity task (e.g., Feist). Despite the paucity of research addressing temporal ordering in the association between subjective states and creativity, there is some theoretical support for models involving a two-way dynamic relationship between both phenomena. For example, the notion of the flow state, in which the individual focuses and totally engages in the performance of a task, and experiences affective states of enthusiasm and enjoyment whilst engaged in creative activity. A complementary explanation of the relationship between creativity and affect is that prior intrinsic motivation drives creative activity, which in turn feeds back into positively valenced states (i.e., enjoyment). However, these hypotheses are testable only through well-established measures and systematic empirical designs. Similarly, research allowing for temporal analysis of stress state dimensions can help explore possible pathways of influence of stress state on creativity and vice versa.

The Role of the Creativity Criteria

A general shortcoming of the literature on the link between creativity and affect is the widespread failure to use a standardized and validated instrument designed to measure creativity. In some cases, researchers have used context or domain as the creativity criterion, without applying any measure of creative performance, assuming that individuals are more or less creative merely due to their domain of performance. To date, where standardized measures have been applied, divergent thinking has typically been used to operationalize creativity which gives a quite restrictive view of creativity as a complex phenomenon with its other aspects being neglected. This is important because different criteria of creativity will demonstrate different patterns of association with other psychological constructs. As we have stated at the beginning of this article, divergent thinking tests also have their own limitations.

There is evidence that relationships between creativity and affect-related states vary across criteria of creativity. Not only the relationships between creativity and stress may differ according to the creativity criteria, but within one criterion, such as divergent thinking, variation may come from the different subscales. Several studies have shown that different aspects of divergent thinking, such as fluency and originality demonstrate different patterns of relationships with personality traits and with trait emotional intelligence. For example, when examining the link between divergent thinking aspects and overall valence of psychological states, positively valenced states were related to idea quantity (fluency), but not to idea

quality (originality). This is consistent with the argument that the relationship varies depending on whether the generative or critical functions are being considered. Similarly, Carsten De Dreu et al. argued that states and traits do not necessarily influence creative performance via one pathway, but instead can operate multidimensionally, with different factors such as valence or activation enhancing one or other element of creativity. Therefore, future studies will benefit from including different creativity criteria in the research designs. Also, researchers should avoid overgeneral conclusions being drawn from more limited studies, as it is difficult to establish assumptions for the construct of creativity in general when only one indicator of creativity has been used.

The Relevance of Trait-State Models

Creativity has been related to affect, and more specifically, to stress, in terms of both traits and states. There is nevertheless a need for research considering both lines of research simultaneously, that is to say, affect-related traits and states should be both linked to creativity within a single study. Affect-related traits and states have both been linked to creativity, but not, to date, within a single unified analysis. Traits and states can jointly predict behaviors more effectively than they do separately, therefore trait-state models to study behaviors are to be advocated in research on the relationship between affect and creativity.

Conclusions

In this article two main lines of research on the issue of affect and creativity are reviewed. The first focuses on personality traits, and specifically, on affect-related traits and creativity. This line has been dominated by the traditional measures of general personality traits. However, recent research in this line has successfully related creativity to the trait emotional intelligence framework. The second line centers on psychological states and their relationship with creative performance. Here the results so far show contradictions, and this extends to the relationship between stress state and creativity. As reflected in this review, research has not yet clarified whether stress states foster or decrease creativity performance (and vice versa). The stress-creativity link seems to be a complex one and is unlikely to be resolved by assuming that it is either positive or negative. In the previous sections of the article, some challenges and limitations regarding research on affect and creativity have been discussed, namely the narrow affect-state dimensionality, the poor differentiation of domain, the lack of temporal modeling of research designs, the use of a unique (and sometimes limited) criteria of creativity, and the underuse of trait-state models to research the topic. These issues may play a key role in the nature and direction of the effect in the creativity-affect relationship. Lastly, conclusions are drawn and some research and practical implications are provided.

Implications

Knowledge of the detailed relationship between stress and creativity and addressing the challenges presented may have implications for psychological, educational, and organizational contexts.

The study of the stress–creativity link brings recognition of the benefits of a multidimensional view of subjective states. These include allowing the domain specificity of the creativity–affect link to be more accurately identified and resolving some of the apparent contradictions affecting results for single-dimension state measures. Different relationships between different stress dimensions could be then identified across domains. Furthermore, the type and intensity of the stressor has proven to be relevant, and this has implications when managing the environmental factors that relate to creative process. Domain can be a major source of variation in affect-related traits and states, and also in the relationship between creativity and stress state. Research including the domain variable can validate and improve existing taxonomies of general and specific requirements for creativity in order to build a well-grounded theory of the domain specificity of creativity.

Examinations of domain specificity of the stress–creativity link at the state and trait level can support the understanding and promotion of creativity within domains in real life contexts, by revealing which individual characteristics and task conditions enhance creative performance within a domain and how stress dimensions can affect it. Effectively designed research can also identify barriers to creativity across domains, and challenge and dispel myths about which groups are more or less creative in different situations. Such understanding may serve to vocational training and support and may be of help, not only vocational, but also to academic counseling practitioners.

As stated in the previous section, the stress–creativity relationship may be bidirectional. It is important to consider the implications of the temporal sequencing of states and performance tasks. Psychological states can modify and be modified by performance in creativity tasks. Future studies may therefore find important effects of creative activity and behaviors on subjective states, and potentially on affect-related traits over the longer term. Experimental and longitudinal studies with repeated measures could provide more information about these interactions throughout the life span, thus helping establish causal relationships, if these exist.

There is evidence that relationships between creativity and affect vary not only across different affect phenomena, but across criteria of creativity. There are clear differences in the pattern of associations between two established creativity measures and affect-related traits and states. This strongly implies that it would be worth exploring different aspects of creativity within different creative and vocational contexts, to obtain better ecological validity.

Lastly, empirical research on creativity and states infrequently explore the creativity–stress association at the state level, whilst considering the trait level as well. Exploring trait emotional intelligence in relation to creativity provides insight into the influence of emotional-based self-perceptions and dispositions on creative performance. Considering trait emotional intelligence (and the effects of general personality factors) and subjective state effects in the same research design can also be helpful when the aim is to determine the predictability of the latter (e.g., stress state) controlling for the influence of the former (e.g., self-control). Future research may therefore need to explore the creativity–affect association at the state level, considering the trait level as well, through a

multidimensional conceptualization of states and the trait emotional intelligence framework, respectively.

Final Conclusion

In summary, it is clear that the development of a research line focused on the links between creativity and the stress state offers real theoretical and practical benefits. Experimental methodologies accounting for domain specificity have the potential to give a clearer picture of the bidirectional relationships between aspects of creative performance and long and short term affects. Multidimensional stress state components, which are also linked with general task performance, will play an important part in this work. Future research will need to examine the influence of personality traits on creativity, and the mediating and reciprocal relationship that subjective states (including stress) may have with the latter. Traits and states, when measured simultaneously, will provide a clear indication of their respective role in creative performance.

To conclude, there are still a number of challenges to meet and many issues to be clarified in relation to the creativity–affect link and the creativity–stress link in particular. The ways the study of these matters can move forward are through a structured and grounded theoretical framework, innovative and rigorous correlational and experimental research designs, and well-developed and reliable measures.

Glossary

Alcoholism Repeated intake of alcoholic beverages to an extent that causes repeated or continued harm to the drinker.

Hallucinogen Includes LSD, mescaline, and peyote. Causes hallucination by disrupting the interaction of nerve cells and the neurotransmitter serotonin. Psychological effects are similar to dreams, schizophrenia, and religious exhilaration.

Substance abuse A continuing pattern of using a substance such as drugs or alcohol to the point where it infringes on

the ability to function normally in social or occupational roles.

Substance dependence A state arising from the repeated administration of a drug on a periodic or continual basis to the point where an individual's activities are focused primarily on obtaining the substance and taking it. Tolerance can build up requiring higher doses of the addictive substance to achieve the same effect and failure to obtain the substance can lead to withdrawal symptoms.

Introduction

The relationship between creativity and substance abuse is complex and far from fully understood. There is a myth surrounding the use of alcohol and drugs that is sustained by the dramatic acting out of individuals under the influence and the high number of creative individuals who have been publicly identified with abuse and addiction problems. The fuzzy notion that somehow drugs and alcohol improve creativity is based on the romantic misconception that these substances release inhibition allowing insights and creative achievement to flow. Very little objective research or self reports from creative individual support this idea.

In order to understand whether substance abuse is higher than average in creative people we need to establish a baseline. On a worldwide basis this can only be done with alcohol. The World Health Organization in 2004 estimated 2 billion people drink alcohol with 76.3 million who have diagnosable problems. The estimate is that 1.8 million deaths (3.2%) are alcohol related. Consequences of heavy drinking include acute health problems, traffic injuries and deaths, accidental injury including alcohol poisoning, suicide, high risk sexual behavior, and violent crime. There are also serious social and economic ramifications related to alcohol use.

Many Muslim countries, where there are primarily abstainers, have a very low percentage of alcohol dependence while other countries have very high levels of alcohol dependence, especially among men. These include South Africa (27.6%), Poland (23.3%), Peru (17.8%), Brazil (17.1%), Canada (14%), France (13.3%), Iran (11.9%) and the United States (10.8%). The Russian Federation is not included on the list although it has very high alcohol dependence and abuse which has been a factor in low life expectancy.

The US Department of Health and Human Services Substance Abuse and Mental Health Services Administration conducts a national survey on drug use and health. In 2008 they estimated that 22.2 million people over the age of 12 (8.9%) were dependent or abused a substance. The majority, 15.2

million, were dependent or abused alcohol, 3.9 million were dependent or abused both alcohol and drugs, and 3.1 million were dependent or abused both. Drug and alcohol use trends downward as people get older but for addicts use can increase as more of the substance is needed to generate a high. Unfortunately there is no information on substance abuse by profession.

Since alcohol is the most abused substance, research regarding alcohol abuse by eminent creative people will be reviewed first. This will include the extent of use, families of alcoholic creative people, effects of use, and experimental research.

Use of Alcohol by Eminent Creative People

Extent of Use Among Eminent Creative People

Alcohol and creativity have been linked by the fact that many eminent creators have been heavy users and alcoholics. **Table 1** is a partial list which is impressive because there are numerous eminent writers, artists, performers, and musicians.

The largest scale attempt to identify the level of alcoholism in eminent creative people was done by Arnold Ludwig, who in 1995 reviewed the lives of 1004 eminent people who had a biography reviewed in *The New York Times Book Review* between 1960 and 1990. He assessed alcohol dependence or abuse on the basis of physical problems, work interruption or poor performance, personal and interpersonal problems, and arrests. He found: "among eminent people 26% experience alcohol related problems during their lifetime, 23% of women and 27% of men." Creators in the arts were much more at risk:

Actors or directors, musical entertainers, sports figures, fiction writers, artists and poets (29% to 60%) have higher rates of alcohol dependence or abuse than natural scientists, soldiers, social scientists, social activists and social figures (3% to 10%). (1995: 133–134)

These results are considerably higher than the 7.7% rate of combined alcohol abuse and dependence of alcoholics in the United States. Men greatly outnumber women and in contrast

to eminent creators, rates of alcoholism declined with age rather than increased. Higher rates of alcoholism among creative artists, especially writers, have been found in a number of other studies. One study found that 30% of the Iowa workshop for creative writers had a problem with alcoholism at some point in their lives. Another study found that female writers had an alcoholism rate of 20% relative to a control group rate of 5%.

Albert Rothenberg pointed out that higher rates of alcoholism in the creative arts could be encouraged by the nature of the work, which is often isolating and allows the individual writer or painter to drink more easily. Alcoholism is found less frequently in scientific professions where personal vision is less important than producing objective data that can be replicated.

Cultural conditioning is an area which needs further investigation. It is obvious that alcohol and drug abuse is a serious problem in the entertainment business. High profile actors include Robin Williams, Mel Gibson, Ben Affleck, and Drew Barrymore. The list of rock and roll musicians include Elton John, Eric Clapton, Pete Townshend, Eminem, and Ringo Starr. Amy Winehouse wrote a song called Rehab and inevitably there is a group with that name. Unfortunately many people have not gotten to rehab, or rehab did not work, and the list of early deaths of highly talented individuals is a long one. Subcultures creating an atmosphere which encourages alcohol and drug use will be discussed later in this article.

Families of Alcoholic Creative People

Ludwig found 12.2% of the fathers and 2.4% of the mothers of eminent creative artists were alcoholic compared to 6.6% of the fathers and 0.5% of the mothers in other professions. Furthermore, 10.6% in the creative arts had alcoholic siblings compared to 6.3% of others. Other studies found that 11% of the writers had at least one alcoholic parent compared to 7% of the total sample. Examples of creative people who came from alcoholic families include Charlie Chaplin, Tennessee Williams, Orson Welles, and Truman Capote.

The coincidence of alcoholism and other addictions in families is confirmed by genetic research. Sarah Hartz and Laura Bieret stated:

Robust genetic associations have been found for alcohol dependence, nicotine dependence, and cocaine dependence. (2010: 107)

As genetic research becomes more sophisticated we may eventually be able to understand if there is a genetic link between substance abuse and specific creative talents.

There is a paucity of research looking at alcoholism in families. In a study on painters, the only characteristic which differentiated excessive drinkers from moderate drinkers was having the same profession as their father. In one case, the son of a successful father exhibited anxiety over competition with the father. In another case, the son pursued painting to satisfy his father's unfulfilled ambition "at the cost of inner development and constant strain."

Effects of Use

Physical Effects

Small doses of alcohol may help stimulate some aspects of brain function but alcohol is otherwise a depressant. *Encyclopaedia Britannica* online states that as more alcohol is consumed, an individual becomes more depressed, going on to sedation, stupor, and coma. The excitement phase exhibits the well-known signs of exhilaration, loss of socially expected restraints, loquaciousness, unexpected changes of mood, and occasionally uncontrolled emotional displays. This may result from an indirect effect of alcohol in suppressing the function of inhibitory brain centers rather than a direct stimulation of the manifest behavior.

Prolonged use of alcohol damages the health of many alcoholics. Consuming four drinks a day or more can cause high blood pressure, coronary heart disease and failure, and stroke. Prolonged alcohol use is also associated with brain damage and the development of neuropsychological disorders. Impairments may include deficits in short-term memory, disrupted cognitive and motor functioning, poor attention span, difficulties with problem-solving and learning new information, sexual dysfunction, and suppression of the immune system.

The lack of inhibition caused by drinking is directly linked to criminal behaviors, including physical violence and homicide. Legal problems as well as divorce also increase.

Alcoholism can cause death from cirrhosis of the liver and impaired motor ability relating in alcohol related fatalities in automobile accidents, falls, and drowning. High levels of alcohol are found in 36% of suicides.

Effect of Use by Eminent Creators

Some eminent creative people believed alcohol was a vital component in their success. The most common use was to overcome fear and anxiety. Aristophanes, in a play written in 424 BC, wryly commented on the benefits of alcohol: "When men drink, then they are rich and successful and win lawsuits and are happy and help their friends. Quickly, bring me a beaker of wine, so that I may wet my mind and say something clever." Dorothy Parker said, "Three highballs, and I think I'm Saint Francis of Assisi."

Other creative people drank to escape the difficulties of life. The sensitivity and awareness which made their work special also made them more prone to depression and a sense of isolation. In many cases, alcohol was used as a type of medication to dull the sharp edges of life. Tennessee

Williams seemed to be speaking for himself when he had one of his characters in *Cat on a Hot Tin Roof* say, "Mendacity is a system that we live in. Liquor is one way out an' death's the other."

In some cases, creative professions may be the only work an alcoholic could do. The individual has the freedom to drink and work as a writer or painter. Utrillo, according to Sandborn, was slightly below average in intelligence. His family kept him supplied with wine and painting supplies.

A sense that alcohol somehow contributed to their creativity (perhaps used as a justification for their drinking) helped demolish the long-term productivity or shortened the lives of many eminent creative people. Younger creative people still have the physical resilience to drink heavily and get their work done, but as they age it becomes more difficult, which is not surprising considering the physical effects of alcohol.

Of course, alcohol can deter productivity even when it is not used while an individual is working. Rothenberg defined three states of drinking for the writers he studied:

1. Early in their career, they only drink after work.
2. Drinking begins to occur during the day as the need for alcohol increases, which is the progression experienced by most alcoholics. In the case of writers, the loneliness of the job combined with the anxiety and uncertainty of the work can lead to a state of 'irritability.' Alcohol is used as a sedative which helps soothe frayed nerves.
3. The increased drinking results in a deterioration in the quality of the work.

Rothenberg cautioned that each case is individual and may be triggered by elements unconnected to writing such as genetics or family history. When the parent whom the writer lovingly and competitively identifies with is an alcoholic, then the dangers of alcoholism are particularly high. Examples include John Cheever and William Faulkner.

F. Scott Fitzgerald summed up the danger of drinking in his work and life: "First I take a drink. Then the drink takes a drink. Then the drink takes me."

Alcohol use peaked in 1980 and has been declining as awareness of the dangers of alcoholism and stricter drunk driving laws have been enforced. It will be interesting to see if the number of eminent alcoholic creators also declines.

Experimental Research

Results of research using noneminent subjects indicates that the perception that alcohol influences creativity is greater than any real benefit to creativity that alcohol may give. The drinking of alcohol may exaggerate an individual's self-assessment of his or her work. One study found that low doses of alcohol did not affect the quality of creative work, but subjects who believed they had taken alcohol *thought* their work was better. In another study, subjects who *thought* they had taken alcohol produced more creative combinations of wildflowers even if they had a placebo. This suggests that just thinking one has drunk alcohol may loosen some people's inhibitions.

A few researchers have attempted to determine if alcohol facilitates creative writing under laboratory conditions. There are indications that alcohol significantly increases the number

of words produced, confirming anecdotal accounts of writers who find alcohol an aid in producing work, but quantity does not necessarily equal quality.

One study measured the effect of alcohol on a control group, a placebo group, and an alcohol group during different phases of creativity. Moderate amounts of alcohol facilitated incubation and restitution in college students, while harming the preparation, illumination, and verification stages. The researchers tied this in to self-reports of professional writers indicating they used alcohol primarily during the incubation and restitution stages of writing. They also concluded that the difficulty of creative writing leads to increased drinking. Alcohol may reduce anxiety and tension for some writers, but there also appears to be a tendency for users to exaggerate the benefits, perhaps to justify its continued use. Because life circumstances are confounded with the propensity to use drugs, the causal relation of drugs to creativity remains uncertain. The fact that many creative people used alcohol moderately or heavily does not mean that alcohol *caused* creative solutions. None of these studies looked at how alcohol affects accomplished creative individuals under actual working conditions.

While many creative people have claimed that alcohol helped them, the truth of this statement in objective terms has not been determined. Ludwig concluded 9% of his sample had helped their creativity by using alcohol; however, he cautioned that the perception alcohol helps creative work could be exaggerated by the properties of alcohol. He pointed to John Cheever, Eugene O'Neill, and Jackson Pollock as examples of creative people who gave up alcohol and then did some of their best work.

Drug Use

Opium was used by doctors in Greece in 100 BC. In North America, drug use dates back to native tribes in the United States and Mexico who took mushrooms and peyote within the context of religious ceremonies. Coca leaves were used by natives as a part of social life, work, and worship for thousands of years in South America. These drugs were a part of the cultural fabric and have a genuine spiritual connotation for many practitioners.

Traditional and newer man-made prescription drugs have contributed to a situation where substance dependence and abuse have become widespread. The US Department of Health and Human Services Substance Abuse and Mental Health Services Administration survey mentioned in the introduction indicated that in 2008 4.2 million people representing 1.7% of the population were dependent on marijuana or hashish. 1.7 million on pain relievers, and 1.4 million cocaine. Hallucinogens, inhalants, and heroin had lower levels of use.

Concrete statistics on drug use among creative people is not available. Anecdotal evidence based on public disclosure indicates it is significant, but objective studies that delineate the relationship between creativity and drugs are difficult to execute.

Nevertheless it is clear that some creative professions participate in drug subcultures which vary according to the type of drug. J. Radenkova-Saeva (2008) defined drug subcultures as:

groups of people loosely united by a common understanding of the meaning and value (good or otherwise) of the incorporation into life of the drug in question. (p. 22)

These groups often form friendships that involve taking:

the drug together, possibly obeying certain rules of etiquette, to full-scale political movements for the reform of drug laws. The sum of these parts can be considered an individual drug's culture. (p. 22)

Next, some drugs will be reviewed in relation to what we know about its effects and culture. Many users take a variety of different drugs along with alcohol.

Opium and Heroin

Perhaps the oldest drug is opium which is produced using seeds from the opium poppy. Opiates include opium, morphine, and heroin which work on the brain and spinal cord lessening pain and creating a feeling of euphoria. Smoking opium did not come into vogue until the discovery of Indians smoking tobacco.

Symphony Fantastique by Hector Berlioz is an example of a classic work inspired by his opium use. The story is based on Berlioz's unrequited love for an Irish actress named Henrietta Smithson. Movements 4 and 5 occur after a young musician poisons himself in despair and experiences strange visions which are translated into his music. Smithson had left for London when Berlioz wrote the symphony but by the time it was performed she returned to Paris and attended it's opening by chance. Berlioz ended up captivating her heart and marrying her but sadly the marriage did not work out.

Charles Baudelaire, the French poet, and Alexander Dumas, belonged to The Club des Hashischins where hashish was taken every month at séances. Baudelaire clearly had addiction problems with alcohol and opium as well as hashish that may have contributed to his death. Coleridge is alleged to have written the *Kubla Kahn* under the influence of opium. Other famous opium users include Elizabeth Barrett Browning, Sir Walter Scott, and W. B. Yeats.

Escaping from the confines of life was used as an explanation for his opium use by Cocteau. Baudelaire wrote:

Opium magnifies that which is limitless
Lengthens the unlimited,
Makes time deeper, hollows out voluptuousness
And with dark, gloomy pleasure
Fills the soul beyond capacity (quoted in Largo, 2008: 24)

By the twentieth century stronger forms of opium including heroin had been concocted. A heroin subculture became prevalent in the jazz community from the 1930s to the 1960s. Talented musicians such as Billie Holliday, Charlie 'Bird' Parker, and Chet Baker's deaths were related to heroin. Others such as Miles Davis whose album *Birth of The Cool* is considered the best in history by many as well as Ray Charles also used heroin. Rock stars Janis Joplin, Jim Morrison, and Kurt Cobain died from heroin or morphine overdoses along with many others. Comics Lenny Bruce, John Belushi, and John Candy also died of drug overdoses. Lenny Bruce said "I'll die young but, it's like kissing God."

Cocaine and Crack Cocaine

Cocaine is a concentrated form of coca leaves which is usually snorted and absorbed quickly. It creates a very intense high. Eventually cocaine addiction can lead to severe problems in the nasal cavity, along with paranoia and insomnia.

Sigmund Freud wrote a paper called *Uber Cola* in which he experimented on himself a dozen times and noted the 'exhilaration and lasting euphoria.' He later changed his mind about benefits when a friend died from an overdose. Other prominent creative individuals who used cocaine include Elton John, Stevie Nicks, and Isadora Duncan.

Dr Jekyll and Mr Hyde is thought to be at least subconsciously about drug use and personality change. Robert Louis Stevenson was a cocaine addict who allegedly wrote the book while using. Sir Arthur Conan Doyle depicted the destructive aspects of cocaine in Sherlock Holmes who became addicted.

Nelson Algren's *Man with The Golden Arm* about a morphine addict won the National Book Award which was made into a movie starring Frank Sinatra.

Cannabis and Hashish

Cannabis (also known as marijuana, weed, pot, etc.), are the buds and leaves of the Indian hemp plant. THC is a psychoactive chemical which causes relaxation and reduced short-term memory. Continued use can result in increased anxiety and paranoia in some individuals. It is a milder form of intoxicant than hashish which is a hardened form of cannabis that is eight times stronger. Cannabis was used as early as 3000 BC in Egypt.

Louis Armstrong started smoking in the 1920s and used it all his life on a daily basis. He even planned to write a book about it called *Gage* but his manager thought it was a bad idea and the manuscript was put away. Armstrong was arrested once for possession but never went to jail. Actor Robert Mitchum was not as lucky – he spent two months in the Los Angeles county jail for possession.

In the 1960s and 1970s marijuana became a commonly used drug as it still is today. The pot subculture includes hundreds of pop songs that praise grass. Stoner movies became a minor genre which included *Up in Smoke* starring Cheech and Chong, *Pineapple Express* and *Harold and Kumar go to White Castle*. Sean Penn became a star playing a stoner in *Fast Times at Ridgemont High*.

Today some creative individuals such as comic Bill Maher and Willie Nelson publicly admit smoking cannabis regularly. It has reached acceptance to the point that President Barack Obama mentioned he smoked grass in his autobiography. Richard Branson, the Chairman of Virgin Airlines and Mayor Michael Bloomberg of New York also publicly disclosed they had used grass.

Lysergic Acid Diethylamide

Albert Hoffman, a research chemist, had a hunch that lysergic acid diethylamide (LSD) might have some special properties in 1943. In his book, *LSD: My Problem Child*, he described what happened when he was preparing some concentrated LSD for the first time. He suddenly became dizzy and felt he had to go home and lie down. In the next two hours he experienced intense colors, fantastic pictures and a pleasant intoxication. He knew he was on to something special and likened his

recognition to Louis Pasteur who said "luck only happens to those who are prepared."

There was immediate interest in researching the power of LSD by psychiatrists working with schizophrenia, alcoholism, and patients in therapy. Oscar Janiger completed an 8½ year study in Los Angeles which ended in 1962. He eventually recruited 930 individuals; initially half were in psychotherapy and half were in the general population. So many professional artists volunteered that he added a substudy. Janiger discovered artists:

somehow found a way to harness the LSD state to the creation of art and were able to increasingly control the physical expression of their subjective experiences. (de Rios & Janiger, 2003: 24)

According to de Rios and Janiger:

The heightened aesthetic sensibilities of the psychedelic experience clearly broaden the individual's subjective sensitivities. In the great majority of reports we see instances in which moral values were affirmed, emotional conflicts were resolved, and participants appear to have been better able to cope with human predicaments. (p. 42)

There was also a strong spiritual component – 24% of participants experienced "a mystical or spiritual encounter" (p. 115). No negative effects were reported. One of the subjects, movie star Clark Gable, gave an interview in which he said he had a psychological breakthrough with the help of LSD.

In 1963 LSD moved out of the lab and into the popular culture with a huge splash as Timothy Leary and Richard Alpert were thrown out of Harvard for advocating LSD use for everybody. By 1965 it was illegal in California but the genie was out of the bottle. Acid helped inspire the hippie movement which began with the summer of love in San Francisco and continues in spirit today at the Burning Man festival.

Musicians wrote and performed in a short-lived genre in the 1960s called psychedelic rock which was sometimes referred to as acid rock. Beatles songs included *Day Tripper*, *Tomorrow Never Knows*, and *Norwegian Wood*. Jerry Garcia and The Grateful Dead, The Jimi Hendrix Experience, Pink Floyd, and Jefferson Airplane were part of psychedelic rock. Jim Morrison named his band The Doors after the *The Doors of Perception*, Aldous Huxley's book about mescaline. Brian Wilson of the Beach Boys took LSD which probably influenced *Good Vibrations*.

Ken Kesey toured the country in a colorful old bus taking acid and writing about his experiences. Tom Wolfe's *The Electric Kool-Aid Acid Test* was about Kesey. LSD inspired a minor art movement with a recognizable style. Peter Max claimed he never took drugs but his extremely popular paintings were considered psychedelic art.

Prescription Drugs

Prescription drugs including painkillers, sedatives and tranquilizers, and stimulants have been abused for many years. Drugs such as Valium, Xanax, Vicodin, OxyContin, and methadone show up frequently in ER emergency situations. In a National Survey more than six million Americans over the age of 12 stated they used prescription drugs for nonmedical uses.

Prescription drugs have been implicated in the deaths of Marilyn Monroe, Jimi Hendrix, Elvis Presley, Heath Ledger, and Michael Jackson among others. Celebrities may be more at risk for prescription drug overdose because they have easier

access from Dr Feelgoods who in some cases are on their payroll. Prescription drugs have not inspired many creative products.

Summary and Conclusions

Theories about why the use of alcohol and drugs are more prevalent in creative professions include:

1. *Genetic predisposition*: A higher percentage of fathers, mothers, and siblings of eminent creative people were alcoholics.
2. *Self-medication*: More people have affective mental illness so they may be self medicating with alcohol and drugs.
3. *Opportunity*: Writers, artists, and composers often work alone so they can drink or use drugs more often without anybody knowing about it.
4. *Subculture*: Performers live in a subculture where alcohol and drugs are easily available and are a part of the culture. Previous stars who died dramatically and publicly from use of alcohol and drugs may be idolized and emulated by the next generation.
5. *The difficulty of the work*: Creative work is tough and uncertain, and the road to success is paved with disappointment and rejection. Creative artists suffer blocks at times. Alcohol and drugs may provide escape from the pain.
6. *Stress*: Success brings its own pressure. Creators often feel they must match or exceed their previous work. Simonton proposed alcohol use may provide the user with a self-handicap, a convenient excuse that justifies failure. For performers such as musicians, comedians, and actors, the pressure of having to be at the top of your game because the stakes are so high can encourage some creative people, especially live entertainers, to start taking drugs and alcohol to:

overcome their performance anxieties, to loosen their inhibitions and to wind down so they can sleep after being energized by their performances. (Ludwig, 1995: 136–137)

7. *As an aid*: Some creative people have stated they felt alcohol helped their work, especially in overcoming anxiety during the initial stages of creation.
8. *Widening consciousness*: The idea, reinforced by some creative individuals, that they are using alcohol and particularly drugs in an attempt to widen their consciousness and seek new perspectives.
9. *Spirituality*: The explanation that some creative people are seeking a spiritual experience through the use of drugs.

The fact that so many influential creative people have been drug users and abusers inevitably led to their inclusion of songs, books and films that talk about drugs. In the case of musicians, there may also be an element of trying to be a part of the culture of their younger audience as they found themselves aging. Whether these works inspired drug and alcohol use among fans is still not proven.

The strength of the drug culture in popular legend can also be measured by the hundreds of films dealing with drugs both from an individual use and dealer standpoint. Dying from drugs seems to inspire film-makers imagination with biographies already made of many of the stars already mentioned including Billie Holiday, Marilyn Monroe, Jim Morrison, Janis Joplin, Charlie Parker, and Lenny Bruce.

Contemporary authors such as Carrie Fisher in *Postcards From The Edge* and Stephen King in *On Writing* wrote frankly about their drug and alcohol problems. King said:

The idea that creative endeavor and substances are entwined is one of the great pop-intellectual myths of our times. (in Hyde and Zanetti, 2002: 210)

He acknowledged that:

Creative people do probably run a risk of alcoholism and addiction more than those in some other jobs, but so what? We all look pretty much the same when we're puking in the gutter.

The number of variables involved leave the relationship between creativity and alcohol with many unanswered questions. Far more work needs to be done to understand the physiological effects of using drugs as well as the psychological dynamic. Innovative methods are needed to research this challenging field.

Suicide

D Lester, The Richard Stockton College of New Jersey, Pomona, NJ, USA
K Kryszynska, University of Queensland, Brisbane, QLD, Australia

© 2011 Elsevier Inc. All rights reserved.

This article is a revision of the previous edition article by David Lester, volume 2, pp. 585–591, © 1999, Elsevier Inc.

Glossary

Attempted suicide Suicidal actions that the person survives. This is also called parasuicide and deliberate self-injury by some suicidologists.

Bipolar affective disorder A severe psychiatric disorder characterized by periods of extreme depression and extreme excitement known as mania.

Completed suicide Suicidal actions that result in the death of the person.

Gifted people People who typically score high on tests of intelligence.

Suicidal behavior encompasses a wide range of behaviors, including both fatal suicidal behavior (commonly called completed suicide) and nonfatal suicidal behavior (including attempted suicide, suicidal threats, and suicidal ideation). In addition, some scholars view other forms of self-destructive behavior as suicidal in nature. Alcohol and drug abuse have been viewed as chronic suicidal behavior and behavior such as self-mutilation and self-castration as focal suicidal behavior. This article focuses on fatal and nonfatal suicidal behavior and creativity. A discussion of suicidal behavior in creative people is intimately related to the issue of psychiatric disorder because in general the majority of suicidal individuals have a diagnosable psychiatric disorder, over 90% in some studies. People who have been psychiatric inpatients have higher suicide rates subsequently than people who have been psychiatric outpatients who, in turn, have higher suicide rates than the general population. Suicide is especially common in those with mood disorders and schizophrenic disorders, disorders which are also associated with creativity.

Is Suicidal Behavior More Common in Creative People?

Anecdotally, it has often been claimed that creative individuals are at high risk for suicide. For example, writers in the former Soviet Union, Great Britain, Japan, and the United States committed suicide in large numbers during the twentieth century. The suicides of Soviet Union writers have been attributed to the oppressive Soviet regime and the suicides of British writers to poor sales and high taxes. It is more likely, however, that it is the profession of writing rather than local conditions that leads to this apparently high suicide rate in writers.

Estimates of the percentage of deaths from suicide in eminent people range from 0.3% to 13.3% with a median of 2.9%. The percentage seems to be higher among literary figures. A study of 1000 eminent people of the twentieth century found that a suicidal death was more likely among artistic individuals in general (especially poets) and less common among public officials, explorers, architects, and social figures.

Attempted suicide was also more common among artistic individuals.

Artists as an occupational group in general and certain subgroups of artists in particular, for instance writers and poets as well as female artists, have higher suicide rates. Steven Stack in an analysis of suicide rates among occupational groups in the US (based on the standard federal occupational codes) found that artists, along with doctors, dentists, mathematicians, and scientists, were an occupational group with an increased suicide risk, even after controlling for age, gender, marital status, and race. Artists were twice as likely to die from suicide than the rest of the working-age population, probably due to high prevalence of psychiatric disorders and high occupational stress linked to their profession. In the early 1990s, the suicide rate in the United States for artists in general (33 suicides per 100 000 artists) was almost three times the national average, and suicide rates for subcategories of artists ranged from 23 per 100 000 for actors and directors to 44 per 100 000 for visual artists, such as painters and sculptors.

Antonio Preti and Paola Miotto studied over 3000 internationally eminent persons in the visual and literary arts such as writers, poets, playwrights, painters, sculptors, and architects and found 59 suicides in that group. The prevalence of suicide was particularly high among poets and writers, and in female artists (a rate of 4.3%; compared to 1.75% among male artists). Female poets were at the highest risk: six out of 42 female poets included in the sample died from suicide. Self-destructive behavior in this group of eminent artists was not limited to suicide; there were several deaths directly related to alcohol abuse, for example, Dylan Thomas and Edgar Allan Poe.

Felix Post, in his study of psychopathology and creativity among 291 world-famous men, found five cases of completed suicide (Ernest Hemingway, Ludwig Boltzmann, Vincent van Gogh, Adolf Hitler, and Pyotr Tchaikovsky) and eight suicide attempts in writers (16.0% of the sample), five among composers (9.6%), four in artists (8.3%), three among scientists (6.7%), and two in the subgroup of scholars and thinkers (4.0%); altogether 22 suicide attempts. There was no suicide attempt recorded among eminent politicians.

Research on Writers

Following an earlier study on almost three hundred world-famous men which showed high levels of alcoholism and pathological personality traits in creative writers and visual artists, Felix Post looked at a group of 100 eminent British and American writers divided into subgroups of poets, prose fiction writers, and playwrights. There were significant differences among the three groups on several measures of psychopathology, such as high levels of alcoholism and affective illness in playwrights and prose writers and a high prevalence of bipolar affective disorder in poets. There were eight cases of suicide: six poets (John Berryman, Hart Crane, John Davidson, Randall Jarrell, Vachel Lindsay, and T. O'Hare) and two prose writers (Ernest Hemingway and Jack London), and seven suicide attempts. The attempts, usually closely related to depression, were found in the life history of three novelists (Joseph Conrad, Scott Fitzgerald, and Evelyn Waugh), three poets, who also wrote prose (Robert Graves, Walter Savage Landor, and Edgar Allan Poe) and one playwright (Eugene O'Neill).

Nancy Andreasen compared 30 creative writers at the University of Iowa workshops with 30 controls, and found that two of the writers and none of the controls committed suicide, while 3% of the primary relatives of the writers committed suicide versus none of the relatives of the controls.

David Lester examined the lives of 13 famous novelists and poets who killed themselves. He noted that two of them had fathers who completed suicide. Three others lost parents during childhood while another lost the grandmother who had raised him. Two others lost siblings. Six of the writers had engaged in prior nonfatal suicidal acts. Five were judged to be alcohol abusers, three had been hospitalized in order to receive electroconvulsive therapy, and seven were judged to have suffered from a mood disorder. Only one writer was judged to be schizophrenic, although five showed signs of paranoia. Problems associated with their writing appeared to be present in the majority of them and may have contributed to their suicides.

Research on Visual Artists and Musicians

A list of painters and visual artists who died by suicide is extensive. Fred Cutter compiled a list of 41 artists from the mid-sixteenth century to 1975, and Kay Jamison provided names of 14 artists who died by suicide (including Vincent van Gogh, Arshile Gorky, and Mark Rothko) and three who attempted to take their lives (Paul Gauguin, George Innes, and Dante Gabriel Rossetti). Karolina Kryszynska identified over 100 Western artists who died by suicide over the last 500 years. Joseph Schildkraut and his colleagues found two suicide deaths (Arshille Gorky and Mark Rothko), two instances of paternal suicide (Philip Guston and Franz Kline) and two single vehicle accidents (Jackson Pollock and David Smith) in a group of 15 Abstract Expressionist artists of the New York School. Schildkraut's study also found a strikingly high prevalence of mental disorders, mostly depression and other depressive disorders, as well as alcohol abuse among the artists. Overall, in comparison to men in the general population, the Abstract Expressionists were three times more likely to die before they reached the age of 60 (almost half of them died before that age)

and the main cause of death in that group was heart disease, followed by suicide combined with accidental death. The high premature mortality in this group might be related to high prevalence of depression and negative childhood experiences (i.e., absence or early loss of a father).

Antonio Preti and his colleagues compared over 4000 eminent nineteenth and twentieth century artists representing three types of artistic creativity: visual (sculptors, architects, and painters), linguistic (dramaturgians, writers, and poets) and musical (i.e., opera singers, composers and instrumentalists). They found 63 suicides in the overall sample, including 53 in literary artists (comprising 2.3% of the sample), six in visual artists (0.7%), and 4 among musicians (0.2%). Among musicians, there were no suicides in instrumentalists, while one opera singer and three composers died from suicide. Preti suggested several protective mechanisms against suicide operating among musicians as compared to other categories of artists: higher social and financial status, the necessity to acquire high levels of technical skills which may be incompatible with the severe mental or medical disorders that are linked with risk of suicide, and the nature of the work, including the need to interact with others and to develop relevant social and relational skills. Working with music may also have a specific therapeutic effect: music may involve artistic material closer related to the 'self' and more 'healing' than the graphic or verbal symbols used by visual and literary artists.

Despite Preti's findings on the low incidence of suicide among musicians, several classical composers killed themselves or attempted suicide, mostly in the context of severe mental disorders, such as depression, although in some cases it is not possible to provide a reliable psychiatric diagnosis based upon available biographical data. An English baroque composer Jeremiah Clarke (1670–1707) and an Anglo-Welsh composer and music critic Philip Haseltine, a.k.a. Peter Warlock (1894–1930), died by suicide, and it has been speculated that a Russian Romantic composer Pyotr Tchaikovsky (1840–1893) took his own life. Suicide attempts by drowning were made by Hugo Wolf (1860–1903), an Austrian composer and Robert Schumann (1810–1856), a German composer and an influential music critic. Both of them died in psychiatric hospitals.

Geoffrey Wills looked at mental health issues in a group of 40 eminent jazz musicians from the classic era of American modern jazz 1945–1960 ('bebop'). He found two suicides in this group: trombonist Frank Rosolino, who died at the age of 52 and shot his two sons, and trombonist J. J. Johnson who committed suicide at 77 after months of severe physical illness. There were many cases of heroin-related disorders in the jazz musicians: half of them were addicted to heroin at some time during their lives (which was most probably related to the anti-establishment character of both drug use and jazz music at the time). There was also a high prevalence of alcohol-related disorders and mood disorders.

Creative Women

Lester also examined the lives and deaths of six creative women who killed themselves, comparing them with six creative women who died of natural deaths and with six creative men

who killed themselves. For the women, the suicides and natural deaths did not differ in birth order, substance abuse, or loss of parents early in life, but the suicides were younger at the time of their death. The suicides were more likely to be divorced or separated at the time of their death. Not surprisingly, more of the suicides had made nonfatal suicidal actions in the past. The most striking finding, however, was the presence of psychiatric disturbance among the suicides. Five of the six suicides had a mood disorder or depressed mood versus none of the natural deaths.

Comparing the suicidal women and men, Lester found no differences in age at death, prior suicide attempts, or birth order. Like the women, the majority of the men were experiencing marital problems (separation or marital discord). The men seemed to have more experience of early loss than the women, though the numbers in the sample were small. Both the men and women had a high incidence of mood disorders, but the men appeared to have a greater incidence of alcohol abuse. As with the women, problems with their creative work was common.

Suicide and Affective Disorder

Kay Jamison documented the association between manic-depressive disorder, suicide, and creativity. In a sample of 36 British and Irish poets born between 1705 and 1805, she found that 27 had clear signs of depressive and psychotic disorders and two had committed suicide, both manic-depressives.

Rather than the depression and mania simply increasing the risk of suicide in creative people, the greater incidence of suicide may be a result of a greater lack of impulse control since recent research has indicated that serotonergic dysfunction in the central nervous system may lead to impulsive behavior rather than depressive syndromes.

Attitudes Toward Suicide

George Domino compared samples of creative and noncreative college students. The two groups were similar in age, gender, college major, and vocabulary level, but creative students performed significantly better on objective tests of creativity. When given an inventory to measure attitudes toward suicide, the creative students differed significantly from the noncreative students on seven of the eight scales. The creative students perceived suicide as more associated with mental illness and less as a cry for help, felt more strongly that people have a right to die, disagreed more that a lack of religious values was associated with suicidal behavior, perceived suicide as both a more normal behavior and as a greater reflection of aggression, and judged suicide to be less of a moral evil. Domino's results indicate that creative students perceive suicide as a more readily available behavior and efficacious solution to life's problems.

Are Suicidal People Creative?

Several studies have explored whether suicidal people are good at solving problems. The general conclusion seems to be that they are impaired in their problem-solving skills.

Suicidal Behavior in the Gifted

Gifted people are not necessarily creative, although they may be. Typically giftedness is measured by intelligence tests, which penalize creative responses by scoring them as incorrect. However, there is some overlap between the gifted and the creative, and research on suicidal behavior in the gifted is of interest.

The academically gifted have been thought to be more susceptible to depression and suicide, not only because of the typical suicidogenic risk factors (such as psychiatric disturbance, drug and alcohol abuse, and dysfunctional family backgrounds), but also because of factors associated with their giftedness.

1. Gifted adolescents may be prone to perfectionism, a trait that has been linked to suicide.
2. They may be more sensitive to the world in general and to the stressors encountered in adolescent life.
3. They may have greater problems adjusting to the school system, which is not usually designed to meet the needs of gifted and creative students and often lacks appropriate educational resources and support for their abilities. As a result they may feel bored and alienated.
4. They feel more pressure from others to achieve, which may result in unrealistic expectations for themselves.
5. They may feel frustrated by their impotence to produce real-world change.
6. They may find themselves more socially isolated and alienated, partly because they prefer solitary and single-friend activities, which may result in poor relationships with their academically average peers.
7. Their development may be more uneven, particularly their emotional development, which often lags behind their intellectual development.

Methodologically sound studies of suicidal ideation and behavior in gifted children and adolescents have not found that the incidence of suicidal behavior is greater than among average people. At the college level, however, there is some evidence to suggest that suicide rates are higher at the most prestigious universities.

One of the most important samples of gifted children studied is that created by Lewis Terman in California in 1921, consisting of 1528 children with a mean age of 9.7 years and an IQ score of over 140. By 1987, 25 men and nine women had killed themselves. The proportion of deaths due to suicide up to 1987 was 8.7% for the men and 5.2% for the women. The strongest predictor of suicide in this sample appears to be poor mental health, although the suicides have more often lost their fathers as children, had problems with alcohol abuse, experienced more stress in their family of origin, and had worse physical health.

The Role of Other Factors

It has been noted that there is a high incidence of alcohol abuse in creative individuals, such as artists and writers. This association may mean that alcohol intoxication (and perhaps abuse) increases creativity (perhaps by providing inspiration), that the creative lifestyle makes alcohol abuse more likely (alcoholism

may be a disease of loners and individualistic individuals), or that some third factor (childhood experiences or psychosocial influences) increases the likelihood of both creativity and alcohol abuse. Regarding the first possibility, there is some research evidence indicating, for example, that alcohol intoxication does not increase creativity in average individuals. Whatever the reasons, the association of creativity and alcohol abuse does provide a possible explanation for the association between creativity and suicidal behavior because alcohol abuse has been shown clearly to be associated with the likelihood of both fatal and nonfatal suicidal behavior.

Other psychological and social factors may increase suicide risk in creative people. Stack proposed a multicausal model of occupation-related suicide risk encompassing demographic factors (e.g., gender and age of individuals usually engaged in a profession), internal occupational stress, psychiatric morbidity (i.e., the extent to which a profession may attract or retain individuals at psychiatric risk for suicide), and opportunity factors (i.e., access to means of suicide). In the case of the artistic professions, the high suicide rate seems to be related to high levels of occupational stress, especially the risk of rejection of personal products, and psychiatric morbidity, especially affective disorders. For instance, several occupational stress factors operated among American jazz musicians mentioned earlier which might have increased their vulnerability to mental health problems: racial issues, low wages, extensive touring, and the easy availability of drugs (especially heroin), alcohol and casual sex.

Sensation-seeking or the tendency to seek novel, varied, complex, and intense sensations and experiences and the willingness to take risks for the sake of such experiences is a personality trait linked to borderline and antisocial personality disorders, as well as to creativity via a preference for complexity and abstraction in art and a tendency for divergent thinking. It may also predispose creative individuals to disinhibition and thrill and adventure seeking: social drinking, experimentation with drugs, and a liking for parties, casual sex, and other risk-taking, impulsive, and self-destructive behaviors which, in extreme cases, may lead to suicide.

Treatment

Kay Jamison, Nancy Andreasen, and Ira Glick pointed out that although mood disorders can be counterproductive and may disrupt creative process, sometimes euphoria and increased energy levels linked to hypomanic or manic states may support and nourish creativity. Consequently, treatment of bipolar disorder in creative individuals presents particular ethical and clinical challenges. Does the patient feel better or worse while taking medication? Is creativity enhanced or decreased by the medication? They suggested that a responsible clinician working with bipolar creative patients should simultaneously ensure assessment and amelioration of symptoms of the disorder (suicide risk in particular), normalization of mood cycles, and maintenance of creativity cycles which may (or may not) be associated with mood cycles. In order to achieve such goals, both overtreatment and undertreatment should be avoided. With the correct psychopharmacological treatment of bipolar disorder, the gains outweigh the potential negative side effects and ameliorate the risk of suicide.

Mogens Shou looked at artistic productivity in a group of 24 artists suffering from manic-depressive disorder who were undergoing prophylactic lithium treatment. In this group, the lithium treatment significantly attenuated or prevented recurrences of the illness, and half of the artists reported increased artistic productivity, six unaltered productivity and six lowered productivity during the treatment. Shou concluded that the effects of lithium on creativity are dependent upon several factors, such as the type and severity of the illness, the sensitivity of an individual, and his or her habits of productively utilizing manic episodes.

Andrew Slaby argued for the early recognition and treatment of depressive disorders in creative people in order to decrease their suicidal risk. He stated that electroconvulsive therapy (ECT) and medications were useful in this regard and claimed that creativity is not affected by these treatments. However, although hard data are not available, anecdotal evidence suggests that these approaches may not be the best. Both Anne Sexton and Abbie Hoffman were diagnosed as having bipolar affective disorders and given lithium. Both disliked the side effects of the medication so much that they stopped taking it, and both completed suicide. Sexton, in particular, found that the lithium affected her ability to write poetry. Ernest Hemingway tried to commit suicide while being taken to the Mayo Clinic for the second course of ECT and killed himself the day after his release. In those days, psychiatrists suppressed the knowledge that ECT led to memory loss (sometimes permanent), and memory loss may have contributed to Hemingway's motivation to kill himself.

Slaby also urged that society take pains to reduce the stigma of being different, including being creative, bright, or sensitive. Although this is desirable, it is far from clear how society can remove this stigma.

Does Creative Writing Help Suicidal People?

Is writing therapeutic for creative writers or is it a stressor that contributes to their psychological disturbance? Although there may be merit in both positions, David Lester and Rina Terry argued that writing poetry can be useful with suicidal clients. Writing poems per se may not be helpful to the client, but the revision of the initial drafts of poems may be therapeutically useful. Revising poems may serve a similar function for clients as the journal assignments devised by cognitive therapists, which give the clients intellectual control over their emotions and distance from the traumatic memories. The researchers illustrated their thesis with Anne Sexton's life and suicidal death. Plath's life and death can also be used to illustrate this thesis.

Sexton revised her poems extensively and, in the process of revision, had to concentrate on form rather than content. This allows for both the action that therapists deem to be therapeutic and the distancing of the self from one's problems. Because Sexton ultimately chose the moment of her death, one should not discount the therapeutic help her writing afforded her. Anne Sexton illustrates the dialectic in poetry as therapy, between expression and catharsis on the one hand and cognitive control on the other. Sexton, as long as she was able to stay psychiatrically stable, applied the craft of poetry to her creative

productions. Both Sexton and Martin Orne, her first therapist, believed that her poetry had helped her recover. Only toward the end of her life, as her ability to craft her poems declined, did her mental stability dissipate.

Interestingly, Sexton showed manic trends prior to her suicide. She would write poems furiously, poems with more emotional expression and less poetic crafting. Rather than arguing that writing poetry contributed in part to her suicide, it makes much more sense to say that, in her final breakdown, poetry was no longer able to help her deal with the intrapsychic conflicts as it had in the past. As her inner turmoil increased, she wrote feverishly, almost like a safety valve letting out the steam under pressure in a boiler, but to no avail. The pressure was building up faster than she could release it.

But this final failure of the craft of poetry to keep Anne Sexton alive does not signify total failure. She was an outstanding poet and functioned quite well given her affective disorder. The craft of poetry may have kept her alive for many years after her self-destructive impulses first manifested themselves and so signifies success.

Suicide as Subject of Creativity

In a comprehensive review of the iconography of suicide, Cutter identified six self-injury themes prevalent in the Western art after the Renaissance (i.e., after 1350). The heroic theme (1484–1844) presented suicide as a rational and reasonable solution to contemporary dilemmas and a good behavior affirmative of virtue. The viewers' reaction was admiration for the hero or the heroine, and they were encouraged to follow this virtuous example. This theme was based on historical or mythological accounts of suicide in the context of loss of a lover and such values as patriotism, self-sacrifice, devotion to ethics, honor, and dignity. The theme of suicide as a stigmatized act (1660–1854) seems to be an opposite of the heroic theme. However, both coexisted quite comfortably for almost two centuries. The stigmatized suicide was conceptualized, in line with the Church's view of suicide as a mortal sin, as an evil end befitting an evil life motivated by a pursuit of immoral goals. The intended reaction of viewers was rejection and contempt. Good examples of the genre are found in the eighteenth and nineteenth century British art by William Hogarth, Thomas Rowlandson, and William Powell Frith.

The advent of the irrational theme (1827–1880) followed the Industrial Revolution and the changing conceptualization of mental illness, especially the consideration of social and psychological factors in its etiology and in the treatment of psychiatric patients. These changes resulted in the adoption of a more neutral and relative moral position towards suicide, reducing the stigma, and placed emphasis on the irrationality of the act, now viewed as an unreasonable means to a desired end. The viewers' reaction was sympathy or pity towards the victim rather than condemnation. Examples of the irrational suicide theme in the arts include paintings of the drowning Ophelia.

Representations of suicide in twentieth century art can be grouped into three partly overlapping themes: the depressive theme (1887–1927), the ambivalent theme (1930–1961), and the theme of suicide as a 'cry for help' (1938–1967).

The depressive theme presented suicide in a morally neutral manner and considered apathy as the main motivation behind the act. The viewers' reaction was a feeling of regret, sadness, and pity. The emphasis was put on the sadness of suicide victims, their lack of energy and lack of enthusiasm for life. The other two themes presented suicide in a morally neutral manner and viewed the motivation behind the death either as inexplicable (ambivalent theme) or obscure ('cry for help'). The ambivalent theme stressed the shock value of the act, evoking mixed reactions in viewers and drawing their attention to the painful sense of unhappiness experienced by the suicides and their ambivalent wish to live combined with the desire to die. Suicide is presented as a morally neutral act with obscure motivation, evoking a feeling of confusion in the viewers and demands their attention.

Visual representations of suicide can also be found in Asian art and in Indian cultures from Mexico and South America. For example, scenes of ritual self-disembowelment (*seppuku*) and lovers' suicide (*shinjū*) were frequent in Japanese *ukiyo-e* paintings (*uki* – floating, *yo* – world, *e* – pictures: 'pictures of the floating world'), woodblock prints, and book illustrations showing life in the great urban centers in the Edo or Kokugawa period (1615–1868). In Indian art, the self-burning of the goddess Sati, Shiva's wife, and other images of the Vedic practice of self-immolation of a widow on her deceased husband's funeral pyre (*suttee* or *sati*) can be found frequently. Ixtab, a Mayan goddess of suicide, is represented in an image of a deceased woman with a rope around her neck in an ancient book of the Yucatecan Maya in Chichén Itzá, the *Dresden Codex* (*Codex Dresdensis*, eleventh to twelfth century).

Suicide was frequently used as a dramatic ploy by William Shakespeare. In his 15 tragedies Larry Kirkland found 21 suicides: 13 definite (e.g., four suicides in 'Antony and Cleopatra' and four in 'Julius Caesar') and eight possible suicides, for instance Lady Macbeth in 'Macbeth.' Suicide in Shakespeare's tragedies was often a release from suffering and an escape from an impending misfortune and, despite a negative view of suicide and its victims propagated by the Church and the legal system in England at the time, there was an attitude of acceptance and even glorification of such a death in some of his works.

In the nineteenth century opera, suicide along with tuberculosis was a popular ploy to provide a suitably dramatic ending to a story with a dying character giving detailed reasons for her or his decision in a (long) song between the act and the death. A review of over 300 opera plots revealed 77 suicides, including seven cases of murder-suicide and 12 suicide attempts. For instance, in Giacomo Puccini's 12 operas composed between 1884 and 1924 there are four suicides: Tosca, Madam Butterfly, Suor Angelica, and Turandot. The conceptualization of opera suicides has changed over time: from the seventeenth and eighteenth century notion of a 'heroic suicide' often shown in an ancient Greco-Roman setting (e.g., Purcell's 'Dido and Aeneas') to nineteenth century 'romantic suicide' (e.g., Wagner's 'Tristan and Isolde') and a 'realistic suicide' related to mental illness and distress. Contrary to epidemiological data, the majority of opera suicides are committed by women (all Puccini's suicides are young women!) and end in death; in the general population, the attempts greatly outnumber completions, and male suicide rates are higher than female.

Operatic attempts at suicide are usually presented as an instrumental gesture with an appeal motive, for instance in Mozart's 'Cosi fan tutte.'

Suicide Imitation and Contagion

Interesting questions arise regarding the impact of suicide-related creative products, such as plays, music, or books on suicidal behavior of the audience. Could there be imitative suicides? Could people who are attracted to such artistic products be at an increased risk of suicide themselves? Does the audience imitate suicides of creative people they admire?

The phenomenon in which a book, play, song, or film provokes a number of people in the community to commit suicide is commonly called the Werther Effect after the publication of Goethe's 'The Sorrows of Young Werther' in 1774, which purportedly led to young lovers committing suicide in imitation. According to anecdotal evidence, there have been other such 'epidemics,' such as the rash of suicides in young Jewish females after the publication of Otto Weininger's 'Sex and Character' in 1903 and an alleged increase in suicides in the 1930s related to probably the best known song concerning suicide, 'Gloomy Sunday,' the 'Hungarian suicide song.' An earlier recorded epidemic occurred in the early 1700s in Japan in relation to kabuki plays, often presenting thwarted love with the suicides of the lovers as a common plot. These double suicides (*shinju*) presented on stage were imitated by many young people, leading to an epidemic of suicides. It is interesting that an epidemic of double suicides has never been reported after Shakespeare's 'Romeo and Juliet' was first performed. Perhaps national character or the social and religious prohibition of suicide plays a role in the appearance of contagious suicide.

Steven Stack conducted a series of studies on the relationship between suicide and preference for music which frequently expresses suicide-related themes such as honor, hopelessness, and alienation – opera, heavy metal, country and western music, and blues music. He found a higher acceptance for suicide related to dishonor (a frequent opera topic) in opera fans than in nonfans. However, opera fans were not more accepting of suicide related to other motives, such as terminal illness or being tired of living. An accepting attitude towards suicide was also found among heavy metal fans, and this relationship was mediated by their lower levels of religiosity. Low religiosity was positively correlated with suicide acceptance among fans of blues music, but there was no significant difference between blues fans and nonfans in levels of suicide acceptability. Stack also found that the greater the airtime devoted to country music in 49 metropolitan areas of the United States, the higher was the suicide rate among the white population (an effect independent of poverty, gun availability, divorce, and southernness), while the per capita subscription to heavy metal magazines was associated with youth suicide rates in 50 states. It is still unclear, however, whether individuals at risk of suicide or accepting of such behavior are attracted to suicide-related music and lyrics or whether such types of art may increase suicide acceptability and risk in vulnerable people.

Suicides of people considered celebrities may be linked to increased suicide rates in members of the general population, especially in individuals of the same gender, age, and race as

the deceased. Although it has been found in the United States that the imitation effect holds for entertainers (such as actors and television stars) and political celebrities, this effect has not been reported for other categories of celebrities, including artists and the economic elite. It is possible that the number of people who can strongly identify with elite artists and imitate their self-destructive behavior is too small to have a significant impact on rates of suicide. The exception may be stars of popular music and writers who have gained a wide fame and recognition, such as Ernest Hemingway. It is of interest to note that the suicide of Kurt Cobain, the lead singer-guitarist and lyricist of the grunge group Nirvana in April 1994 did not lead to an epidemic of suicides among his fans despite his worldwide fame and the excessive media coverage of his death. A few cases of imitative suicide were found in the United States and Australia immediately after Cobain's death and an increase in the number of calls to the local suicide crisis center was recorded in Seattle. However, outreach, education, and support by the local community, an attempt at responsible media reporting of the suicide, as well as Courtney Love's (Kurt Cobain's wife) message to the grieving fans which made the death real and disturbing might have de-romanticized the death and decreased the risk of imitation and contagion.

Conclusions

The study of suicide and creativity, and the possible links between the two phenomena suffers from several limitations plaguing most biographical research, such as the use of soft journalistic and biographical resources, making retrospective psychiatric diagnoses based on nonclinical data, and the impossibility of a prospective study. Also, due to the prevalence of males in creative and artistic professions, mostly a result of historical and social circumstances, there is a paucity of knowledge about suicide in creative women. It can be concluded, however, that suicidal behavior appears to be more common in creative people, particularly writers. It has not been proved that creativity per se is responsible for an increased risk of suicide. The most likely explanation for the association of suicidal behavior with creativity is that creative people are more likely to have an affective disorder, typically manic-depressive disorder, and to abuse alcohol, characteristics which are associated with a higher risk for suicide. Particular occupational stress factors and personality traits may also mediate the link.

Synesthesia

J Glicksohn, Bar-Ilan University, Ramat Gan, Israel

© 2011 Elsevier Inc. All rights reserved.

Glossary

Concurrent The synesthetically induced sensory attribute (e.g., color).

Eidetic imagery The ability to retain a relatively accurate and detailed visual image 'out there' and not 'in the head.'

Hallucination Perception of an event (e.g., someone calling out your name, or an image suddenly appearing in a mirror) 'out there,' having no objective basis, which is accepted

by the percipient as being veridical. A dream is a hallucination.

Inducer The inducing event (e.g., tone) for a synesthetic experience.

Physiognomic perception The fusion, or dedifferentiation, of perception and affect (e.g., 'sad moon,' or 'angry sky').

Poetic synesthesia The depiction of a synesthetic experience (e.g., 'sweet silence,' or 'yellow cocktail music').

History and Recent Developments

Synesthesia, derived from the Greek *syn* ('together' or 'union') and *aesthesia* ('sensation' or 'perception') is a term that came into use in psychology in the late 1890s. Certain individuals had the most *peculiar* perceptual experience of *colored hearing*, namely on hearing a melody they simultaneously experienced a train of colors – particular notes triggering particular colors. Was this an indication of arrested development, or degeneration, one of the 'hot topics' in the Parisian and Viennese salons at the turn of the twentieth century? Was this an indication of a sublime, esthetic state of transcendence? Do these *synesthetes*, who seem to be quite imaginative and sensitive, actually exhibit *creativity*? Certainly, some of the contemporary music of the time entailed the matching of particular tones to particular colors. In fact, *synesthesia* came into use in literary criticism in the 1930s (i.e., in the guise of *literary* or *poetic* synesthesia) – just when experimental psychology was shifting away from this topic – and the two fields have subsequently generated their own literatures separately.

During the first quarter of the twentieth century, synesthesia was one of the mainstream topics of investigation for experimental psychology, one of whose major tools for research was systematic introspection. Various papers on the topic appeared in the flagship *American Journal of Psychology* of Edward Bradford Titchener's introspective school. For example, one report from 1923 was made by a synesthete, who documented in detail various forms of color hearing, and other forms of synesthesia, that he experienced. One question that he investigated in this single-subject design is that of the relationship between a mixture of *inducing* stimuli (e.g., tones) and their *concurrent* experience (e.g., colors): What distinguishes a *blend* from a *clash*? Introspection reveals that when the inducers *blend*, the concurrent color experience entails a mixture of the colors of the components of the blend, whereas when the inducers *clash*, the concurrent color experience entails the side-by-side appearance of the colors of the respective components. Although this article was not cited by proponents of Gestalt psychology, which was gaining ascendancy in experimental psychology at that time, there is certainly a focus on molar forms of cognition here, one suggesting a distinguishing characteristic of a *gestalt* (blend) from a mosaic

(clash) which was easily accessible to synesthetes for further investigation.

Other papers appearing in that *Journal*, while not specifically having synesthesia as their focus of inquiry, nevertheless had recourse to discussing synesthesia as an inherent aspect of the subjective experience under investigation. Thus, a paper appearing in 1927 discussing 'felt experiences' (e.g., to cold), presents introspective reports describing the experience as being 'bright and cold.' The feeling of heat, in contrast, was described as 'flat like pressure and bright like pain.' One view of these reports is that systematic introspection of the sort employed by Titchener and his followers essentially entailed introspective sensitization, wherein the observer becomes sensitive to his or her subjective experience and exteriorizes what is essentially the common synesthetic background to his or her cognition. This, in turn, suggests that synesthesia is not necessarily a peculiar, idiosyncratic phenomenon, accessible only to a select few, but rather reflects a common substratum of cognition – one that enables us to function in a world requiring the blending of vision and audition, and vision and taste, and so forth, that comprises our multimodal perceptual experience. This is essentially the distinction between what has been termed 'weak synesthesia,' whereby we all lie on a continuum of synesthetic experience, and 'strong synesthesia' which is *constitutional*, or *typographic*, and which is certainly more dramatic than the commonplace association that we all have between 'red' and 'danger,' and 'black' with 'scary.'

The history of the field is of course a history of its protagonists. Titchener (1867–1927), who had made a very forceful argument for the *sensory* basis of all cognition, was publishing reports in the *American Journal of Psychology* indicating that, as expected, such was the case. The introspectionists of this school were providing detailed reports of their subjective experience, wherein vivid imagery – and especially vivid synesthetic imagery – played a major role. It perhaps may come as no surprise to learn that Titchener himself was probably a synesthete.

Introspection, however, was not the only tool of experimental psychology during those years. There was, of course, also psychophysics, and it is notable that even when introspection was considered to be *passé* (at best) or *unreliable* (at worst) as experimental psychology took on a Behaviorist orientation for the next 30 years – with the untenable argument that the study

of mind (hence, the study of synesthesia and creativity) was not the proper goal of the science of psychology – a psychophysical study in the lab was considered to be acceptable. Synesthesia, especially weak synesthesia, which implicated some lawful relationship among the various modalities of perception, was thus amenable to continued research within psychophysics. Since the 1970s, it has been Lawrence E. Marks with his students and colleagues, who have presented a psychophysical approach to synesthesia. From these studies on colored hearing, for example, we have learned that the *higher* the frequency of the inducing tone, the *brighter* is the concurrent experience (this was also an established correspondence at the very beginning of experimental work on synesthesia). Marks has focused on weak synesthesia, including the study of poetic synesthesia.

George Domino's chapter for the first edition of the *Encyclopedia of Creativity* is one of the items appearing in the bibliography to the present article, and provides a useful resource for the literature until 1999. What has happened since then? Using the *ISI Web of Knowledge* resource, one may note that in the four years prior to the appearance of the first edition of this encyclopedia, interest in the field of synesthesia (or synesthesia) was somewhat marginal. In the past decade interest has notably increased (see **Figure 1**).

Research over the past decade has stressed that synesthesia can inform the rest of cognitive psychology and cognitive science. Among the issues researched in this connection are numerical cognition and automaticity. Consider, for example, the notion that for a particular synesthete the number four triggers the experience of *red*, while the number six triggers the experience of *green*. If the digit '4' is printed in the color *green*, while the digit '6' is printed in the color *red*, one can investigate a Stroop-like situation at the individual level, wherein the synesthete is asked to state the color of the ink (*green*, or *red*) in which the digit is printed, while ignoring the digit itself (4 or 6). While this should be an easy task for a nonsynesthete, the synesthete should experience Stroop-like

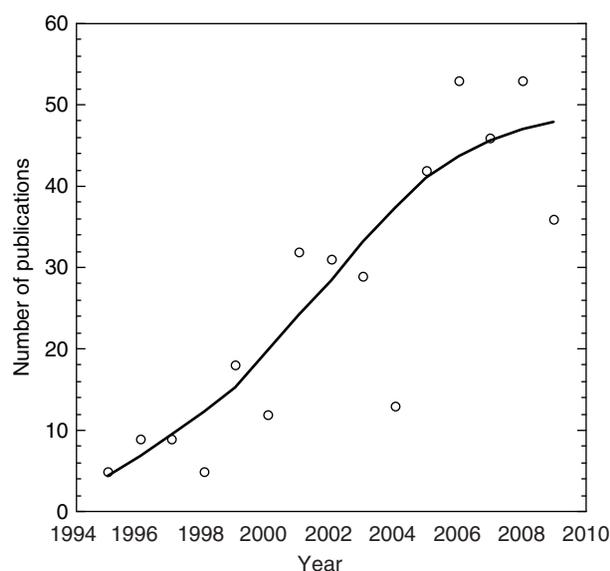

Figure 1 Increasing interest in the field of synesthesia over the past 15 years. Source of data: *ISI Web of Knowledge*.

interference. This research notwithstanding, what have we learned about the relationship between synesthesia and creativity? In Domino's chapter, he cites a single empirical study providing evidence of a relation between these domains. More recent research is not overabundant, and will be discussed further on. What seems to be happening in the literature is that there is a focus on synesthesia as being a productive inroad into studying various issues of topical interest, while at the same time helping to further establish the field as a viable one in itself. However, the synesthesia–creativity relationship does not seem to fall within the main focus of such research. One way out of this impasse is to look at synesthesia as it is related to other phenomena, and indeed to reconsider a *Gestalt* approach to both fields of inquiry.

Synesthesia and Related Phenomena

Synesthesia was one of the phenomena considered by theorists having a *Gestalt* orientation. This line of thought stretches from the early twentieth century to the present, and bridges between perceptual and literary (or, poetic) synesthesia. This section is devoted primarily to discussing such a heritage, which has important implications for the study of synesthesia and creativity. As is apt for such a Gestalt orientation, the reader is invited to test himself or herself on a series of tests for synesthesia that can be found at the following site: <http://www.synesthete.org>. As noted above, one might consider synesthesia and synesthetic experience as lying on a continuum, with one pole marked by the type of 'strong,' 'constitutional,' 'classic,' or 'typographic' synesthesia that has been discussed by Richard E. Cytowic. In fact, one might further consider that synesthesia is but one of a family of what have been termed *syncretic* phenomena by Heinz Werner (1890–1964) – that is, together with eidetic imagery and physiognomic perception – where by 'syncretic' one is referring to the fusion, or *dedifferentiation* of perceptual qualities in subjective experience. Synesthesia entails the dedifferentiation of the sensory modalities (as in colored hearing) – what others have referred to as a 'break-down of modularity.' Eidetic imagery entails the dedifferentiation of imagery and perception, allowing for a hallucinatory or pseudo-hallucinatory form of subjective experience (i.e., the experience of a visual image which is relatively accurate in detail, but within which there is room for subjective elaboration). Physiognomic perception entails the dedifferentiation of affect and perception (e.g., a young child's depiction of thunder as looking like her own angry face with brows drawn together).

Eidetic imagery and synesthesia have been noted in the same individuals, leading one to believe that *eidetikers* and synesthetes are one and the same. This has implications with respect both to a question regarding the prevalence of synesthesia (and eideticism) in the normal population, and to the defining characteristics of the synesthetic (and eidetic) experience. Prevalence estimates wax and wane with the times. Prevalence estimates of between 10 and 15% of the adult population most probably refer to the weak form of synesthesia. Current estimates of the strong form of synesthesia might be in the vicinity of 0.04–5%. Turning to the literature on eideticism, one finds that in the adult population the

prevalence of typographic eidetikers might be in the vicinity of 0.1–1%. And yet, recalling (1) that synesthetes might very well be typographic eidetikers, (2) that both synesthetes and eidetikers might score high on the personality trait of *absorption* (see below), (3) that both synesthetes and eidetikers might be fantasy-prone, which is a trait positively correlated with that of absorption (see below), and (4) that typographic eidetic imagery might be recovered using hypnosis in such fantasy-prone individuals, it seems at least a fair working hypothesis to assume that this overlap in experience is indicative of the fact that it is the same target population of unique individuals that is being tapped, in the two fields of research. In fact, when these phenomena are viewed in unison, one also finds support for the weak form of synesthesia. Just as with respect to synesthesia, there is also a weak form of eideticism, termed structural eidetic imagery, most probably apparent to some degree in all individuals. Again, this is similar to Werner's notion that synesthesia could be induced in everyone, given the right conditions (e.g., the use of drugs – note further the relationship between drugs, the induction of altered states of consciousness, and creativity).

The three forms of syncretic phenomena are related. An example used by the Gestalt psychologists to demonstrate the correspondence between shape and sound can be freely translated into the problem appearing in Figure 2. One of these figures is termed *staccata*, the other is termed *galooba*. Which is which? And is this an example of synesthesia (as some authors write) or of physiognomic perception (which is the 'correct' answer)? And how is all this related to creativity? Let us construct the bridge: according to Werner, metaphoric thinking develops out of physiognomic perception. Indeed, physiognomic perception is said to serve as a base from which a poetic metaphor could be subsequently generated (e.g., "The approach of a storm is the windblown hair of a frenzied woman"). Physiognomic qualities may help to foster an 'as if' mode of perception and thinking required for comprehending a metaphor. This is the experiential, perceptual-like base that a Gestalt-oriented approach to metaphoric thinking posits. However, this is exactly the same line of thinking underlying a Gestalt-oriented approach to creativity.

It is perhaps no surprise to realize, therefore, that all three forms of syncretic experience can be used in the pursuit of

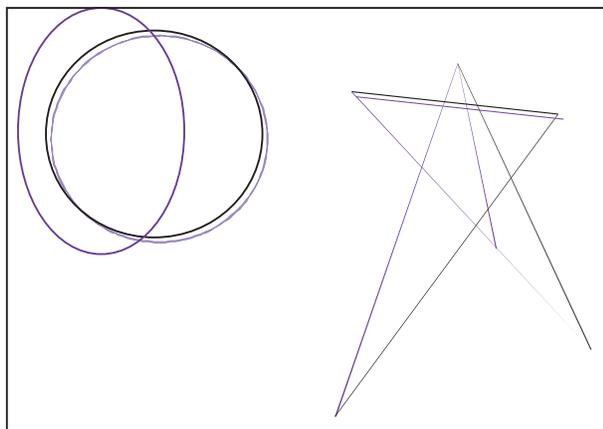

Figure 2 Which figure is *staccata*, and which is *galooba*?

creativity – artistic, literary, musical, scientific or whatever. Various studies have indicated that synesthetes are likely to be involved in artistic pursuits (e.g., painting, photography, music). It is also of no surprise that all three forms have been argued to reflect an arrested (or, derailed) development, a breakdown of normal modularity, or a dedifferentiation of modalities – all of which are variants on a common theme – and all of which could very well foster creative thought, if by this one means being able to restructure the perceptual field and hence find a novel solution to some problem. Indeed, various studies have indicated a relationship between physiognomic perception and creativity. Some authors have argued for an alternative route, namely that creative individuals have access to primary process modes of thought, and that both synesthesia and physiognomic perception are aspects of such primary process thought. In fact, both options have much in common, especially when viewed within the perspective of a *microgenetic* or *perceptogenetic* approach to cognition and consciousness. Microgenesis refers to an unfolding of a cognitive process (e.g., perception, thinking) that occurs in *developmental* sequence. Developmentally, one is progressing from a stage of global diffuseness to a state of "increasing differentiation, articulation, and hierarchic integration," in line with Werner's *orthogenetic* principle of development. Note that syncretic experience in general, and synesthesia in particular, is indicative of a developmentally early level of cognition, in this Wernerian sense. If creativity involves a 'regression in the service of the ego,' or a 'reordering of experience,' then the synesthesia-creativity relationship is one such route.

One notion that has appeared in the literature is of a developmental sequence, whereby physiognomic perception precedes synesthesia. Thus, an individual could be initially perceived in affective terms – say, 'he seems to be resisting,' which is subsequently described synesthetically – he's a 'cold' fish. While synesthesia has been reported in various altered states of consciousness (especially, but not necessarily, following the use of drugs), it is also the case that physiognomic perception is elicited. In Werner's terms, "the whole world becomes physiognomically alive."

Much effort has been exerted in establishing reliable criteria for synesthesia. First, in order for a synesthete to be considered 'genuine' he or she must be consistent over time in reported synesthetic experience (e.g., consistent matching of color to tone in colored hearing). Such consistency assessments are remarkably high (>90% after retesting a year later, in one study). More importantly for our present concerns are the following two criteria for strong synesthesia, which are identical to those advanced with respect to eidetikers. (1) The externalization of the image (eidetic image or synesthetic experience) – hence in *lexical* synesthesia, if the letter Q induces the concurrent color red, this color appears 'out there' (and not 'in the head'), and is located in the immediate vicinity of the printed letter, but is not necessarily confined in space by that letter.

(2) Use of the present tense in the subjective report – hence the synesthete reports seeing in real time colors, or hearing tones, or smelling fragrances, or feeling sensations, and does not recall some commonplace association to the inducing stimulus. And yet, even these criteria are at present being reassessed. Synesthetes are now being classified as being either 'projectors' (i.e., 'seeing colors in external space', as required by

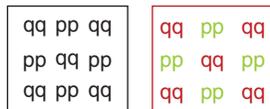

Figure 3 The similarity of form (*p* vs. *q*) in the display on the left can impede figure-ground differentiation – that is, when all elements appear in the same color. For synesthetes, if the letters have corresponding colors, as shown here, the embedded figure will pop out.

the criterion of the externalization of the image), or ‘associators’ (i.e., ‘experiencing colors in their mind’s eye’). Projectors are clearly typographic synesthetes of the sort discussed by Cytowic and others; associators are clearly exhibiting weak synesthesia – and whether this is genuine synesthesia, or the ‘experience’ of commonplace associations, is one issue that will have to be resolved by future research. If the two categories of synesthetes have any bearing on their degree of creativity is a further question.

Research over the past decade on synesthesia has utilized a number of perceptual phenomena – and especially those pertaining to perceptual grouping, as governed by the familiar Gestalt laws of perceptual organization – to provide convincing evidence that the phenomenon of synesthesia is genuine. Consider, for example, the display appearing in [Figure 3](#), which could easily be used to study lexical synesthesia. Various studies have employed such tasks to show either that lexical synesthesia can inhibit a response – for example, requiring a longer reaction time to respond to the color in which the letter is printed, in a Stroop-like situation – or can facilitate a response – for example, eliciting a faster reaction time to detect a form embedded in the display – which for synesthetes just ‘pops out’ due to their particular form of lexical synesthesia. While all of this is quite interesting *per se*, there is nevertheless a hidden assumption here – namely, that the projected color is coincident with the physical characteristics of the letters displayed. However, as various synesthetes have reported, the projected color can be blob-like, and can be composed of different colors. For example, the synesthete IW, as reported by Cytowic, describes a letter as being half dark red and half light red. Phenomenology should certainly not be discarded in the interest of methodology.

Six decades after the appearance of the paper investigating the *blend* of inducing stimuli, noted earlier, there appeared a paper looking at a similar question. In this case, a synesthete reported specific colors to specific letters (e.g., *U* = *yellow*). For her, the color of a word was unique to that word, and not to its constituent letters. In contrast, when presented with a nonsense word, she reported a compound color, derived from the combined evoked colors of its constituent letters. Evidently, the word was viewed neither as a blend nor as a clash, but as an *emergent gestalt*, having a unique concurrent experience.

Synesthesia and Absorption

Answer the following two questions (‘yes’ or ‘no’ in terms of your own subjective experience): (1) “If I stare at a picture and then look away from it, I can sometimes ‘see’ an image of the

picture almost as if I were still looking at it”; (2) “Textures – such as wool, sand, wood – sometimes remind me of colors or music.” The first pertains to eidetic imagery, while the second pertains to synesthesia. Both are items from a questionnaire assessing the trait of *absorption* – which is clearly related to both forms of syncretic experience. One would expect for synesthetes to score highly on the trait of absorption, if this is indeed a scale, and that is the case. As the authors (Rader and Tellegen in 1987) of one influential study write, “A capacity for absorption, that is, for engaging diverse representational resources, including one’s imagination and feelings, may be integral, possibly as a necessary rather than a sufficient condition, to the ability to experience synesthetically.” They further consider the notion that such individuals scoring high on absorption may be adept at reinstating the conditions (introspective sensitization?) under which synesthetic functioning occurs, and that this should be related to creativity. So, what do we know about synesthesia, absorption, and creativity? First, we should note the family resemblance underlying the personality traits of absorption, *openness to experience*, and *fantasy proneness* – such that their respective relations with creativity and synesthesia should all be considered. Forty years ago, Frank Barron noted that creative individuals possessed more ‘perceptual openness’ – this at a time when these particular personality traits were being formulated. Thirty years ago, it was found that individuals scoring high on fantasy proneness also scored high on absorption, imagination, and creativity. Such individuals, it should be stressed, scored within the upper 2–4% on a measure of imaginative involvement (hence were probably eidetikers and synesthetes). Further support for the relationship to synesthesia was reported in studies showing that individuals scoring high on absorption exhibited both synesthesia and eidetic imagery.

A number of studies over the past decade have documented the relationship between creativity and openness to thinking in both visual artists and student populations (assessing psychometric creativity). Visual artists have also been found to report the frequent incidence of altered states of consciousness (again, as predicted by absorption). Individuals actively engaged with the induction of altered states of consciousness, such as those related to contemplative (absorptive) meditation, report a higher incidence of synesthesia. One recent study reported that among long-term meditators, the prevalence rate of synesthesia was found to be 86%. A current notion is that the long-term practice of meditation “involves an attunement to a background field of consciousness” (that of synesthetic functioning?) that is necessary for creativity.

There is also a ‘dark side’ to absorption, just as there is a ‘dark side’ to creativity. With respect to absorption, this refers to an interaction with trait anxiety in the manifestation of intense negative emotion, which might well be detrimental to creativity. This is an issue worth further considering.

Unidirectionality, Bidirectionality, Synesthesia and the Brain

Progress into the study of synesthesia and creativity may be furthered once an unresolved problem regarding synesthesia is addressed, namely the suggestion or assumption that

synesthesia is inherently *unidirectional* (i.e., a particular letter evokes a particular color in lexical synesthesia, but that particular color might not be indicative of only that letter). However, there is the distinct possibility of *bidirectionality* here, and this has implications for synesthesia (or, perceptual synesthesia), literary synesthesia, synesthetic metaphor, and metaphor in general. Let us define our terms here. If synesthesia is viewed as entailing a fusion of modalities – hence of an *interaction* of separate cortical areas of the brain, say one area related to the processing of letters, another related to the processing of colors (see **Figure 4**) – then both cortical areas are implicated in (lexical) synesthesia, and unless one form of processing necessarily precedes the other, as unidirectionality implies, then both areas should be coactivated, hence resulting in bidirectionality. Some supporting evidence for this option has recently appeared in the literature using a Stroop-like situation, and the hunt is now on for further examples of such bidirectionality.

As Harry T. Hunt has recently argued, the notion of unidirectionality is rather puzzling for such an interactive process, but is instantly recognizable “as a variant of the directional asymmetry between vehicle and referent in all metaphoric usage.” Given the fact that at least some poetic metaphors are derived from synesthetic or physiognomic perception, unidirectionality thus becomes a common property of metaphoric thinking. Indeed, it is commonly accepted that in a metaphor, such as ‘the ocean is a harp,’ the ocean, which is the referent of the expression (or, ‘tenor,’ or ‘target,’ or ‘primary subject’) is being viewed in terms of the vehicle (or, ‘source’ or ‘secondary subject’) of the expression, namely the harp. It is also commonly accepted that our understanding of this directional expression is different from that of its inverse, ‘the harp is an ocean.’ However, as with synesthesia, various theorists of metaphor have considered a bidirectional view, which must be considered if indeed the metaphor is an emergent gestalt of its two subjects. Indeed, as Bipin Indurkha has noted with respect to this metaphor, there is a degree of symmetry here “in the sense that the perceptual resonance between the source and the target make them appear similar to each other. As the ocean looks like a harp, the harp also looks like an ocean.” Furthermore, adopting a Gestalt-oriented interactionist approach to metaphor, one notes as does Indurkha, that interactionism implies “that either component may serve as an interpretive base” and further that “the reciprocity of influence need not be completely equivalent, but some changes in both terms should

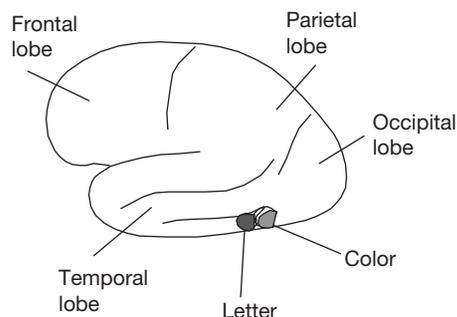

Figure 4 Cortical areas implicated in the processing of letters and the processing of colors.

be observed.” Further research on both synesthesia and metaphor will need to consider this unidirectional versus bidirectional issue.

It has been suggested that research in cognitive neuroscience should be guided by basic questions regarding cognition, and not by basic questions regarding the brain. It has also been argued that the present preoccupation with various brain-imaging technologies is more of a hindrance than an asset to resolving such basic issues. The study of synesthesia and creativity (and indeed of metaphor) has in the past decade attracted the attention of cognitive neuroscience. The question of unidirectionality versus bidirectionality in both synesthesia and metaphor seems to be one that could foster productive cognitive-neuroscientific research into synesthesia and creativity. Note that the Wernerian notion that synesthesia entails a dedifferentiation of modalities (or, a ‘breakdown in modularity’) is complemented by a contemporary view that synesthesia is indicative of a dedifferentiation in the brain.

Synesthesia and Creativity

What have we learned during the past decade about the synesthesia–creativity relationship? Admittedly, not much more than we knew at the time of the first edition of the *Encyclopedia of Creativity*. Nevertheless, the case has been made in the literature by two prominent researchers (Ramachandran and Hubbard), that number–color synesthesia may be caused by “hyperconnectivity between colour and number areas at different stages in processing” and that such “extensive cross-wiring between brain regions that represent abstract concepts . . . would explain the link between creativity, metaphor and synesthesia (and the higher incidence of synesthesia among artists and poets).” As noted above, such hyperconnectivity should implicate bidirectionality and not unidirectionality in synesthesia, and needs more research attention. Nevertheless, hyperconnectivity would be a strong candidate for creativity, and could certainly serve as a neural correlate for the synesthetic background to which the creative individual may be introspectively attuned to, as alluded to before. The individual who scores high on absorption could very well be able to exploit this background as part and parcel of his or her creativity.

A recent study has indicated, however, that synesthetes might be more engaged in art than in creative thought, though the one form of activity might not necessarily rule out the other. Indeed, one should distinguish between the various forms of creativity and its assessment. Musical creativity might well be related to colored-hearing synesthesia, and not necessarily to psychometric creativity as assessed using a measure of verbal divergent thinking. One should further consider the difference in both form of creativity (convergent, as in innovative though focused problem solving, or divergent, as in open-ended problem solving) and corresponding cortical areas (dorsolateral prefrontal cortex, and temporo-occipitoparietal cortex, respectively). It would surely be of interest to see a study on synesthesia – say one employing synesthetes exhibiting colored hearing – wherein the colors and tones themselves are to be used in problem solving. The reader is encouraged to follow up this suggestion.

Glossary

Formative causation A hypothesis proposed by biologist Rupert Sheldrake: all biological and chemical systems at all levels of complexity are organized by morphic fields. Under standard conditions anywhere in the world, permutations in one morphic field will occur more readily over time in similar organisms through inheritance of habits.

Implicate order A theory by physicist David Bohm. The universe is organized from within as well as from without. The implicate order underlies and enfolds all matter.

Morphic resonance According to Rupert Sheldrake in 1994, "Formative causation is the kind of causation responsible for form, structure, and pattern, and the causal influence on this is the morphogenetic field, morphic field, from the Greek word *morphi* meaning form. Each kind of thing has a field which gives its form, pattern, field or structure. This field is like the plan, the shaping influence has the kind of form it does because of its memory by the

morphogenetic fields. An influence of similar things on subsequent similar things. Fields have a kind of inherent memory within them that is nonmaterial but physical. The gravitational field is physical, it has physical effects, part of nature, but it's not material in the sense it's made of matter" (p. 18).

Synchronicity Synchronicity is the simultaneous or near simultaneous happening of coincidental events which have no cause. The odd events, because of their occurrence so close in time, are instilled with meaning by those who recognize them.

Trickster A mythological character found in many cultures, who transforms aspects of the world and who plays pranks. Often in the form of the raven, the coyote, the spider, the mink, the blue jay, or the rabbit, in North American Indian cultures; of the monkey in Asian cultures; of Hermes and Prometheus in Greek mythology; of Loki in Norse mythology.

Introduction

Synchronicity has several domain-based relationships with the concept of creativity – through psychology, through biology, through chaos theory mathematics, and through the new physics. In psychology, synchronicity is defined as the occurrence of meaningful coincidences that seem to have no cause; that is, the coincidences are *acausal*. The underlying idea is that there is unity in diversity. In psychology, Carl Jung introduced the concept in his later works (1950s). In biology, Rupert Sheldrake's work on morphic resonance has principles similar to those of synchronicity. In systems theory, Ernst Lazlo's work on chaos theory has also affirmed the idea of synchronicity. In modern physics, Bohm's work on the holographic cosmos is most consonant with the concept of synchronicity. Creativity and synchronicity have to do with these four concepts.

Synchronicity and Psychology

Jung waited until late in his career to focus on synchronicity because of its controversial and nonempirical implications – that effect does not logically follow cause, even though he first used the term publically in 1930. Among his experiments, he tallied the similarity in married couples' astrological profiles. Mathematicians and scientists were shocked and dismayed that he would give such credence to astrology. His editors urged him not to publish his 1955 monograph on synchronicity in his *Collected Works*, but after a long delay, in which Jung questioned the very premises of empiricism, the work was

published, with few changes. In it, he cited Kammerer's work on multiples, Schopenhauer's work on the first cause, the work of Davies, Richey, and Hammerian on probability calculus, Wilhelm Von Scholz on how lost or stolen objects come back to their owners, Herbert Silberer's on how chance functions from a psychological angle, and J. B. Rhine's experiments with extrasensory perception as evidence of a force called synchronicity. He focused on Rhine's work, saying the experiments show that events may be meaningfully correlated but not causally correlated, and therefore meaningful coincidences have archetypal roots. Jung also worked closely with physicist Wolfgang Pauli, who was interested in synchronicity as an explanation for the behavior of atoms in quantum mechanics. Jung defined *synchronicity* in several passages:

- Simultaneous occurrence of two meaningful but not causally connected events.
- A coincidence in time of two or more causally unrelated events which have the same or a similar meaning.
- The simultaneous occurrence of a certain psychic state with one or more external events which appear as meaningful parallels to the momentary subjective state and in certain cases, vice-versa.
- Synchronistic events rest on the simultaneous occurrence of two different psychic states. One is the normal, probable state (the one that is causally explainable) and the other, the critical experience, is the one that cannot be derived causally from the first.

Synchronicity does not only show its effects in the present, it shows its effects in the past and the future. Synchronicity has

to do with the physical principles of time, space, and causality. Jung asserted that people who are able to perceive in the present, events that occur in the future, with what is called 'extrasensory perception' or 'precognition' proves that such events are synchronistic, having to do with a relationship across time, and not synchronous, taking place at the same time. They fall into the same category whether they are separated by space or separated by time. Jung gave three examples that he said showed that space and time are, in their essence, one and the same:

1. A woman in therapy dreamed of receiving a scarab pin. While she was describing the dream, Jung heard a buzzing rap at the window. There, simultaneous with the woman's story, was a golden beetle, similar to the Egyptian scarab beetle, which is a symbol of rebirth in Egyptian mythology. This was an example of synchronicity in which a psychic state simultaneously occurs with an external event that coincides with the content of the state.
2. A woman saw birds gathered outside the rooms in which her grandmother and mother died. Jung was treating her husband for a neurosis. The man seemed to exhibit signs of heart trouble. Jung sent him to see a doctor. The man was given a clean bill of health. On the way back home after his appointment with the doctor, with the papers in his pocket, the man collapsed of a heart attack. The woman reported that soon after her husband had gone to the doctor, she saw a flock of birds land on their house. She remembered what had happened at the deaths of her mother and grandmother, and was very fearful. Her fears were justified. Jung said this was an example of synchronicity where the woman's unconscious had already perceived the danger to her husband. The first two incidents of birds landing were coincidences that set up a correspondence in her that could only be proved when the man's dead body was brought home.
3. A man in Europe dreamed the death of a friend in America. The next morning he received a telegram that the friend had died an hour before the dream occurred. Jung said that such experiences commonly happen almost simultaneously with the event, just before, or just after it happens. The person had unconscious knowledge of the event.

The two necessities for synchronicity to take place are (1) the presence of emotion and (2) an unconscious image which comes to consciousness either directly or indirectly. The melding of space and time are crucial and how the energy is transmitted is not known, and perhaps unknowable. Jung said that there is no explanation for the transmission of energy in these cases. The experience of synchronicity is indelibly interwoven with a sudden emotional recognition that something is momentous, important, consequential, and thus carries great weight. The surprise interrupts what we take for granted as cause and effect.

Jung conjectured about three different ways of understanding synchronicity, focusing on how intuition has worked in a way that is statistically significant.

1. One could look at the ESP experiments, which provided statistical empirical evidence that such events exist. In the ESP experiments, the subjects did better when the tasks

were fresh and their emotion and interest was focused. As the tasks repeated, boredom set in, and they did not do as well. This shows that emotion is indeed necessary for synchronicity to occur.

2. If we look at the Chinese way of holistically seeing the world, rather than the western way of seeing the world by analyzing small parts and generalizing to the whole, we can see that the concept of synchronicity is more explainable. The ancient Chinese practice *I Ching*, based on the concept of the Tao, where one throws stalks of yarrow (or, in the west, three coins) in order to grasp the meaning of an event or to predict the future, is based on intuitive principles. (Jung did much work with the *I Ching* and first used the word synchronicity at the funeral of his friend Richard Wilhelm, who had translated the *I Ching*.) When an intuitive person who understands the 64 mutations of Yin and Yang interprets the tosses, the interpretation taps into the inner knowledge of the person, which is the same as the person's psychological state at that time. This state is synchronous with the chance falling of the coins or sticks. Thus the results are meaningful, but there is no cause or explanation for the meaning.
3. Jung settled on another intuitive technique based on ancient science, and that was astrology. He conducted an experiment with 80 married couples and found that their signs were compatible to a degree that was statistically significant. A mathematician colleague of Jung's looked at the data and found that 25% of the couples had signs that were compatible. Of course, the other 75% did not. Jung said such astrological coincidence has little chance of being proved by mathematical law, and that astrologers would argue that probability mathematics is not subtle enough to decipher the many permutations that influence the married couple's charts and signs.

Jung reviewed historical antecedents to the idea of synchronicity, cautioning that the rationalistic view of people in the West is not the only possible explanation for events, and in fact, the rationalistic view shows short-sightedness, prejudice, and bias. He cited the western practices of astrology, alchemy, and mantic practices such as tarot and *I Ching* as being open to synchronicity.

Jung referred to Schopenhauer's idea of the unity of primal cause, Leibniz's idea of preestablished harmony, and Kepler's idea of a geometrical principle that underlies the physical world. Jung said there must be some girding idea or principle which can explain these seemingly coincidental happenings. Noting that both primitive and medieval people did not doubt the existence of synchronicity as explanation for seemingly acausal events, Jung asserted that it is the role of psychology and parapsychology to take into account the fact that synchronicity might explain such events.

Jung pointed to dream analysis, and focused on his principle of the collective unconscious, which is an underlying species memory, common to *Homo sapiens*, that is expressed in archetypes, overarching mythic figures which appear similar in myths and fairytales in all societies. They are primordial images that exist in the unconscious and surface in dreams, images made in art forms such as poetry, painting, and music, and in fantasy, delusions, and delirium states of people alive today.

In 1961 Jung stated that the form of archetypes is comparable to the form of a crystal, which is preformed in the liquid from which it rises, even though it does not exist materially by itself.

Jung worked with physicist Wolfgang Pauli, who postulated that synchronicity is the fourth pole in a unity of time, space, and causality. Pauli pioneered with his explication of the exclusion principle, which stated that electrons cannot share the same path of orbit in an atom. This led Pauli to assert that quantum physics did not uphold the idea of universal principles and thus began the era of 'new physics.' Pauli and Jung proposed an addition to classical physics, that of synchronicity.

Arthur Koestler described synchronicity as even more enigmatic than extrasensory perceptual phenomena such as telepathy and precognition. Humans have been infatuated with such riddles since the beginning of mythology. These riddles contain the perhaps accidental and coincidental meeting of unrelated events which seem to have no cause, but which also appear to be very important and significant. Koestler applauded Jung for working in concert with the physicist Pauli as he developed his theory. While Jung used Pauli as a quasi tutor in theoretical physics, Koestler faulted Jung for not following up on Pauli's ideas, but rather descending into the obscure by attributing synchronicity to the collective unconscious and to archetypes. Koestler noted that synchronicity has reached cult status.

Synchronicity in Biology

Synchronicity is expressed by the principle of morphic resonance in formative causation described by Rupert Sheldrake. According to Sheldrake in 1994, "the hypothesis of formative causation suggests that self-organizing systems at all levels of complexity including molecules, crystals, cells, tissues, organisms, and societies of organisms are organized by 'morphic fields'." These fields include morphogenetic fields which have to do with the how organisms, molecules, and even crystals inherently remember what previous bodies have done.

The case of the blue tits is an example. Over time, ornithologists noticed that small blue tit birds learned to pierce the tops of milk bottles left on the doorstep in the morning in Great Britain. The phenomenon was first reported in 1921. By 1947 the behavior had been noticed throughout Europe. Blue tits do not usually travel far from their homes and live only two or three years. In the Netherlands, milk delivery had been all but stopped during the Second World War. When milk delivery resumed in 1947 and 1948, the blue tit behavior also resumed. Sheldrake used this as an example of how organisms remember habits established by previous generations.

Sheldrake said that space and distance do not matter to morphic resonance, for information and not energy is exchanged. That is, the universal principles of space and causality do not apply. The hypothesis of morphic resonance explained by formative causation explains the patterns and events in nature to be "understood as regulated by inherited habits and not by universal and eternal underlying principles."

Mechanistic science after Descartes took for granted that there were universal principles that were inviolable, and that the task of science was to discover these principles. Thus

memory was 'stored' in cells in the brain or body; Sheldrake said this was not true; memory is part of a collective memory of the species inherited from former members of the species. In 1994 Sheldrake said that this is a concept similar to Jung's concept of the collective unconscious:

The hypothesis of morphic resonance enables the collective unconscious to be seen not just as a human phenomenon but as an aspect of a far more general process by which habits are inherited through nature. (p. 117)

Sheldrake commented that these two hypotheses – of formative causation and of morphic resonance – may seem mysterious, but the mechanistic idea that there are laws of mathematics that transcend nature are more mysterious, as they also rely on a metaphysical explanation for what happens in nature.

Synchronicity in Chaos Theory

In 1987 Ernst Laszlo formulated a hypothesis about mathematical wave functions that assemble themselves into forms and nested patterns or psi-fields. Laszlo theorized that once patterns are made, they probably will occur again. This is an expression of creativity in the universe, or cosmos.

In 2003, a biologist, Richard J. Bird, challenged the dictum of evolutionary biology, that random selection is order arising from disorder. Mathematically speaking, randomness is order. Since the Enlightenment, biological science has ignored and diminished coincidence, chance, and chaos, and has thus disenfranchised those, like Jung, who argued for meaning in coincidence and chance. Bird stated that chaos implies an endless order. Evolutionary biology rests on the assumption that although events are fundamentally random, some are selected because they are better adapted than others to the surrounding world. Bird said that synchronicity can be explained if we view the world not as random-selective, but as iterative-sequential. In a world view that is iterative-sequential, coincidence would be expected. His theory would then encompass the presence of coincidence and chance as being part of a mathematical recursiveness, an order of infinity.

Synchronicity in the New Physics

In physics, the principle of correspondence was cited by Niels Bohr to illustrate the discontinuum between the particle and the wave. Bohr later changed the term to "argument of correspondence." The idea of correspondence is related to the concept of the natural philosophers of the Middle Ages, who talked of the "sympathy of all things," and to the Greek philosophers such as Plato who postulated an underlying ideal form.

David Bohm expressed the theory of the implicate order, which is the order that underlies what is external, or the explicate order. The implicate order is part of and contains the explicate order. Bohm saw the universe as a hologram, where each part is enfolded into each other part. The synchronicity in this theory is that locality disappears. Time, space, and causality are not evident in events that happen. What may seem to be creativity may instead be the expression of synchronicity.

Bohm also proposed a superimplicate order, which may contain a unifying principle. Intuition may be an expression of the superimplicate order functioning to perceive the implicate order and therefore the explicate order. The notion of the 'sixth sense' is similar to the notion of synchronicity.

Synchronicity in Cosmology

In 2006 Richard Tarnas noted that synchronicity throughout history has provided for those who listen, a "dawning intuition" with great emotional and personal import, especially spiritually. He said that such experiences carry with them "a certain numinosity, a dynamic spiritual charge with transformative consequences," that are so powerful that people usually keep the insights hidden in order to avoid ridicule. Tarnas used the example of Petrarch climbing Mount Ventoux in 1336, and randomly reading a passage from St Augustine which directed him to pay attention to natural phenomena, an event that has been credited with the symbolic beginning of the Renaissance. Tarnas cautioned against the shadow side of the idea of meaningful coincidence, the "exaggeration of the trivial to discover a self-inflated meaning," a narrowness of self-involvement that may signal selfishness and even psychoticism (p. 51).

Tarnas also took up the thread that Jung had begun, that of using astrological science to describe and understand events of recent history. The use of astrological science remains controversial to empirical scientists, and thus Tarnas' work is often relegated to the mystical and idiosyncratic by mainstream psychologists, but it has had an influence on analytical and depth psychologists. Thus, the literature on synchronicity is rife with opinions and explanations that have psychological import. The connection of synchronicity and psychology is very strong.

Synchronicity and Creativity

While synchronicity has been taken to heart in analytic psychology, and has been viewed with bemusement by physics and biology, what does synchronicity have to do with creativity? These and other theories evolving simultaneously from many branches of knowledge converge in the root definition of creativity, which means 'to make.' The root of the words 'create' and 'creativity' comes from the Latin *creatus* and *creare*. This means, 'to make or produce,' or literally, 'to grow.' Creativity is discovering the unity in diversity and making something new – an invention, a theory, a concrete object, a temporal illusion.

The Dictionary of Developmental and Educational Psychology published in 1986 defined creativity as "man's capacity to produce new ideas, insights, inventions or artistic objects, which are accepted of being of social, spiritual, aesthetic, scientific, or technological value." The *Random House Dictionary of the English Language, Unabridged Edition* published in 1988 noted that creativity was an ability, the ability to "transcend traditional ideas, rules, patterns, relationships or the like, and to create meaningful new ideas, forms, methods, interpretations, etc."

Thus synchronicity has two relationships with the concept of creativity. First is that seemingly acausal coincidences may jar a person or a group to have new ideas, to see the old in new ways, and force a person or a group to pay attention and perhaps change the old ways of behaving, acting, doing,

making. Second is that in the new cosmology where universal principles give way to unpredictable models (except perhaps in Jung's concept of the collective unconscious and in Bohm's of the superimplicate order) creativity is found in the constantly evolving and perhaps accidental forms and patterns that are being developed.

The former may be illustrated with the following: A woman wakes up. Last night she dreamt about a coyote coming out of a cave and licking her hand. At the dentist, she flips through a fashion magazine and sees there a new perfume called Coyote, in which the model is dressed in American Indian fashion, petting a coyote. She goes to work and receives a letter from a man called William Coyote who wants her to give a speech at his school. At lunch she tells her friend about these unforeseen coincidences. Her friend pulls from her purse a novel she is reading. It is called *Coyote Justice*. By the fourth coincidence, the woman has a strong feeling that there is something going on. She and her friend talk about the coyote as trickster in American Indian mythology. This begins a search that leads the woman to a life change as she begins to embrace the significance of the trickster figure in her life. These coincidences with no seeming cause are called 'synchronicity.'

An example of the latter is the following, as explained by Sheldrake. When random mutations occur, organisms must react in new ways. Organisms adapt to the genetic mutation by making a creative leap which synthesizes into a new pattern. These patterns are instituted by morphic fields, which get more powerful and instill habits into the organism if the organism is preserved through natural selection.

Thus the creativity that gives rise to new bodily forms and to new patterns of behavior is not explained by the random mutations alone. It involves a creative response upon the part of the organism itself and also depends on the ability of the organism to integrate this new pattern with the rest of its habits. (p. 141)

Thus synchronicity is basically creative whether at the level of the atom, the molecule, the cell, the organism, or the system. Enigmatic, inscrutable, mysterious, seemingly acausal, playful and funny, synchronicity makes us laugh, cry, pay attention, and shake our heads in amazement. In 1996, Combs and Holland stated it well:

Nothing is closer to the heart of the experience of synchronicity than the feeling that the world itself expresses creativity in synchronistic coincidences. Such coincidences often have more the feel of poetry than physics. (p. xxxiii)

Another way that synchronicity is related to creativity is that the concept of synchronicity itself has influenced many creators in their creative works. The surrealists, the expressionists, and the symbolists in art, music, and literature, created many works by paying attention to coincidences that had meaning in their lives. A song by the rock and roll musician Sting entitled "Every Breath You Take," from their 1983 album *Synchronicity* illustrates this concept: "With one breath, with one flow / You will know / A sleep trance, a dream dance / A shared romance / Synchronicity."

A new field, quantum aesthetics, has emerged, based on synchronistic principles, including Sheldrake's idea of morphic resonance. Those who advocate quantum aesthetics are poets,

novelists, visual artists, filmmakers, psychologists, and the like. A manifesto stated that the quantum aestheticians proposed that the dualism and rigidity in previous theories should give way to ambiguity, uncertainty, vagueness, and the interpenetration of opposites. They sought to throw out the dictates of previous generations, and to adopt the principles of quantum physics in their crossover work. Rather than differentiating reality into naturally exclusive levels, quantum artists believe that these levels are intertwined and thus inseparable. The use of collage, constellation, montage, and hologram provided media suitable to the synchronistic idea.

Intercultural synchronicity has also been discussed. How do people geographically separate come up with identical ideas and inventions? What can account for the simultaneous production of multiples in different lands and different cultures? Often cited is the theory of evolution, contiguously advocated for by Charles Darwin and Alfred Russel Wallace. Some argue that such creations are 'in the air,' in the *Zeitgeist*. Social psychologist Dean Keith Simonton has called this *sociocultural determinism*, and has argued that the creations are not identical, but result from the process that the well-trained scientists have undergone; he said that many such discoveries are not recognized by their creators – that is, the discoveries are peripheral and accidental and not central ideas to the scientists; that the discoveries are not truly simultaneous, but are separated by years. Other critics of the idea that synchronicity enhances the creative process call synchronicity an 'illusion,' a type of 'creative idealism,' which is too fanciful and which will lead to inventions and products that are not probable. In 1995, cognitive psychologists Thomas Ward, Ronald Pincke, and Steven Smith said:

This has often led to the development of fanciful theories about paranormal forces and the like, which tend to promote creative idealism; that are undergoing. (p. 86)

Thus, almost a century after the term was first mentioned by Jung, the concept of synchronicity is still controversial, with many proponents and many critics.

Glossary

Complexity theory The study of interconnected, interdependent, dynamic systems.

Cybernetics The art of steering, or the study of dynamic circular interactions and recursive patterns of organization.

System A group of interrelated and interacting elements that form a complex whole.

Transdisciplinarity An approach to inquiry that moves across disciplines to find pertinent knowledge to address a specific question, using the language of cybernetic, systems, and complexity theories.

Historical Overview

It is not possible to speak of a single systems approach. There are rather of a number of systems approaches, each loosely drawing on different aspects of a family composed mainly of, general system theory, cybernetics, information theory, chaos theory, and complexity theory. Systems approaches have been used in most of the social sciences, particularly sociology and management, but their use has extended into the arts and humanities.

Creativity researchers have used systems approaches drawing on very different sources and in very different ways. The main focus has been to highlight creativity as a phenomenon that occurs in the context of multiple systems, and therefore involves a network of interactions.

General System Theory

General system theory originated in the 1940s in the work of the biologist Ludwig von Bertalanffy who initially sought to find a new approach to the study of life or living systems. More broadly, Von Bertalanffy envisioned general system theory as a way to address the increasing complexity of the world's problems. General system theory emerged as an alternative to the dominant form of inquiry and way of thinking, reductionist analysis, which was criticized for being unable to address wholes, interdependence, and complexity. Reductionism is based on the assumption that scientific explanation of complex phenomena should be in terms of component, simpler phenomena, and that the whole is explained from the knowledge of its parts. General system theorists argued that reductionism abstracts a subject from its environment, with the isolation of a variable in a laboratory being the classic example, and that by studying an element of a larger whole in isolation reductionism is unable to account for systemic and emergent properties, or the way relationships and interactions form the organization of the life. General system theory was presented as a new way of thinking that allows for the study of interconnections among systems and accounts for the nature of 'open systems' which interact with their environments.

General system theory introduced key concepts such as *open and closed systems*, stressing the role and importance of context and environment, *equifinality*, or the way systems can reach the same goal through different paths, and *isomorphisms* or

structural, behavioral, and developmental features that are shared across systems.

General system theory positioned itself as transdisciplinary rather than interdisciplinary. Interdisciplinary refers to *interaction* between disciplines, whereas transdisciplinarity refers to going beyond or across disciplines. General system theory would be the common language across diverse disciplines. Central to this language was the concept of 'system,' defined as a group of interacting, interdependent elements that form a complex whole. It also pointed toward a new world view that emphasizes such key concepts as every system's embeddedness in other, larger systems, and the dynamic, ever-changing processes of self-organization, growth, and adaptation. It is not surprising therefore that systems concepts have been central to the rise of ecology as a field of inquiry, with such concepts as ecosystem. In creativity research the systems approach has also at times been referred to as an ecological approach, because of the emphasis on the larger ecosystem in which creativity emerges.

General system theory was generally interpreted to be equilibrium-oriented, and fundamentally static, particularly as interpreted in mid-twentieth century functionalist sociology. This focus on order and equilibrium was also one of the main sources for the initial critiques of general system theory's application in the social sciences, most notably in the functionalist sociology of Talcott Parsons. This was viewed as being fundamentally politically conservative and oriented toward maintaining the *status quo*, rather than open to creativity and change.

Cybernetics

In its early years, general system theory engaged in fruitful exchanges with information theory and cybernetics, most notably at the classic Macy conferences from 1946 to 1953. Concepts such as negative and positive feedback, entropy, and self-organization became part of the systems lexicon. Negative feedback is deviation-reducing feedback, which can be found in a thermostat. A decrease in temperature below a certain threshold kicks in the heating, so that a relatively stable temperature is maintained. Positive feedback occurs in so-called 'self-exciting' or 'runaway' systems when, for example, one person's rude behavior leads another person to respond even more rudely and the whole thing escalates until the arrival of the police acts as a negative feedback. Positive feedback can be

found both in vicious and virtuous cycles. People who do not exercise tend to feel more and more out of shape, and therefore feel less and less like exercising, which makes them even more out of shape, and therefore even less likely to move, and so on. Alcoholism and drug addiction also work through runaway positive feedback. But positive feedback can also kick-start a situation that has become stuck – the more somebody exercises, the better they feel, and so they keep exercising. With its focus on deviation amplification, positive feedback is also associated with creativity and innovation. If negative feedback maintains a system on course and in equilibrium, positive feedback's deviation amplification takes it toward disequilibrium and change.

Process

Cybernetics focused on process, on navigation (the Greek origin of the word, *kybernetis*, means steersman), and the connection and communication between events and concepts. A classic example is the relationship between order and disorder, or stability and change. Many paired concepts such as order and disorder were traditionally viewed as opposites and referred to as 'paradoxical.' From a cybernetic perspective they are viewed as forming part of one larger ongoing circular process (much like day and night), rather than static opposites. The connection between creativity, madness, and emotional instability dates back at least to Aristotle. It has become part of popular culture to believe creative people are a little (if not a lot) crazy. Research shows creative individuals score higher on measures of psychopathology and on measures of psychological health. They are therefore *both* healthier and more unstable, experiencing periods of instability but also having the ego-strength to rally from setbacks, and in the process experiencing a wider range of human possibilities. This is a more complex formulation than the simple suggestion that creatives are a little crazy, and one that, with a few exceptions (Frank Barron in 1995 and Edgar Morin in 2008) has not been fully explored in terms of its general implications for psychological health, the nurturing of creative potential, the importance of supportive environments for creativity, the role of 'positive disintegration,' and the role of disorder in the generation of novelty. Creative individuals, with their preference for apparent disorder, draw on disorder, in the form of the unconscious and the irrational as sources of novelty in their own work. Rather than fear disorder, they actively court it and believe an encounter with it can allow them to generate a higher, more inclusive ordering principle.

Cybernetic Epistemology

Cybernetics evolved into in what came to be known as 'second-order cybernetics,' which went beyond the useful but mechanistic concepts of negative and positive feedback. Second-order cybernetics moved from the study of *observed* systems to the study of *observing* systems. The fundamental role of the observer or inquirer in every inquiry became central, as cybernetics moved into the field of epistemology. Cybernetic epistemology was later to make a considerable impact in the field of family therapy, and in the sociology of Niklas Luhmann. Cybernetic epistemology holds that every statement is always made *by somebody*. The speaker/knower cannot be left out of

the equation, and there is no 'God's eye view from Nowhere.' One of the more radical interpretations of cybernetic epistemology holds that any statement tells us more about the speaker than about the event, object, or person she/he is describing. In the context of creativity, this leads to the view that creativity is always an attribution made by somebody. Certain more sociologically inquiries into creativity have in fact shifted the research toward those that make the judgment about what is, and what is not, considered creative in a field.

Chaos and Complexity Theories

In the 1980s chaos and complexity theories introduced important new dimensions to systems approaches. Whereas in general system theory the focus had been on systems in equilibrium, researchers now began to incorporate cybernetic concepts and study systems in states that were far from equilibrium. As a result they began emphasizing the role of self-organization, emergence, and unpredictability. These developments in science led to what has been called the 'challenge of complexity.' The irreducible complexity of phenomena ranging from atoms to star systems, from cognitive systems to human societies is increasingly clear. This complexity, which takes the form of interconnectedness, interdependence, and unpredictability is not amenable to reductionistic approaches. Eliminating the interconnectedness, interdependence, and unpredictability also eliminates many of the most important dynamic features of the system. Complexity is now being recognized as a basic fact of existence, whereas in traditional, reductionist approaches to research it was considered an exogenous, chaotic element that interfered with the 'purification' of the variable to be manipulated.

The term complexity is generally defined as the length of the minimal program required to compute a number. But this is an algorithmic definition, and another definition might be a measure of how hard it is to put something together starting from elementary parts. Complexity has also been described as a recognition of complex causality, where complexity entails a shift in our description of phenomena, which at minimum recognizes the cybernetic dimension of mutual, recursive, and circular causality. Central to our understanding of complexity is that it emerges out of the inclusion of relationships as a dynamic, constitutive process dimension of the phenomena we want to understand rather than viewing them as static elements in isolation from their environment.

Key Concepts

System

Central to the systems approach is the concept of *system*. Traditionally, science saw the world as made up of 'things,' reduced to the smallest significant variables, such as atoms or individuals. Both atom and individual mean *indivisible* or that which cannot be broken down further – the smallest significant variable. Scientific inquiry involved finding the smallest significant variable and isolating it from its environment to study it, preferably in a laboratory setting. With general system theory, the concept of system emerged as an alternative. A system is defined as a group of interrelated elements that make up a complex whole and exists in an environment. Open systems

interact with their environment, exchanging matter, energy, and information. Closed systems do not interact with their environment in any meaningful way. Rocks, for instance, are closed systems. They do not take in matter, energy, or information. Living systems need interactions and exchanges with their environment for their survival.

In a systems approach, the individual is understood as a system, interacting with a number of other systems, which may include family, workplace, neighborhood, and so on, depending on the nature of the research and the context. An understanding of the various systems an individual is embedded in is necessary in order to understand how a creative idea in somebody's head becomes a product. In order to understand creativity in organizations, for instance, we need to look at a series of interacting complex systems: the individual, the group, the department, the organization as a whole, the wider business environment (e.g., economic climate, trends, competition), and so on.

The traditional scientific reductionistic view saw the world made up of atoms, or things, that were not interconnected. The world was made up of what the systems approach would call closed systems. Closed systems do not require any exchange of matter/energy or information with their environment. Their context and interactions are not significant or epiphenomenal. A closed system view is inappropriate in the study of living systems, because no living system can be a closed system. Every living system exists in a network of relationships and interactions with its environment.

The concept of open systems offers us an entry point to understand the role of change and creativity. Open systems tend to be far less stable than closed systems, which are by definition systems in equilibrium, with no exchange with their environment. The openness of the system leads to constant interactions and exposure to difference and novelty, and therefore potential disequilibrium. The equilibrium of open systems is only relative because this structure is gradually, and sometimes quite rapidly, transformed by exchanges with the environment, leading to alternating periods of equilibrium and disequilibrium. The more complex the systems, the further from equilibrium they become, which means they are increasingly unstable, and therefore require great adaptability and resilience. This is especially true of human systems, which are modified by their experiences with their environments.

In a systems approach, everything that exists, exists in an environment. The traditional (or reductionistic) approach to inquiry focused on understanding the subject of inquiry by removing it from its environment. The ideal setting for research therefore was the laboratory. A systems approach stresses that every system is part of a larger series of systems. Every part exists in a larger whole, which in turn is part of a larger whole. In an organizational setting, the individual is a part of a group, which is part of an organization, which is part of a national economy, which in turn is part of the larger global system. Every system is part of a larger system, in a series of endlessly nested systems.

Closed systems are in equilibrium. They do not change, grow, or transform. The traditional view, dating back to Newton, held that the Universe was made up of closed systems. And from a perspective that views all systems as essentially closed, equilibrium is the norm. Change and creativity are

the exception. Historically, the dominant view of creativity reflected this position.

Once we start seeing the creative process as occurring in a network of open systems, our understanding of creativity and change are transformed. From a systems approach, it is not the case that open systems change. Systems *are* change. The problem is that our traditional way of knowing does not allow us to see that, because we have seen individuals and organizations as fundamentally static, and creativity change as an exception.

Open systems have an ongoing relationship to their environment, and have to react to, or initiate changes in, that environment. As they face environmental challenges, they experience periods of disequilibrium. Traditionally, it was believed that equilibrium was a vital goal for any living system, and disequilibrium was viewed as a temporary aberration to be avoided. In a systems approach, the role of disequilibrium is viewed as potentially constructive. An excessive focus on equilibrium stresses the importance of staying the same, and not changing. But research has shown that periods of disequilibrium are essential for change, creativity, and innovation for all systems, whether they are individual persons or organizations.

In 1995, Frank Barron wrote that we should think of "the person as a dynamical natural system, bounded yet open, that is in a continual state of disequilibrium (p. 11)." He went on to argue that the creative person, process and product were "Each, in a sense, is a 'field within a field' – a field that never closes, for we really are talking about open systems, delineated for purposes of abstraction as product, process, and person." (1995: 32).

Mihalyi Csikszentmihalyi (1997, 1999) has been a prominent proponent of a systems approach in creativity research. His 'DFI model of creativity' has three systems as its major components: the domain (D), the field (F), and the individual (I). Culture, he writes, is made up of a set of domains such as music, engineering, religion, and so on. What is considered creative in these domains is decided by the field, which is made up of the gatekeepers who decide what is and is not creative. Both domain and field are necessary to understand what we mean by creativity.

The visual arts are a 'domain,' and connected to this domain is a 'field,' made up of gallery owners, art critics, museum curators, important buyers and other key figures who decide what is and is not creative and valuable. They make the judgments that matter. These 'gatekeepers' are the individuals and groups who decide whether an idea is worth pursuing or not. They play a key role in the life or death of an idea, and learning how to influence these gatekeepers is often a necessity in organizational life. Having an idea is not enough – the idea also has to be "sold" and accepted, and this entails both social and influence processes. This view has led some researchers to argue that the 4Ps of creativity research – person, product, process, and press (the environment) need to be augmented by persuasion, the process whereby an idea is convincingly presented to the field. The 5P view extends the concept of creative process to include not just the emergence of an idea, but the larger process whereby that idea makes an impact in the field in order to be accepted as a creative contribution.

Another related implication of the systems approach is that creativity training which focuses exclusively on the development of individual creativity provides only a partial solution to the task of fostering creativity in organizations. If an

organization wants to become more creative, it is not enough for individuals to have more creative ideas. If management does not support creativity, and the gatekeepers are very risk-averse, or believe that “we’ve always done it this way, and there’s no need to change,” then training individuals with workshops that foster creative thinking may actually be counterproductive and frustrating, because the ideas may never see the light of day organizational creativity and innovation are systemic processes.

Focusing on only one part of the system is not enough to foster organizational creativity. A systems approach is transdisciplinary. It does not reduce creativity to one discipline or dimension. Using the DFI model requires going beyond psychology and into such disciplines as the sociology of art, aesthetics, cultural studies, and more. Focusing on one dimension, such as the role of brain hemispheres in creative thought, or the group process of an R&D group, without taking into account the larger organizational systems they operate within, provides us a partial view with potentially limited applicability.

A systems approach does not necessarily shift the focus on the sociocultural dimensions of creativity. Gruber’s evolving systems approach focuses on three interacting systems that in their interaction make up the creative act, namely knowledge, purpose, and affect which is essentially a cognitive approach. Amabile’s three interacting systems of intrinsic (or task) motivation, creative thinking, and expertise, form a componential model that can also be viewed as a system mode.

Beyond Either/Or: The Cybernetic Paradoxes of Creativity

A systems approach stresses the limitations of an either/or, binary logic, and emphasizes a cybernetic, recursive, process way of thinking. A reductive approach isolates and separates, whereas a systems approach distinguishes and unites. When we *separate* A and B, we state that there is no connection between them – they are literally separated. When we *distinguish* between A and B, when we make a distinction as opposed to a disjunction, we say there is a difference between A and B, but they are not necessarily separate or opposed. Between A and B there may be a spectrum of possibilities, in the same way that to say night and day are separate or opposites does not take into account the entire 24 hours, and ignores, for instance, dusk and dawn. When researchers who are methodological individualists argue that a person’s environment is epiphenomenal to our understanding of his or her creativity, they are essentially arguing it is not relevant to the inquiry and will not help us understand that person’s creativity. There is a strict separation between ‘inside’ and ‘outside,’ and inside is where the action is. An inquiry informed by systems approach would argue that while it is possible to emphasize the cognitive process, eliminating the importance of the context completely provides a partial and arguably mutilated view of the phenomenon. The individual is always interacting with his or her environment, and those interactions are significant and have an impact on the person’s ‘internal’ process.

One fascinating characteristic of much of the creativity research is on the role of paradox. This is found in the creative process in so-called Janusian thinking which involves holding seemingly opposed or self-contradictory ideas, or in the need for both convergence and divergence, in the characteristics of

creative groups, and most notably in the ‘paradoxical personality’ of creative person. Summarizing the extensive research on the characteristics of the creative person, Csikszentmihalyi stated in 1996 that:

1. Creative people have a great deal of physical energy, but they are also often quiet and at rest.
2. Creative people tend to be smart yet naïve at the same time.
3. Creative people combine playfulness and discipline, or responsibility and irresponsibility.
4. Creative people alternative between imagination and fantasy, and a rooted sense of reality.
5. Creative people tend to be both extroverted and introverted.
6. Creative people are humble and proud at the same time.
7. Creative people, to an extent, escape rigid gender role stereotyping.
8. Creative people are both rebellious and conservative.
9. Most creative people are very passionate about their work, yet they can be extremely objective about it as well.
10. Creative people’s openness and sensitivity often expose them to suffering and pain, yet also to a great deal of enjoyment.

Central here is the fact that these characteristics are not commonly found together in individuals. We usually say a person is *either* conservative *or* rebellious, passionate *or* objective, humble *or* proud, not both. When these characteristics are found together in one person, the term paradoxical is used to describe them. The term paradox means ‘contrary to received opinion’ or self-contradictory. In other words, this is not what we are used to, it goes against our expectations, and it is essentially puzzling to us because unusual and hard to understand.

The paradoxical nature of the creative personality and the creative process have been well established, and confirm that creativity involves a cybernetic process that goes beyond simple dualities (Mark Runco in 2007). Barron argued that, “The paradoxical must be accepted as part of human design. Without stability, we can have no flexibility; without discipline, no freedom; without knowledge, no creation; without subjectivity, no objectivity” (1995: 35).

Paradox, in other words, is an aspect of humanness, that is highlighted in creativity. Instead of holding key systems dimensions such as equilibrium and disequilibrium, order and disorder, as opposites, with an either/or logic, a systems approach views them as having a cybernetic relationship of both/and. In the traditional view, which originated in modernity, equilibrium, and disequilibrium, order and disorder were viewed in a hierarchical opposition, with equilibrium and order privileged, and disequilibrium and disorder considered to be problematic. A systems approach shows they are interrelated like yin and yang, and provide a potentially generative interaction. Complexity theorists in particular have been showing that this cybernetic relationship between order and disorder is central to the more interesting natural and social phenomena (Morin, 2008). The now popular term ‘on the edge of chaos’ shows how far this relationship has been taken, a cybernetic process of navigating on a razor’s edge of chaos, and has remarkable parallels to the way which creative individuals explore a wider range of human experience and appear to have more dramatic highs and lows, greater mental

health yet higher scores on psychopathology, more destabilizing experiences and yet using them to reach higher and more integrated equilibria.

Creative individuals have a generalized preference for disorder, and see in disorder (the unconscious, the irrational, the unknown) the source of potential novelty. Creativity researchers have criticized the focus on equilibrium and frictionless, self-esteem adaptation, and argued that in the healthy and creative individual, order needs to be confronted and challenged by disorder to lead to growth and creativity.

A systems approach assumes that all open systems in an environment must adapt to environmental changes, and therefore undergo periods of disequilibrium in which a new level of adaptation is found. This suggests that living systems engage in an ongoing process of learning and change. They are not static, but in a constant process. Open systems do not just respond and change in response to their environment: they also initiate change. They change their environment. They do not only respond to unforeseen changes in their environment, but they also cause events that for others are unexpected and unpredictable.

The traditional approach to scientific inquiry and social science focused on *prediction* and *control*. This reflects an understanding of the world, and of the organization as a stable, equilibrium-oriented, predictable machine. Machines are designed to be predictable and controllable, and are reliable because they are not supposed to deviate from very clearly set parameters. With input A, they reliably deliver output B. Clearly such an approach is problematic when applied to creativity, where the whole point is the generation of surprise emergent properties. Tellingly, the subtitle of a major book on complexity theory, John Casti's *Complexification is Explaining a paradoxical world through the science of surprise*. This gives us a clear indication of the shift from a Newtonian view, and shows how these new sciences are aligned with creativity research in its many forms.

From Control to Self-Organization

The systems approach has introduced the important concepts of *emergence* and *self-organization*. The term emergence is related to the popular systems concept that "the whole is more than the sum of its parts." The whole is an organized network, and as such has characteristics that cannot be reduced to single individuals. It is also true that the whole can be less than the sum of its parts. Indeed, it is clear that historically in the United States, unlike in Europe and Japan, groups have been viewed as less than the sum of their parts. Whereas there is a sizable literature on creative individuals, it is not until recently that there has been an interest in creative groups, and to this day there is still a strong trend in creativity research that holds individuals working alone are fundamentally more creative than groups. The assumption is that groups lower creativity – and therefore that the whole is less than the sum of its parts. Regardless of whether the whole is less or more than the sum of its parts, *the whole is an emergent property of the interactions of the members of a group or, more generally, the interacting parts of a system*.

The importance of control is challenged by the phenomenon of self-organization and gives some insights into the

creative group process. When new teams are brought together to work on a task, they have a tendency to self-organize. There may be a desire to control or micro-manage them, but in the context of creativity and innovation, self-organization refers to a system's capacity to develop its own values, criteria, and ways of working. A tightly controlled and micro-managed team can work well for routine tasks, but in the case of creative, nonroutine tasks, self-organization means allowing the system's members to develop their own ways of doing things, their own ways of getting from A to B. In the same way, rigid programming of our lives without being open to the possibility of change and widely differing perspectives, without being open to what emerges in the relationship between self, our task, and our environment, can drastically limit the potential for creativity.

The concepts of emergence and self-organization both reflect a recognition and valuing of *spontaneity*. This is not to be confused with chaos. A comedy improvisator group has a clear task, to be entertaining and funny. The group's performance emerges as the group members interact and surprise each other. In those situations the group members have to self-organize, and know when to take risks, try new things, and at times react to challenges and opportunities without even the time to think. Spontaneity and improvisation require a generative framework for the group to operate in, and both individual and collective skills. Jazz has provided a particularly rich source of examples of self-organization, spontaneity, and emergence for social scientists.

Emergence and self-organization are characteristics of open systems that are adapting to their environment in new ways. These two concepts move the emphasis away from centralized, hierarchical leadership in groups and organizations to more distributed leadership and interactions. Emergence and self-organization are also characteristics of creative processes. In the context of human organizations, these concepts pose challenges to the traditional notions of prediction and control, and suggest that managing creativity at all systems levels requires a recognition of greater openness to outcomes, unpredictability, individual and collective responsibility, and trust in the creative process and in the systems involved in that process.

Science, Systems, and Creativity

The systems approach connects individual creativity to the larger cosmic context, according to Frank Barron:

The human person is a form in constant process of change. From birth to death, that process is a creative one. It partakes of the creative process in all Nature. It is evolutionary as the forms of Nature are. In the individual case we speak of development and growth, in the general case we speak of evolution, but both are aspects of creativity. Indeed, psychogenesis is best understood in the context of cosmogenesis. (1995: 30)

He goes on to state that:

The psychology of creativity specifically, by asking how and under what conditions the phenomenon of distinct novelty may appear in human psychical functioning, links itself to the general scientific enterprise of describing the evolution of forms in the natural world. (1995: 33)

The psychology of creativity is therefore part of a larger enterprise of situating human beings in the cosmos, and the systems approach has been instrumental in creating this connection. It has also been central to a shift in the sciences toward a view of the Universe itself as a creative process. In the traditional Newtonian scientific paradigm, order was king, privileged above disorder, chaos, and 'noise.' Our understanding of the relationship between order and disorder was in terms of a binary opposition, and indeed a hierarchical binary opposition. Disorder was viewed as a function of human ignorance, something that would, eventually, with better knowledge, be integrated in the larger master-plan.

Order came from the Creator's master-plan. A perfect order is unchanging. But Darwin's theory of evolution documented change: in fact, it was all about change, and how it occurred over time. We have to keep in mind that before Darwin the assumption was that the design of all of the planet's creatures was God's doing. The design did not change over time. The new, emerging worldview articulated by scientists and even several leading theologians today has a radically different perspective on the role of order, organization, and the nature of creation. Creation is not the result of God's design, but of the generative interactions between species and their environment in a form of creative self-organization.

A number of important works in theology have stressed the importance of creativity, in many cases drawing on the work of Alfred North Whitehead in whose 'process' vision of the world creativity played a central role. In 2004, Harvard theologian Gordon Kaufman in his provocatively titled *In the beginning . . . Creativity*, argues that the notion of a Creator simply does not hold up to modern science, whereas placing *creativity* at the center of creation seems much more congruent. In both the sciences and theology there is therefore a substantial movement, infused with a systems approach, not only to address creativity, but to make it central to both the scientific and the religious underpinnings of our world and indeed the universe. It is for this reason that we will explore the relationship between cosmology and scientific worldviews, and the way human beings in the West have conceptualized creativity in their lives.

The Cosmic Context

At the beginning of the twenty-first century there is an ongoing scientific revolution. Two of the central factors in that revolution are a systems approach and the role of creativity. A systems approach to the study of nature and the universe as a whole has led to a new understanding of the universe and nature not as a clockwork, a machine, or as decaying, running down, but as fundamentally creative. This means creativity is not a remarkable and relatively exceptional phenomenon, but rather at the very heart of existence. In order to understand this shift we need to understand the history of our cosmology, or our scientific study of the Universe and our understanding of what the Universe is.

Three Paradigms

The Newtonian paradigm emerged in the seventeenth century. It portrayed the universe as a giant clockwork. In the thermodynamic paradigm of the nineteenth century, the Universe was

winding down, moving toward degradation and decay. A new paradigm has emerged in the last 50 years. This paradigm is not of a static nor of a decaying universe, but of a creative universe. The stress is on interactions, innovation, and organization. There is not just a different understanding of the universe, but a different way of thinking about, and inquiring into the universe. The interconnected, dynamic, changing phenomena science is exploring require a different way of thinking, and cannot be addressed solely by analysis. There is a new perspective on the world, one that is fundamentally systemic.

The three scientific paradigms described above reflect different views of the world. In Newtonian mechanics there is a worldview based on necessity. The clockwork by necessity requires certain specific mechanisms to be in motion. With equilibrium thermodynamics we see a worldview based on chance. Decay leads to randomness and dispersion. The study of far-from-equilibrium systems leads to a worldview of creativity.

The Newtonian Paradigm

The Newtonian revolution represented the first real coherent triumph of what we now call science. With his *Principia*, published in 1687, Newton presented in the form of mathematical equations the three laws that govern the motion of material bodies. Newton's work was particularly important because it presented Universal Laws of Nature. These laws seemed to give a window into the functioning and nature of Nature itself. Particularly powerful in Newton's work was its focus on prediction, order, and determinism. With Newton the universe became a gigantic clockwork mechanism, and each part had to play its role without fail.

The laws and principles created the foundation for general theories and predictions that could be tested through experiments. These experiments conducted following the scientific method, consisted of breaking systems down to their simplest components, a method now referred to as *reductionism*. This reflected an assumption that the world was made of basic building blocks called atoms. The underlying assumption was that these atoms exist in isolation from their environment, and that knowledge of the behavior of the atoms could be used to predict the future of the system as a whole.

Two fundamental things make up the Newtonian world: matter and energy. Matter and energy exist in the emptiness of absolute space and time. Matter is composed of atoms and even subatomic particles such as electrons and protons. Knowing the location, mass, and velocity of all the particles in the universe, the assumption of the Newtonian worldview was that it would be possible to predict the future. With progressive improvement in scientific knowledge, in other words, it was believed that eventually it would be possible to predict every event. The Newtonian world was therefore *deterministic*. Every event *had* to happen *by necessity*. Once set in motion, the universe unfolds following precise laws. The assumption was that fundamentally, the Universe is governed by simplicity and simple rules. There is an unquestionable order to the universe, and anything we consider disorder or complexity was simply a function of our limited knowledge. Simplicity, predictability, and determinism were central to the Newtonian worldview.

The Newtonian world was also 'reversible.' This means that time exists so that we may assess the interval between events. But past and future have no significance. Nothing can be said to actually *happen* in such a universe. This is a particularly interesting feature that defies common sense, but made perfect sense in the Newtonian world. Interestingly, it reflects the same static view of the world before Newton, which was considered a perfect, preordained, God-given hierarchical order: nothing actually happens, because the Laws of Nature are the Laws of God, and these laws are perfect, therefore no change occurs, is necessary, or even possible.

The Newtonian worldview had very clear implications for the nature of thinking. The power of prediction and control that the scientific method provided was staggering. The technology driving the Industrial Revolution was the result of the application of the new scientific method. Who, in the middle of this explosion of human power, could argue against it? The social sciences and the management sciences wanted to import the scientific method, in order to enjoy the same legitimacy as real sciences, and the same successes. Being a real science was defined largely by the capacity for prediction and control. The scientific method led to technology and industry, which in turn were the engine of progress.

The notion of progress became central to modernity. The belief was that the scientific method offered a way to get at truth in a way that was empirical, testable, and gave the user power. It's important to understand that before the scientific method was applied, human beings simply did not think this way. Before the scientific method, what was considered the 'highest' or most evolved form of thinking on a social level was a mixture of Aristotle, the encyclopedic Greek philosopher who had written about everything from logic to theater to biology, and the writings of St Thomas, which informed theology, drawn from the bible. In this premodern view, Aristotle and the bible were seen as unquestionable sources of wisdom. The concept of experiment that would give empirical proof as to whether a particular hypothesis was, or was not the case, was unheard of.

It is ironic that the worldview associated with the emergence of science and technology, with the Industrial Revolution, and an incredible outpouring of creativity, could not itself account for creativity. Creativity was still considered a 'gift' of genius, a moment of 'inspiration,' but not something that could be understood without stepping completely out of the discourse of science. In fact, creativity was not really addressed at all in science. Despite its title, in *The Logic of Scientific Discovery* the influential philosopher of science Karl Popper's 500 page work essentially dismissed the possibility of understanding the process of conceiving or inventing a theory, arguing that there was no logic or rationality – essentially no rhyme or reason – to the creative process. In doing so, Popper suggested that studying scientific discovery was essentially a futile process, stressing instead the context of justification, or the defensibility of theories. This reflects the scientific position that creativity was essentially a process that could not be understood and should therefore not be addressed by serious scholars. This marginalized creativity and reflected a modern opposition between rational, logical inquiry, and allegedly completely irrational or arational creativity.

Romanticism, a parallel movement in European thought that articulated a strong critique of modernity and particularly

industrialization, came out the arts and humanities. It was much more open to exploring the plight of the creative individual, but did so in a way that was much more poetic and eventually contributed to the mythologization of creativity and the creative person and process. Some of the myths that emerged with Romanticism include 'genius without learning,' which became the idea that the genius did not need to work hard or study because naturally gifted, and the notion of the misunderstood 'lone genius,' working in isolation from the rest of the world (see Alfonso Montuori and Ronald E Purser in 1995).

The Decaying Machine

The second revolution in science was ushered in by the second law of thermodynamics. It addressed the issue of irreversibility. Irreversibility is a very basic feature of the world from our everyday point of view. You cannot become young again, unbreak an egg, 'take back' an unkind comment, or 'unlose' your lost keys (you can find them in the *future*, of course). Literally we cannot go back in time to undo or reverse an action. And yet the Newtonian world was 'reversible.' Time as such played no role in it. Everything essentially stayed the same, and the movie could be played forwards or backwards with no visible difference.

With the second law, Rudolf Clausius in 1850 brought us the familiar concept of *entropy*. In a nutshell, the second law of thermodynamics states that in a closed system, entropy never decreases, where entropy is defined as energy that is unavailable for work. Entropy is the disorder or randomness in a system. So as a machine worked, some energy became unavailable for work. What this brought us is a view of the universe as a decaying machine, a closed, mechanical system struggling against the forces of corrosion and decay. A machine, yes, but a machine that is running down, and inexorably moving toward the end. Time was introduced into the picture, and its role was essentially to tear away at the primal perfection.

As a machine worked over time, it would gradually lose energy. But along with this loss of energy there also seemed to be another process at work that was not accounted for in Newton's Perfect Clockwork paradigm or in the paradigm of the Decaying Machine. Decay was not the only direction time seemed to lead to. There was a parallel time that seemed to defy the Universe's winding down. It was a time not of machines, but of Life.

The Universe and Creativity

It was Charles Darwin who added a completely new wrinkle to our understanding of the world. Before the emergence of science, it was generally thought that the world had been created in 4004 BCE, and everything on the planet was the result of God's plan. This meant that every creature on the planet had been placed there by God, in the 'Great Chain of Being,' and nothing had really 'changed,' because that would mean a deviation from God's plan. Darwin, on the other hand, suggested that life on the Earth had started quite simply, and evolved into more complex forms.

Darwin's world was not Newton's world, or Clausius's world. Newton's world was static. Clausius's was running down. Darwin's seemed to be getting more and more complex, indeed, 'evolving.' Darwin's original image of the evolutionary process was very much a product of his times.

Darwin presented a third scientific perspective – neither perfect machine, nor decaying machine, but rather an explosion of life, reproducing itself and changing and adapting as it did so. And in this process, time played an active, creative role, because things changed as they reproduced, and as they came into contact with each other. The principle of natural selection suggested that interactions between organisms and their environment played a central role in evolution.

Self-Organization and the Role of Disorder

One of the most interesting shifts in recent scientific thinking, in particular because of the sciences of cybernetics, and then chaos and complexity, has been a deeper understanding of the mutually constitutive relationship between order and disorder, information and noise. This shift also reflects a transition from a fundamentally static view of the world to one that is process oriented. Rather than seeing order as fundamental and unchanging, we are now seeing an ongoing process of order–disorder interaction organization that is the hallmark of self-organization. In the creative universe, disorder not only destroys structures, systems, and organizations but it is also central to their development and regeneration. The interaction of order and disorder can be generative of new forms of organization, and any order is the result of an ongoing process, not of preestablished forms.

Self-organization has been defined variously as making meaning out of randomness, or the spontaneous emergence of a coordinated and collective behavior in a population of elements. One of the key aspects of self-organization is the creation of order out of chaos, the integration of elements perceived as disorder into a larger, more encompassing organization. We might think of paradigms in science as an analogy. What is inside the paradigm is considered order, what is outside is disorder. Anomalies on the edge of the paradigm, what the paradigm cannot account for, may initially seem like noise, disorderly phenomena that cannot be accounted for. Indeed, the history of chaos theory itself shows how turbulent phenomena such as water flowing from a faucet were rejected out of hand as subjects of study for the longest time because they seemed simply inexplicable. Yet it is the study of these anomalies that led to the development of the new science of dynamical systems, also known as chaos theory. In this sense, chaos theory as a field of study was itself a creative self-organizing process, the spontaneous emergence of a coordinated and collective behavior in a population of elements (researchers), making meaning out of (apparent) randomness.

The term self-organization refers to a spontaneous emergence of collaborative behavior among elements in a system. The order out of disorder that emerges in an open system's interaction with its environment is subject to fluctuation. When certain levels of fluctuation are created by increasing complexity, a critical or bifurcation point is reached. At that point the system can move in any one of several directions until a new and more complex order may be established after a period of turbulence. If a higher order of organization does not emerge, the system returns to a previous, lower level of organization.

Creativity theorists have drawn parallels between the systems processes and the creative process, applying self-organization to the emergence of new ideas, to the creative

person, and the process of personal integration, and to creative groups. From a systems approach, premature articulation and selection of a solution is a way of reducing the disequilibrium created by a problem. This disequilibrium can be experienced as anxiety, fear, impatience, frustration, or irritation. Tolerance for ambiguity involves staying with the disequilibrium until a generative solution can emerge. The systems view also suggests why creative people, being more open to experience, and having a preference for complexity, might willingly disturb their own equilibrium in order to be challenged and stimulate their own creativity. The emergence of a new idea arises out of a process of self-organization. This demonstrates the applicability of a systems approach at various levels of granularity.

Conclusion

The implications of a systems approach to creativity are powerful. Not only does such an approach shift the research agenda to a more relational, open systems view, but it also situates creativity in a larger context, namely the context of cosmic creativity, which includes cosmology and evolution as well as social change. The application of the systems and complexity sciences to creativity is very promising. Because of the interconnected, paradoxical nature of creativity, these approaches may be able to address some of the vexing problems confronting researchers, and shed light on hitherto ignored dimensions of creativity.

Glossary

Accommodation One kind of tactic, used when the individual him- or herself changes. New information might be obtained, expanding the individual's knowledge base, or the creator's perspective on the problem or topic might change.

Assimilation A second kind of tactic, used when the individual changes the problem or representation of the problem.

Metacognition Thinking about thinking; the recognition that we can control our own thinking.

Overjustification Occurs when the person changes his or her opinion such that some activity that was initially intrinsically motivated becomes extrinsically controlled.

Procedural knowledge 'Know-how,' information about how to get something done. It is distinct from declarative, conceptual, and factual information. Tactics are the actions prescribed by procedural knowledge.

Social loafing One explanation for the superiority of working alone over brainstorming. It occurs when people assume that someone else in the group will complete the task at hand.

Introduction

Tactics are useful only if an individual is mature and interested in being creative. Maturity is necessary because tactics are metacognitive; they require the recognition that we can control our own thinking, and this is not apparent until early in adolescence. An interest in being creative is necessary because tactics are intentional, and the individual would not expend the effort unless he or she is interested in the potential result. They are also metacognitive in the sense that they are not dependent on effortless cognitive processes. Very importantly, then, they are relatively distinct from the processes that underlie traditional intelligence and general ability. This provides some optimism; it means that everyone, at all levels of ability, can enhance their creativity if they find, develop, and practice the right tactics.

Procedural knowledge is necessary for tactical behavior. Procedural knowledge is 'know-how.' It is information about how to get something done. In this light it is distinct from declarative, conceptual, and factual information. Tactics are the actions prescribed by procedural knowledge. If that knowledge depends on traditional intelligence, the distinction between tactical behavior and general ability is blurred. This is why I suggested that tactics are *relatively* distinct from traditional intelligence and general ability.

Tactics are not entirely dependent on procedural knowledge. Certainly they are influenced by attitudes. In fact, attitudes may be the easiest way to enhance creative behavior. Attitudes are relatively easy to change. Attitudes are related

to tactics in the sense that individuals must believe they are capable of creative thinking. They must be interested in creative ideas; they must be willing to take risks and try something new.

Tactics are often used in the classroom and the organizational setting. Educators, parents, and managers and supervisors often attempt to facilitate the creativity of their charges. Research has confirmed that such efforts pay off. There is, however, some question over the actual creativity of the results. Individuals can become more original in controlled settings, but skeptics question such efforts. Perhaps the originality learned from a training program does not easily or often generalize to the natural environment. A related question concerns attitudes: What is actually learned from training? Are new tactics learned, and learned in a manner that will generalize to the natural environment, or does the training simply change the attitudes of the participants such that they are more willing to try new things? Further research must address this question, but in some ways the answer does not matter. If behavior becomes more original, it does not really matter if that is a reflection of just tactics, or if it reflects tactics *and* attitude working together.

Classifying Tactics

Tactics for creativity and originality have been classified in several different ways. These classification schemes are reviewed here; they will structure the list of tactics reviewed.

One useful distinction between the different kinds of tactics was presented by Sidney Parnes. He referred to *let-it-happen* tactics and *make-it-happen* tactics. Incubation is an example of the former. Incubation cannot be forced, but it can be made more likely by taking a break from one's work, and perhaps by taking a walk or finding some optimally distracting activity. Let-it-happen tactics also include (a) being open to change and serendipity and (b) trusting your intuition and hunches. In these cases, the individual is not directing the process but instead allows it to occur and simply appreciates the results. Individuals may go as far as to put themselves in a position where incubation, serendipity, and the like are more likely to happen. Very likely, all tactics allow information processing that is below the level of consciousness and assume that at least part of the benefit is beyond control. Again, let-it-happen tactics may involve letting natural (e.g., intuitive) processing take place. Make-it-happen tactics are more numerous in the creativity literature. Unlike let-it-happen tactics, make-it-happen tactics are usually more detailed step-by-step procedures. "Be a contrarian: Think of things no one else will," is an example of a make-it-happen tactic.

A second way to distinguish among tactics involves stages of the creative thinking process. Certain tactics may be used within one particular phase or stage of the creative process. There are different stage models of the process but most follow from the theory presented by Graham Wallas in 1926, with preparation, incubation, illumination, and verification stages. Let-it-happen tactics are well suited to incubation, for example, just as tactics to 'seek out reliable information' and 'change perspectives' are well suited to the preparation stage.

Each of the four stages can be divided into two subcategories. For preparation, illumination, and verification this division reflects a separation between the subjective and the objective, or between the individual and everything else – the problem, the relevant information, the possible or tentative solutions, the setting, and so on. This subdivision follows from cognitive theories which divide information processing into assimilation (whereby information is changed to fit into an individual's existing personal cognitive structures) and accommodation (whereby the personal structures are changed to take advantage of the new information). (This subdivision for incubation may not reflect subject and object, but this is understandable because incubation is largely personal and subjective.)

Assimilatory strategies are those with which the creator changes the problem or representation of the problem. He or she might turn the problem on its head, for example, or work backward from the desired objective or solution to the initial state. This tactic works especially well for scheduling and travel arrangements. Strategies using accommodation are those with which the creator him- or herself changes. New information might be obtained, for example, expanding the individual's knowledge base, or the creator's perspective on the problem or topic might change.

Changes of perspective represent what may be the most general kind of tactic. This is because such changes underlie a variety of more specific tactics. Turning a problem on its head, taking time away from the problem, travel, seeking out

criticism or input, and many other tactics rely on some sort of change in perspective.

Problem finding is a kind of preparation and can be easily modified to identify and define problems such that creative solutions are more likely. Many problem finding tactics involve information or other resources; just above I alluded to a 'seek out reliable information' tactic, which is a good example. 'Question assumptions' is another example of a tactic that applies well to problem finding.

The tactic 'question assumptions' can also be worded, 'do not make assumptions.' This rewording is only noteworthy because it highlights the last distinction that can be used to classify tactics. On the one hand there are tactics that suggest learning new behaviors. 'Seek out challenges' is an example of this kind of tactic. 'Do not make assumptions,' on the other hand, is an example of what can be called an avoidance tactic. This kind of tactic suggests what should be avoided, like assumptions, routines, and conformity.

James Adams' excellent volume, *Conceptual Blockbusting*, reviews many different kinds of avoidance tactics. What he suggests we avoid are conceptual blocks:

- Perceptual blocks occur when we define a problem too closely or too generally, or we ignore important information or a useful perspective. We need to avoid preconceptions and stereotypes.
- Cultural blocks occur when we fail to utilize fantasy, play, daydreaming, and humor because, in our culture, they are not associated with serious work. Taboos can create blocks.
- Environmental blocks occur when we are distracted by our immediate environment, including people with whom we live or work.
- Emotional blocks occur when we are afraid of taking risks or are not comfortable tolerating the ambiguity that may be necessary while we incubate or think further about a problem. We may also be uncomfortable postponing a decision or solution or with challenges.
- Intellectual and expressive blocks occur when we are inflexible or do not consider alternative media for representing a problem. We might also fail to obtain the most useful information. We might find a solution but fail to record it.

Each of these ideas can be translated into a recommendation. The last idea, for example, concerning the recording of our ideas, implies that we keep a pencil and paper next to the bed, in case we wake up with a good idea. We might take a small piece of paper and short pencil when we jog, and a small tape recorder when we drive.

David N. Perkins and Robert J. Weber described the role of tactics in their work on invention. They listed 'search strategies,' which are used to seek out information and options. They identified the following:

- Sheer chance.
- Cultivating chance (searcher deliberately exposes self to wide semi-random input).
- Systematized chance (survey of a number of possibilities within a defined set).
- Fair bet (prototypes a possibility with expectations that it will work with modifications).

- Good bet (prototypes from principle and experience).
- Safe bet (derives by formal methods something that almost certainly will work) (1992: 321–322).

Weber individually described the invention and refinement of inventions such as the Swiss army knife and the chair. He listed the following tactics:

- Finding ideas in nature.
- Assemble (the parts or components) for complexity.
- Fine tune what you have.
- Repeat or duplicate a feature.
- Add a feature.
- Delete a feature.
- Rearrange features.
- Join independent inventions.
- Transform and change the scale.

Although Weber's work was focused on invention, several of these strategies apply to all kinds of creative work. In fact, several parallel tactics are elsewhere recommended specifically for creative activities. Finding ideas in nature, for example, has been regularly suggested in the creativity literature. It is similar to other tactics as well, including 'borrow and adapt' ideas from others, and even 'find an analogy.'

The use of analogies may be particularly powerful:

Eli Whitney developed the cotton gin after seeing a cat trying to catch a chicken through a fence; Samuel Morse apparently put stations in the telegraph after thinking about stagecoaches changing their horses periodically; Pasteur used an analogy of grapes and human skin; the benzene ring may have been suggested by a dream of a snake biting its own tail; George Bissel used an analogy of a brine pump being used as an oil pump; James Watt was inspired to design the steam engine after observing a tea kettle; and Sir Marc Brunel borrowed from a worm for his work on underwater tunnels. Velcro and hundreds of other creative insights have resulted from the creative person finding apt analogies.

Many famous insights have resulted from a more direct borrowing strategy. Freud borrowed heavily from neurology and the medical model when describing the psyche; Piaget borrowed from biology in his theory of cognitive development; Darwin drew from geology in his theory of evolution. Musicians often borrow from various styles, the result being an original integration. Elvis Presley, for instance, apparently borrowed from gospel and country music.

Interpersonal Tactics

Tactics can be interpersonal. As noted earlier, certain tactics can be used by parents, teachers, or supervisors to facilitate the creative work of their charges. Parents and teachers in particular should encourage children and students, but should be careful to avoid overjustification. This occurs when a person changes his or her opinion such that some activity that was initially intrinsically motivated becomes extrinsically controlled. Incentives and rewards are common extrinsic controls,

and when individuals see them, they often assume that they are the reason for their actions – even if those same actions were intrinsically motivated moments earlier. Parents and teachers should shape confidence and ego strength. This is especially important because original ideas are often unconventional, and children become quite sensitive to peer pressure in preadolescence. During that period they may shy away from their own original insights. If they have ego strength, they may maintain their originality and avoid common slumps that occur in childhood.

Another interpersonal tactic is part of brainstorming programs. Participants in brainstorming groups are asked to generate as many ideas as possible and to postpone criticism. The participants are required to be careful of what they say to one another in an effort to maximize ideational output and minimize constraint. The tactic here is best summarized as 'postpone evaluation.'

The empirical evidence suggests that brainstorming may not be the most effective use of time. Working alone may be better. When people are in groups there is a tendency toward social loafing, and people may assume that someone else in the group will complete the task at hand.

Furthermore, it may be very difficult to postpone criticism, as required for brainstorming. In fact, it may not be a good idea to postpone certain kinds of evaluation. More likely a balance of divergent thinking and convergent thinking will benefit the process. With this in mind James March recommended a balance of play and reason. He suggested several tactics for finding a balance, including treating (a) goals as hypotheses, (b) intuition as real, (c) hypocrisy as a transition, (d) memory as an enemy, and (e) experience as a theory. The last of these – experience as a theory – is another way of suggesting that we question assumptions.

March suggested that the five tactics be used alternatively, with a temporary suspension of 'reasoned intelligence.' In his words, play and reason are functional complements. . . . They are alternative styles and alternative orientations to the same situation. . . . Our design problem is either to specify the best mix of styles or, failing that, to assure that most people and most organizations most of the time use an alternation of strategies rather than persevere in either one. (1987: 77)

One uncommon tactic was used by the Wright brothers when they worked on the first flier: they argued. Wilbur and Orville would take opposite sides of some technical problem, debate the issue, then switch sides and debate some more. It was, then, an intentional, tactical technique that the brothers used to help solve the problems of flight. Very likely the argument tactic led to a questioning of assumptions and a consideration of alternative perspectives.

One kind of tactic is interpersonal but focused on avoiding rather than collaborating with others. I am referring to the contrarian strategy. Here the creator does what others are not. This works some of the time because creativity requires originality, and a contrarian will be original because he or she is doing what others are not. Examples include Jean Piaget, Sigmund Freud, Duke Ellington, and Pablo Picasso. This is, however, a difficult tactic because it requires discretion and careful moderation. If someone relies on contrarian tactics

they could reinvent the wheel. Sometimes there is a good reason others are not doing something. Originality is not sufficient for creativity, so contrarianism is not in and of itself adequate. It can be taken too far.

Conclusions

Tactics can be defined by (a) distinguishing them from strategies, which are general plans rather than specific techniques; (b) distinguishing procedural information from conceptual and factual information; and (c) distinguishing cognition from metacognition.

Tactics take various forms and can be of the let-it-happen or the more structured and effortful make-it-happen variety, although here there is some blur and the distinction is imperfect. Make-it-happen strategies may involve some relaxation and preconscious processing, in which case there is a let-it-happen component to them.

Tactics can be personal or interpersonal; they can focus on the problem, as a kind of assimilation (e.g., 'turn it on its head'), or on the person who is dealing with the problem, as a kind of accommodation (e.g., 'change your perspective').

Tactics involving shifting one's perspective seem to be the most general. Some perceptual shift underlies many other tactics. The contrarian tactics, on the other hand, may require the most tact. This tactic did not always work effectively and might be best when used in moderation. Otherwise the result might be extreme but inappropriate originality, which is not synonymous with creativity. Very likely all tactics are best used with moderation and discretion.

Described as a “world poet,” RABINDRANATH TAGORE is considered a puzzling ecumenical figure, a paradigm of human possibility, a mystery, and a complex challenge of creativity who exemplified total creativity, unique and rare. As “Rabindranath” he was an Indian writer, as “Tagore” he was an international figure. He is known for his poetry, particularly “Gitanjali” (Song Offerings), which made him suddenly famous and brought him the Nobel Prize for literature in 1913, the second writer in English to be thus awarded after Kipling. One of the greatest literary figures in history, Tagore was a master of several literary forms. He experimented with many forms of art and sought an outlet first in music, then in drama, opera, and ballet and toward the end of his life in painting. Tagore was a consummate histrionic artist, a playwright and producer of plays. He also inspired and directed the revival and full development of the art of dance in modern India. Tagore is remarkable for his versatility, extraordinary range, and complexity of creative perspective. As a high priest of internationalism and the author of the national anthems of two countries, his spirited protests against the inequities and cruelties of British and other forms of imperialism and repression have a permanent place in history.

Rabindranath Tagore.

Background

Rabindranath Tagore, the product of history and of the social environment, was fortunate that at the time of his birth currents of three movements had met in the life of the country. He was born in Calcutta on May 6, 1861, and was the

fourteenth child (of 15 children), eighth son of his parents. The youngest child, however, died in early infancy, making Tagore both the youngest child and the youngest son of the family. Neither of the parents established any personal intimacy with him and early in life he lost his mother. There had never been that clinging affection between the mother and the son that would leave a void behind. But the thirst for mother's affection, never quenched in childhood, was to survive in the son as a constant longing for feminine affection and care. However, his father, known for contemplative inwardness, had the most abiding influence over the son. The influence had obvious manifestations later.

Tagore grew in a lonely and somewhat isolated family where literature, music, and painting were prized. The family was notable for the extraordinary concatenation of a variety of talents in its members. The house where he spent his childhood as a lonely outcast, a shy and quiet child, was to him tranquil and secluded. The family provided the right environment for Tagore to discover two of the major motives of his creative life: joy and mystery. The sense of wonder and mystery that for him pervaded the world of nature and men—the yearning for that mysterious world, the instinctive delight in the smallest and most common place things experienced in childhood—became for him a lifelong spiritual treasure.

Though he attended several schools, Tagore was allergic to formal schooling, which distressed him. His education remained desultory and ultimately he became a dropout. The education that he received at home was quite thorough. More valuable than what he was taught, was what he breathed in, as it were, from the atmosphere of the house, where Vedic chants could be heard along with readings from Shakespeare and Marlowe; where Indian classical music, vocal and instrumental, was seriously practiced while European music was also studied, where the family had its own drama group and compositions and collections of costumes; where a lively intellectual and spiritual endeavor was pursued with easy grace. Therefore, it is no surprise that this solitary and sensitive truant proved a recalcitrant boy who became a rebellious youth without the modicum of respect for tradition that normal systematic schooling imposes on an average adult.

Tagore admitted “the torn and the incomplete” in his makeup. He had a spate of bereavements and private and public disappointments, which could not stigmatize his work. Creative in crisis, the magic of his creativity hides the fact that it came out of a matrix not unaware of the tragic and the terrible.

The Complexity of Tagorean Creativity

When Tagore began his career, he was, as he put it, ridiculously young; in fact, he was the youngest of that band who had made themselves articulate. He had neither the protective armor of mature age, nor enough English to command respect. So in his seclusion of contempt and qualified encouragement he had his freedom.

As he grew in years, he steadily cut his way through derision and occasional patronage to recognize that the proportion of praise to blame was very much like that of land to water on our earth. The Nobel Prize, which he was awarded in 1913, brought to him “an immense burden of loneliness.” This was not only the recognition of his literary achievements but was also evidence of the impact of his personality on western contemporaries. During the World War I and for more than a decade thereafter, Tagore was hailed by the West and the East alike as a seer and a sage. Receiving the Nobel Prize was a turning point of his life.

His career and creative enterprises were largely conditioned by many influences and traditions, indigenous and foreign. His reason, personal will, and psyche only determined the form and character of this conditioning. Besides being influenced by *Upanishads*, Tagore was influenced by Buddhism, classical Sanskrit and English literature, Sufism, the *Vaishnava* poets, the submerged cultures of the rural agricultural folk and the *Bauls*, the itinerant singers who observed no formalities and were untouchables wandering from village to village, singing and dancing and taking delight in the ever-changing play of life. Tagore’s subconscious identification with the *Baul* credo was almost perfect.

These influences, in addition to the Indian reality, moulded his worldview. Tagore’s life pattern was essentially melodic and his creative genius had many facets, permeated with the idea of national liberation, of the struggle for the spiritual and political liberation from the yoke of colonialism and feudal survivals. Tagore’s multiple creative dimensions, issued from the same source and together formed an organic whole. While not denying the usefulness of expressions like “Tagore the poet,” “the essayist,” or “the playwright,” we must recognize that they overlap and interpenetrate and refer fundamentally to one unvariable reality. However, studying Tagore in a holistic framework involves risks and challenges not only of one man’s astonishing career but of a vast and intricate network of intercultural relationships. To compress Tagore’s versatility into a relatively brief account is to risk leading the reader with diffuse impressions that do the subject less than full justice.

Tagore’s complexity and extraordinariness was not of one kind, nor did he satisfy the demand for continuous development. It was a devious and diverse development, which defeats the too systematic critic at every turn. It has been noted that a paraphrastic, chronological account would be tedious and little more than a catalog. Tagore’s growth was not linear. Tagore was many poets in one, and not easy to track or label. His development did not have straightforward continuity and in fact overflowed the logical pattern of growth— it was instead a stage-wise progression. In short, Tagore’s development was not unilinear.

The Creative Purpose

Tagore’s purpose in undertaking creative enterprises emerged out of his concern for celebration of spirit and the infinite. He wrote that the desire we have to keep our uniqueness intact is really the desire of the universe acting in us. It is our joy of the infinite in us that gives us our joy in ourselves. Therefore, we must express ourselves strenuously in our life and work in “outward excursions.” The joy, which is without form, must create, must translate itself into forms. He, therefore, was sovereignly aware of the fact that “from joy are born all created things etc.” Though multitudinously various, Tagore gave a touch of completeness, an enormous unity, like the unity of a lyric, to his life. His life, it has been noted, was in fact, Tagore’s greatest work. When his other works are forgotten, his life will remain unforgettable because it is a true and silent answer to the most inward question of humankind: “How am I to live?” It has been noted that everything Tagore did and wrote bore the mark of his obsession with the maturing of the body and soul, toward the extension and intention, or renewal, of his own personality as a human being. He always aimed higher and higher, “The song that I came to sing remains unsung to this day.” His long life was densely packed with growth, activity, and self-renewal. He believed that in his creativity, one realized the supreme person (*Jivan-Devata*) who has made the universe so personal to humankind.

The Tagorean Peaks

“Thou who are the spirit of manifestation, manifest thyself in me.” This Upanishadic prayer was one of Tagore’s favorite quotations. This prayer, in Tagore’s case, was answered through diverse, multiple, continuous, and simultaneous literary enterprises. Poetry and the poetic consciousness was, of course, the animating principle in his extraordinary variety. In 1893, Tagore wrote:

The moment I begin to write poetry, I enter into my true self: true for all time. I distinctly feel that there lies my true home. Poetry is the sole refuge of all deepest truths of my life.

In May 1892 he wrote that the joy of writing one poem far exceeds that of writing sheaves and sheaves of prose. “If I could only write one poem a day.” He almost did that. Tagore, even before he was 20 years old, had published approximately 11,000 lines of verse which, with real good sense, he never reprinted. Before Tagore was 18 years old, he had published nearly 7000 lines of verse, and a great quantity of prose. Closely related to poetry, another creative enterprise that distinguished Tagore’s uniqueness was his incomparable songs. It was natural that he was attracted by a form of music that stressed the union of verse and melody. In the diversity of their mode and theme, these formed a class apart. The creative delight he discovered in his early musical experiments stayed with him until the very end of his life. When he was nearly 16 years old, he took liberties with the classical tradition and composed more than 2000 songs. From early boyhood

onward his music had the quality of profundity not inferior to the quality of his poetry.

In Tagore's career as a composer of music, the last 20 years of his life—from 1921, when he started composing his life series of songs on the seasons, to a few weeks before his death—were the richest, both in quantity and quality. Indeed this was the period when Tagore built the edifice that has now come to be known as *Rabindra Sangeet* or the Tagore school of Indian music. This was also the period when Tagore effected a perfect integration of music and dance, one interpreting and contributing to the other and thus expanding the horizon of both, which opened up new possibilities and generated new enterprises. During the 1925 and 1931 phases, his songs came to have a wide thematic range, variety, innovation, and the creation of new beat-rhythms or *tala*. Tagore's prose was as much a poet's work as was his verse. In him the poet and the prose writer were inseparable and mutually complementary, which means that we cannot assess the one without considering the other. The dramatic form interested Tagore very early in his career as a writer. He wrote more than 40 works of drama.

Tagore wrote several novels but this work, it is felt as a whole, may not claim to have attained the stature of his best poetry. Yet the novels are no less trendsetters in the unconventionality of themes, complexity of characterization, and poetic, often symbolic, language. The poet, the singer, and the teacher constantly meddled with the novelist and lured him away from concentration on one plot or one set of characters.

Tagore wrote an infinite variety of stories: comedies, tragedies, fantasies, and parables. Some are short novels, others long short stories. Apart from fiction and drama, Tagore's prose falls into a number of formal dimensions: belles lettres, literary criticism, essays on subjects other than literature, travel writing, autobiography, and finally letters. These divisions, however, are far from being rigid, for Tagore had a way of transcending rules and definitions. These kinds of writings are thus interrelated, and the relation between them and Tagore's poetry is regarded as quite palpable. The letters by Tagore that have so far been published in book form comprise 11 volumes. He wrote thousands of other letters, which served very well as an effective means of expressing his personal and private musings and thoughts, his dreams and visions on a variety of subjects and issues that interested him. He also wrote a large number of essays and addresses on a variety of subjects, kept a diary of his extensive travels, and even wrote several textbooks for the boys and girls of his *asrama* schools. As if all these were not enough, in 1912 he completed a series of essays that were later delivered as lectures at Harvard University and published as *Sadhana* (The Realization of Life). In 1917 *Nationalism* and *Personality* were published, which contained his lectures and addresses delivered in Japan and the United States in 1916; and in 1922 *Creative Unity* was published containing his occasional essays and other lectures delivered abroad.

During the stretch of six decades, Tagore had interludes of stagnation as well. Many times the poet's muse started to falter, but not for long. He had comparatively few sterile periods, though he had produced enough to make a writer famous. Constant travel, intense financial struggles, public addresses, and a ceaseless crusade for a new outlook were distractions

hardly conducive to meditative or creative moods. Besides these preoccupations and pressures, it has been noted that at times the poet lost to the prophet, the singer to the preacher, and thus the resultant cyclicality.

The last 10 years of Tagore's life opened a new phase of creativity: new but not inherently unconnected from his earlier phases. Tagore felt certain that for him poet-nature was not his sole function in life. It was through painting that Tagore found the release that he could not quite achieve in poetry. Tagore recalled the Indian theory of creation as play (*leela*) and claimed that he was beating the creator at his own game and creating forms that missed their chance in actual existence since God did not provide a place for them. Thus his recourse to another aesthetic medium helped the poet fill in the lacunae in his poetical work. From 1928 to 1940 he painted more than 2000 pictures apart from his other work, his travels, the ever increasing calls on his time, and the darkening crises of the 1930s.

As if Tagore could not have achieved permanence through his ceaseless creative activity in literature, music, and painting, his energy found expression in the experimental work that he undertook in the field of social reconstruction and the ideas and ideologies that inspired and motivated them. Rehabilitation of village and rural economy, the cooperative movement, working out new principles and methods, and evolving a national system of education, ideas and speculations on the contemporary political life in India and on nationalism and internationalism—these were again a part of his mind and personality. His creative vision prompted him to ask questions about God, life, and death, and to answer them by evolving a religion of man. Tagore sought to give tangible form to his ideas on education and socioeconomic reconstruction by establishing and funding institutions like *Santiniketan* (Abode of Peace) and *Sriniketan* (Institute for Rural Upliftment). For Tagore, this enterprise was not unrelated to that of the creative writer and artist. It was intimately related to his total creative personality and spiritual being. He described *Vishvabharti* (World University) as his “tangible poem.”

From 1912 to 1932 Tagore undertook 10 foreign tours and lectured in major cities of Europe, Asia, and North and South America. He lectured on the problems of power, militarism, war, and the decay of civilization through the human search for comfort and a consumer culture. A considerable part of these travels and sojourns was taken up by his attempts to collect funds for his school at *Santiniketan* (Abode of Peace), which had become a financial worry to the poet. Tagore's lecture tours abroad were an economic necessity for his school, but they were also a psychological necessity for Tagore. Like his many other creative endeavors, his travels also provided him opportunities to “know the full meaning of my birth as a human being in this world.”

Tagore had other reasons to travel, which made some observe that he was not only a constant international traveler but a traveler in internationalism, which he had adopted as his most cherished cause. It is not surprising that Tagore has been called “conspicuously bicultural.” Tagore's progression toward selfhood and an attempt at the realization of the infinite was not smooth. From 1878 to 1941, he continuously worked at full pressure, and though we may not enjoy all his works, we have to note the flagging of his inspiration on

occasions. We cannot trace the growth of his genius only up to a certain point, but have to discover the peaks scattered all over those 60 years. Tagore scholars feel that even his failures are more worthwhile than the success of many writers. The poet in Tagore grew slowly, stage by stage, and not in a flash. Years of formal discipline and layers upon layers of experience would have to follow before he could articulate himself convincingly.

Mahatma Gandhi called Tagore *Gurudev* (Revered Master) and he attained a certain classicality. His works have universal appeal and that illuminates his complexity and “myriad-mindedness.” His unique humanism is reflected in a statement Darwin’s granddaughter made to a friend after meeting Tagore: “I can now imagine a powerful and gentle Christ, which I never could before.”

Talent and Creativity

J Piirto, Ashland University, Ashland, OH, USA

Glossary

Creativity ‘To make new.’ What is made does not necessarily mean to make something completely unique, but to continuously operate on the edge of current knowledge to grow and evolve to the next level. Creativity research focuses on the person – who is creative?; the process – what happens when one is being creative?; the product – what does the creative person make?; and the press – what is the environmental pressure on person, process, product? One approach judges a product ‘creative’ and then looks at the person who has produced that product, to see what forces operated in the creation of that product, what that person is like. Another approach tests a child through paper and pencil or through observation, pronouncing him or her potentially or really more creative than others, on a presumed normal curve of creativity, as a construct which supposedly exists within everyone to some degree or another.

Giftedness A confusing term that sometimes means having a high IQ and sometimes means having an inborn talent. Because of the confusion, people often conflate giftedness with talent, and the term is used coequally with the term *talent*, as in ‘talented and gifted,’ and ‘gifted and talented.’

Talent As a noun. “The natural endowments of a person; a special often athletic, creative, or artistic aptitude; general intelligence or mental power: ability; a person of talent or a group of persons of talent in a field or activity.” *Merriam Webster Dictionary Online*. <http://www.merriam-webster.com/netdict/talent>

Talent development ‘Talent’ as an adjective: the process by which a person with a certain natural endowment or propensity in a recognized or becoming domain is taught, shown, and mentored toward the skills that are required by practitioners in that domain.

Introduction

The word *talent* originated in Latin, and it was the term for a sum of money. As the term evolved, it came to mean an inclination, a leaning, a desire, a wish. Its first use in the contemporary sense of having a natural ability or a mental endowment evolved from the Gospel of Matthew, in his story of Jesus’ ‘Parable of the Talents.’ According to the *Oxford English Dictionary* (3rd Edition, 1981), by 1600, the word was used as we use it today: The writer W. Watson said “Silly bodies and sorie fellowes of no talent gift or ability.” To be talented is to possess the skills or proclivity to do something well. The question is whether talent is innate, and how innate propensities for adult achievement can be developed, or whether talent is the end product of high intelligence, or ‘g,’ known as giftedness.

The word *creativity* means to make new, and it is a relatively new term, coming into common parlance in the 1960s. When someone possesses talent, he or she uses this to create a product, whether it be concrete or ideational. A long literature exists which is too complex to be cited in this small entry. One of the seminal works in the current consideration of how talent development leads to adult creativity was the work of Bloom in 1985, who considered the developmental stream that led to adult creativity in various domains including music, sculpture, mathematics, and science.

Models of Talent Development and Creativity

Taylor’s Multiple Talent Approach

In 1968, Calvin Taylor, one of the early creativity researchers, developed a model called the Multiple Creative Talent Teaching Approach, later renamed the Talents Unlimited Model (TU).

He named nine areas, and these were developed into teaching modules that were used in the 1970s, through a series of federal grants. The nine areas were broken down into thinking skills called ‘talents’- academic talents, productive thinking talents, and talents in planning, communicating, forecasting, decision-making, implementing, human relations, and discerning.

Talent Search Model

In the 1970s, Julian Stanley began to give the Scholastic Aptitude Test to moderate and bright middle schoolers. The highest scorers were viewed as having the highest potential for mathematical achievement, and were given special coursework and accelerated through the lower schools to permit them to enter college early and to pursue a Ph.D. He founded a program called the Study of Mathematically Precocious Youth (SMPY). The model was expanded in the 1980s to include verbally talented middle schoolers as well. The high scorers have been followed since then by Stanley and Benbow, and over 40 years of data have resulted. Their findings have indicated that specific paths of education and mentoring are necessary for the development of talent. These include advanced courses and special programs. Talent Search centers exist at Northwestern University (Midwest Talent Search), Johns Hopkins University Center for Talented Youth (CTY), which recruits from the east and abroad, and the Talent Identification Program (TIP) at Duke University, among others.

Feldman’s Model

Another developmental approach has been to look at prodigies as Feldman has done, in the belief that looking at rapid talent development will provide knowledge about all talent

development. In 1997, Feldman proposed a theory of talent development leading to creativity called *Nonuniversal theory*, which concerns the development of the intellect that explains “transitions and transformations in understanding and extending bodies of knowledge, acquisition of expertise and creative advances in knowledge.” Feldman proposed a continuum of developmental domains: (1) universal; (2) pancultural; (3) discipline-based; (4) idiosyncratic; and (5) unique.

Olszewski-Kubilius Model

Olszewski-Kubilius developed a psychosocial model for the development of the creative person that takes into account *Context*: Family Characteristics, Child Characteristics, Family Status (e.g., socioeconomic status (SES), marginality), Birth Position, Family Generational Influences, Physical Disabilities (domain preference and resources), Asynchronies in Child, and Gender; *Conditions*: Stress (parental loss, harsh parenting, parental dysfunction, neglect, abuse), Threat to Security, Feeling Out-of-Control, Isolation, Rejection, Feeling Different, Reduced Affiliation and Identification with Parents, Disruptions in Socialization, Unconventional Socialization, Need for Refuge, Emotional Disequilibrium; and *Characteristics*: (which include Intellectual Activities such as a rich fantasy life, voracious reading, skill development, and coping strategies for isolation). Creative people compensate for developmental defects and lacks, ‘seeking to relieve loss, obtain love and admiration,’ and the ‘need to find controllable situations, optimal situations,’ and a ‘discovered life theme’ that could be described as ‘transformational coping’ that will ‘express childhood traumas.’ The creative work helps the person to ‘cope with tension/marginality,’ and gives the person ‘freedom from conventionality.’ The work is ‘tension reducing,’ ‘soothing,’ and gives the person the ‘opportunity to explore fields,’ the ‘ability to take risks,’ the ‘desire to stir up the status quo,’ and to ‘search for asynchronies.’

Expertise Theory

Another avenue of talent development is the research on expertise. This is domain – or discipline – based and includes research on transfer. How do children master the subject matter? It is content-specific and context-bound. Research on expert – novice comparisons has shown that experts have a large knowledge base of patterns in how the domain works. They can rapidly recognize situations where the patterns apply, and they can therefore reason forward, manipulating the patterns in order to reach solutions. Expertise researchers such as Anders Ericsson often say that talent does not mean much at all, but that deliberate practice is the key to human achievement and to the ultimate product that is judged creative by expert judges. Most of the research has been done on domains such as music and athletics. Motivation is key, not talent. The ‘ten year rule,’ from this theory is that a person reaches mastery after at least ten years of deliberate practice.

Gardner’s Multiple Intelligences Theory

Another theory of talent is the theory of multiple intelligences (MI). Project Spectrum, a joint effort of Gardner’s colleagues

Mara Krechevsky of Harvard’s Project Zero and David Feldman of Tufts University, engaged in studying children and developing assessments for these intelligences. Founded in 1984, Project Spectrum researchers set out to determine whether or not children as young as four years old had ‘distinctive profiles of intelligences.’ These eight intelligences are linguistic, spatial, mathematical, musical, naturalist, bodily kinesthetic, interpersonal, and intrapersonal. Gardner claimed that each of these types of intelligence is discrete, and is formed by its own peculiar kinds of learning, as well as its own kind of memory and perception. His decision to call these intelligences instead of talents was key to the ensuing success of the theory, he said. He proposed eight criteria for the discrete existence of an intelligence, including isolation by brain damage, an evolutionary history, psychometric support, and the existence of savants and prodigies.

Mainstream educators have demonstrated a substantial interest in Gardner’s work. Articles about his theory have appeared in most mainstream educational journals. Workshops conducted by educational consultants are available throughout the country. Colleges of education teach undergraduates about multiple intelligences. Thus, Gardner’s theory has transformed the educational landscape. Educators have always known intuitively that children are intelligent in many ways, and not just in the mathematical and verbal ways that are usually tested. The eight intelligences are assessed by looking directly at the intelligence as it is manifested, and not by abstract paper and pencil testing.

Feldhusen’s TIDE Model

Feldhusen saw talents as being genetically induced, with those who will demonstrate talent showing that talent in precocious behavior. Motivation, style, and ability are environmentally influenced. Insight, knowledge, and skills in thinking creatively are essential in the realization of specific talents. Feldhusen said there are four domains of talent with specific subcategories: (1) academic/intellectual; (2) artistic; (3) vocational-technical; and (4) interpersonal/social, and that children differ in their talents and in their levels of talents, that the heritability element is simply potential and not manifestation of talent, and that talent development is the business of the schools.

Gagné’s Model of Giftedness and Talent

Francoys Gagné calls talent an end product created by the interaction of aptitudes and certain catalysts. Many definitions in English assume talent is inherited and can be developed. Gagné, a native French speaker, calls giftedness what is inherited and talent what results. He has delineated many general fields where talent (the top 10% in terms of demonstrated skills) lies. Among these are talents in academic, technical, artistic, interpersonal, and athletic fields. Giftedness, on the other hand, is the aptitude for achievement in these fields. He sees gifts as the raw materials, the building blocks, of the systematically developed skills typical of a given talent field. The domains of giftedness are intellectual, creative, socioaffective, and psychomotor. There are three categories of catalysts: (a) intrapersonal (e.g., personality characteristics, motivation, volition); (b) environmental (e.g., family, milieu, provisions,

events); and (c) the chance factor. Gagné created qualitative subcategories that recognize other gifts, for example, socio-affective gifts (e.g., precocity and the ability to negotiate), creative talents (the ability to improvise in any of the arts), or technological and mechanical talents (e.g., the ability to fix machines). He thinks that there are fields where talent is needed other than the usual professional fields such as medicine, law, and education. Such fields would be those such as cooking, gardening, popular music, teaching, sales, social work, and electrical work. The concept of talent should embrace more domains – a talented cook is a chef, for example, just as a talented academic is a professor. Gagné's model has had significant influence on the latest thinking in the field of talent development.

Simonton's Emergent–Epigenetic Model

Dean Keith Simonton has proposed that many complex talents operate according to an emergent–epigenetic model. This model begins by defining talent in terms of a set of inheritable abilities and traits that facilitate the acquisition and manifestation of domain-specific expertise. In other words, talent is defined by a multidimensional profile. The question then arises of how these inherited traits and abilities are combined. One very interesting possibility is that the inheritance is multiplicative rather than additive. Multiplicative inheritance means that the abilities and traits are configurational or emergent. If any one component of the profile is missing, the talent does not exist. Hence, if talent is emergent, then a large proportion of the population will not display the talent. Moreover, the distribution of the talent will be highly skewed, the most talented residing on the extreme upper tail, heads and shoulders above everybody else.

Simonton then assumes that the abilities and traits do not manifest themselves all at once but rather develop over the course of childhood, adolescence, and early adulthood. It is this developmental aspect that makes complex talents not just emergent but also epigenetic. This gradual unfolding of genetic endowment also has several consequences. For example, a person's talent is not a stable attribute but rather may transform into another talent. A child prodigy at the piano might convert into a composer, and then later become a conductor. In addition, because the person's profile of abilities and traits is changing, it becomes more difficult to identify a person's gifts, especially in childhood. And, finally, this developmental instability means that education and training must be carefully moderated to keep in step with these changes. Simonton's emergent–epigenetic model is best suited for understanding complex talents such as choreography or architecture. It would be less useful for understanding intellectual talent, as defined by a high general intelligence.

Piirto Pyramid of Talent Development and Creativity

When one looks at the development of talent, one notices certain patterns that are common to those who enter the same field. I have called these *predictive behaviors*, for even early in life, practitioners of creativity in a certain domain have undertaken certain practices that are common. Talent is recognized through certain predictive behaviors. These are well known to practitioners and experts in the domain, and

they are the gatekeepers and judges of whether a talented person is talented enough to enter the domain. Coaches of athletics know this (body type, dexterity, physicality, etc.). Musicians know this (matching pitch, dexterity, tonal quality of voice, etc.). Each domain has its predictive behaviors that are, for the most part, evident in childhood. This article uses the Piirto Pyramid as a framework for discussing the creative person in the domains of visual arts, architecture, creative writing, science, mathematics, invention, entrepreneurship, music, theater, dance, and athletics.

The emotional aspect: personality attributes

Many studies have emphasized that successful creators in all domains have certain *personality attributes* in common. These make up the base of the model. These are the affective aspects of what a person needs to succeed. These rest on the foundation of *genes*. Among these are *androgyny, creativity, imagination, insight, introversion, intuition, naiveté, or openness to experience, overexcitabilities, passion for work in a domain, perceptiveness, persistence, preference for complexity, resilience, risk-taking, self-discipline, self-efficacy, tolerance for ambiguity and volition, or will*. This list is by no means discrete or complete, but shows that creative adults have achieved effectiveness partially by force of personality. Talented adults who achieve success possess many of these attributes. These aspects of personality are present in some way in highly creative people. One could call these the foundation, and one could go further and say that these may be innate but to a certain extent they can also be developed and directly taught.

Personality is sometimes equated with character, directing how one lives one's life. The personality attributes mentioned here have been determined by empirical studies of creative producers, mostly adults, but in some cases, adolescents in special schools. Empirical means that the researchers gave personality tests to the people and also observed them and interviewed them. Many of the personality attributes have focused on the Myers–Briggs Type Indicator, The Cattell 16 Personality Factors, The Eysenck Inventory, the Gough Creative Personality Inventory, the California Psychological Inventory, the Minnesota Multiphasic Psychological Inventory, and others. Recently, the Big Five Personality attributes (Neuroticism, Extraversion, Openness, Agreeableness, Conscientiousness) and the ten facets within each attribute, have subsumed these other indicators, and more research is coming out with this instrument and gifted and talented populations.

The cognitive aspect

The *cognitive* dimension in the form of an IQ score has been overemphasized in accounting for the presence of creativity and talent. The IQ is a *minimum* criterion, mortar and paste, with a certain level of intellectual ability necessary for functioning in the world. Having a really high IQ is not necessary for the realization of most talents. Rather, college graduation seems to be necessary (except for professional basketball players, actors, and entertainers. Most college graduates have above average IQs but not stratospheric IQs).

Talent in domains

The *talent* itself – inborn, innate, mysterious – is specific and may include certain physical attributes as well as mental

qualities necessary to be creative in each domain, and every talented person needs education in the ways of the domain. Each school has experts in most of the talent domains that students will enter. Some of these domains are *mathematics, visual arts, music, theater, sciences, writing and literature, business, entrepreneurship, and economics, athletics, dance, the spiritual and theological, philosophy, psychology, and the interpersonal, and education*. They are all quite well-defined academically, and people can go to school to study in any of them. When a child can draw so well they are designated the class artist, when a child can throw a ball at 85 miles an hour, when a student is accused of cheating on a short story assignment because it sounds so adult, talent is present. These talents are demonstrated within domains that are socially recognized and valued within the society, and thus may differ from society to society.

Environmental 'suns'

These four levels could theoretically be called the individual person. In addition, everyone is influenced by five 'suns.' These suns may be likened to certain factors in the environment. The three major suns refer to a child's being (1) in a positive and nurturing *home* environment and (2) in a *community and culture* that conveys values compatible with the educational institution, and that provides support for the home and the school. The (3) *school* is a key factor, especially for those children whose other 'suns' may have clouds in front of them. Other, smaller suns are (4) the influence of *gender*, for there have been found few gender differences in personality attributes in adult creative producers; and (5) what *chance* can provide. The presence or absence of all or several of these makes the difference between whether a talent is developed or whether it atrophies.

However, although absolutely necessary, the presence of talent is not sufficient. The asterisk, or 'thorn' on the pyramid exemplifies that talent is not enough for the realization of a life of commitment (see [Figure 1](#)). The entire picture of talent development ensues when a person is pierced or bothered by a thorn, the *daimon*, that leads to commitment. However, the person who possesses the talent also must possess the will and fortitude to develop the talent. The talented person recognizes that the thorn is pricking and the call must be answered. Here is a brief overview of themes found in common domains.

Themes in Creative Domains

Domain: Visual Arts

- **Genetic Aspect.** The families of Calder, Renoir, Wyeth, Picasso, Georgia O'Keeffe, and Maurice Utrillo, are examples of visual arts being the family occupation. This was more common in earlier centuries than it is now.
- **The Emotional Aspect: Personalities of Visual Artists.** Personality studies by Barron in 1968 and Mackinnon in 1978 have shown that visual artists care little about social conformity, have a high need to achieve success independently, are flexible.
- **The Cognitive Aspect.** In 1983, Gardner wrote that the intelligence of visual artists is spatial intelligence, or as Vincent Van Gogh said, "It is at bottom fairly true that a

painter as man is too much absorbed by what his eyes see, and is not sufficiently master of the rest of his life."

- **The Domain 'Thorn' in Artists.** Art is a vocation, a 'sacred calling,' and one who heeds the call has a certain character, besides the interest and the talent. The decision to commit their careers to making art – to being artists – comes gradually and progressively. The young class artist begins to think of going to art school.
- **Sun of Home.** There are no outstanding demographic patterns in the families of artists. As many fathers professionals as blue collar workers. Families were both encouraging and discouraging.
- **Sun of Community and Culture.** Cross-fertilization and cross-cultural influences among artists is common (e.g., Matisse and Picasso). Artists do not create in a vacuum. For example, Picasso's repeating theme of the Minotaur had a profound influence on Jackson Pollock.
- **Sun of School.** In school, they showed intense drawing and the emphasis on products, on making the drawings realistic and recognizable representations.
- **Sun of Chance.** In order to enhance their chances of emittance, they must rent or buy a loft, move to an art center such as New York City be in a juried art show – try for a one-man/woman show, and/or get a Master of Fine Arts (MFA) and try to become an art professor.
- **Sun of Gender.** Women are and have been less likely to become well known artists. Women are more likely to go into art education than into fine arts.

Domain: Creative Writers

This domain has been explicated in 2002 in a book-length study by Piirto.

- **Genetic Aspect.** Whether or not there is a writing gene is not known. Few writers come from families of writers, but some do: Andre Dubus and his son Andre Dubus II; John Cheever and his son and daughter Ben and Susan. Screenwriters and novelists Nora and Delia Ephron are the daughters of Hollywood screenwriters.
- **The Emotional Aspect: Personalities of Creative Writers.** (1) Independence/nonconformity; (2) drive/resiliency; (3) courage/risk-taking; (4) androgyny; (5) introversion; (6) intensity or overexcitabilities (7) naivete or an attitude or openness; (8) intuition (N); (9) perceptiveness (P); (10) energy transmitted into productivity through self-discipline; (11) ambition/envy; (12) concern with philosophical matters; (13) frankness often expressed in political or social activism; (14) psychopathology; (15) depression; (16) empathy; (17) a sense of humor (most humorists are first writers).
- **The Cognitive Aspect: Intelligence of Creative Writers.** Writers usually score very high on verbal intelligence sections of the IQ tests, and not so high on spatial and mathematical.
- **The Domain 'Thorn' in Creative Writers.** Why write? Because one can't not write. The writing is not for fame, money, or notoriety, but to fulfill a more personal need, the need to find out what one is thinking, the need to put it down so that it can be dealt with, the need to codify emotion.

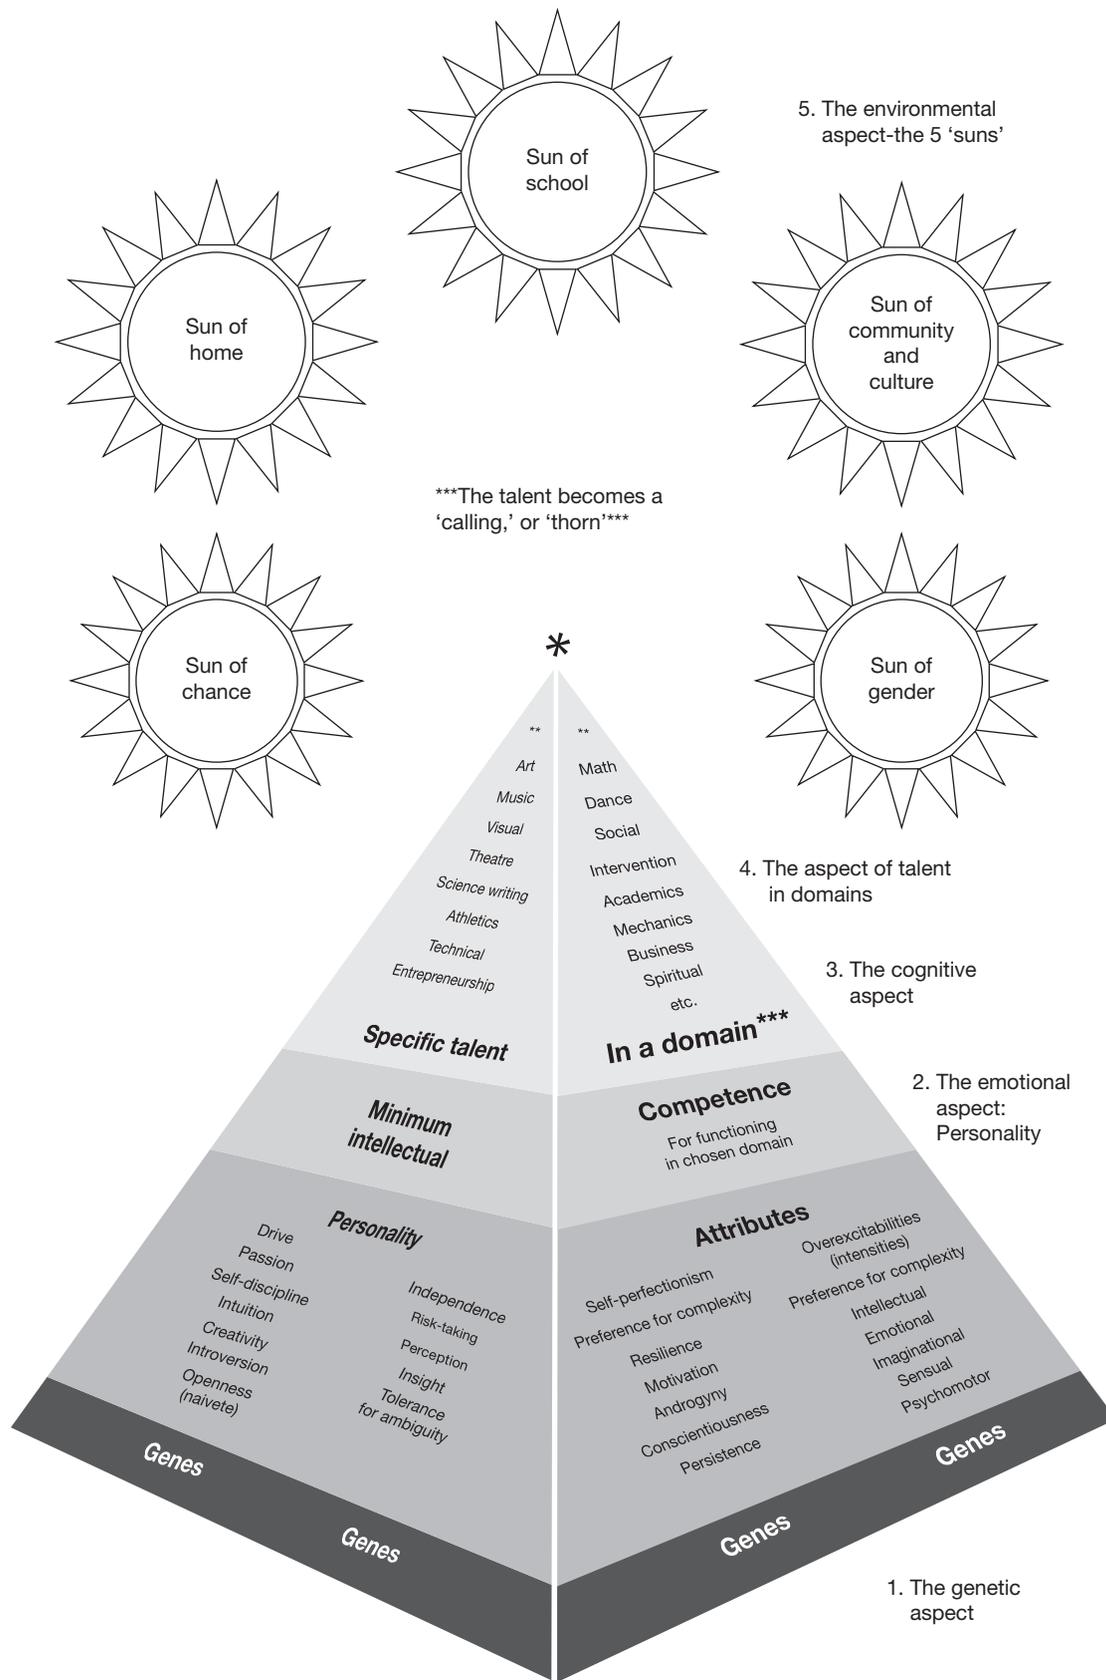

Figure 1 Piirto © 2010 Piirto's Pyramid of Talent Development first appeared in *Talented Children and Adults* (1994). It was subsequently revised in 1998, 1999, 2002 and 2004. This is Version 6.

- *The Environmental Suns* have been reduced to sixteen themes, as follows:
- *Sun of Home*
 1. Predictive behavior of extensive early reading.
 2. Predictive behavior of early publication and interest in writing.
 3. Unconventional families and family traumas (e.g., parental alcoholism, moving often, death of a parent, uncertain finances). This includes the search for the father, as in writing families, the fathers are often viewed as weak or ineffectual.
 4. Incidence of depression and/or acts such as use of alcohol, drugs, or the like.
 5. Being in an occupation different from their parents.
- *The Sun of Community and Culture*
 6. Feeling of marginalization or being an outsider, and a resulting need to have their group's story told.
 7. Late career recognition.
- *The Sun of School*
 8. High academic achievement and many writing awards.
 9. Nurturing of talents by both male and female teachers and mentors.
 10. Attendance at prestigious colleges, majoring in English literature but without attaining the Ph.D.
- *The Sun of Chance*
 11. Residence in New York City at some point, especially among the most prominent.
 12. The accident of place of birth and of ethnicity forms the subject matter.
- *The Sun of Gender*
 13. Conflict with combining parenthood and careers in writing.
 14. Societal gender expectations incongruent with their essential personalities.
 15. History of divorce more prevalent in women.
 16. Military service more prevalent in men.

Domain: Scientists and Mathematicians

- *The Genetic Aspect.* There is some evidence of heritability in families of scientists. For example, take The Darwins – Erasmus, Sir George Howard, Francis Galton, Sir Francis Darwin, Sir Horace Darwin, George Galton Darwin, Josiah Wedgewood, Thomas Wedgewood, and the Huxleys – Sir Andrew Fielding Huxley who won the Nobel Prize, Sir Julian Huxley, biologist, and Aldous Huxley, a novelist who wrote science fiction (*Brave New World*).
- *The Emotional Aspect: Personalities of Scientists and Mathematicians.* Creative scientists had personalities similar to artists and writers, except that the scientists had more emotional stability than the artists and writers.
- *The Cognitive Aspect: Intelligence of Scientists and Mathematicians.* They receive high scores in mathematics and in spatial ability on IQ tests. Scientists use mathematics as a tool. Mathematicians find joy and fulfillment in the beauty of mathematics for its own sake, or the elegance of the proof. Scientists want to unlock the secrets of nature,

and they are motivated by their beliefs in underlying universal themes or patterns in nature.

- *The Domain Thorn: Passion for Science and Mathematics.* Biographical studies by Piirto in 2004 show they have passion for doing the work and persistence in doing it. As children, they incorporate their science interest into their play with collections of rocks, insects, spiders and the like.
- *Sun of Home.* They come from more stable homes than other creators, especially writers. The father presence as an influential force. Simonton indicated that firstborns and only children make up more than half of active scientists.
- *Sun of School.* Scientists and mathematicians often skip grades in school, and take the most challenging courses. They list their favorite courses as mathematics and science.
- *Sun of Community and Culture.* Many scientists come from immigrant populations. In fact, the current shortage of US-born mathematicians and scientists has led to special modifications in immigration requirements. In the twentieth century, many scientists came from a Jewish background.
- *Sun of Chance.* The phenomenon of serendipity often applies. Serendipity can take place when a person has tried and tried to solve a problem but has failed until a universal characteristic becomes apparent; when a chance discovery truly happens; when an unanticipated find occurs; when an entirely different problem is solved; or when someone is tinkering and just seeing what happens.
- *Sun of Gender.* As Simonton said in 1999, "In the annals of science, fewer than 1% of all notables are female. Names like Hypatia, Caroline Herschel, Marie Curie, and Barbara McClintock are but drops in a sea of male scientists".

Domain: Inventors

- *Emotional Aspect: Personalities of Inventors.* They demonstrate the core attitude of Naiveté, and the ability to focus quickly. They show high self-confidence and high self-esteem. They also demonstrate risk-taking, a willingness to troubleshoot and to plunge in.
- *Cognitive Aspect: Inventors.* They demonstrate spatial (figural) intelligence.
- *Sun of Community and Culture.* Inventors Hall of Fame inductees since the 1960s have been what MacKinnon called Captive inventors in 1978, those hired by a university or a company. A Ph.D. is common (physics, biochemistry, ceramics, chemistry, engineering).
- *Sun of Gender.* Inventors inducted into the Inventors Hall of Fame were overwhelmingly male. They hold many patents, not just the ones for the invention for which they were inducted.

Domain: Entrepreneurs

Entrepreneurs such as J. Paul Getty, Bill Gates, Ted Turner, and Warren Buffett came from rich or very comfortable families; they had access to expert advice and legal protection of their ideas; they were readers and thinkers; they were smart in mathematics (e.g., Bill Gates scored 800 on his SAT); and

they liked money from an early age. In 2010, Gladwell wrote that: contrary to popular belief, they are not especially risk-takers, but conservators of their family money and 'predators.'

Domain: Musicians, Composers, Conductors

- **The Genetic Aspect.** We don't know whether there is a music gene or music genes, but music talent does seem to run in families, for example, the Mozart family, the Mendelssohn, the Bachs, the Dylans (Bob and his son Jakob) and the Simons (Paul and his son Harper).
- **The Emotional Aspect: Personality attributes.** Studies with the 16 PF have shown how various practitioners in music (performers, composers, conductors, classical musicians, popular musicians) are alike and different in personality. For example, male composers are aloof, dominant, sensitive, controlled, imaginative, and self-sufficient, while female professional composers are dominant and self-sufficient.
- **The Cognitive Aspect: Musical intelligence.** Appears early in spontaneous singing, chanting, creating sounds with instruments, imitating songs, remembering songs heard, interest in playing.
- **Talent in the Domain: The Thorn.** Music is the expression of deep emotion. Conductor Herbert Blomstedt said, "After a concert I feel exhilarated and want to do it again. I never get tired of making music." Conductor Esa-Pekka Salonen said, "Sometimes I have these funny moments of joy. I'm studying the score and I suddenly realize how great the music is, and I'm overcome by very powerful feelings of euphoria."
- **The Sun of Home.** The family of the musical talent most often has a keyboard instrument. The families are amateur musicians who perform music at home as pleasure, and who listen to music together. They also attend concerts of other musicians. The Sun of Home in rock and popular musicians is less stable, less supportive in terms of lessons, less tolerant of practice, and less full of encouragement.
- **Sun of School.** One must audition and constantly practice, and take lessons from ever more advanced teachers. The master teachers expected discipline and commitment. Being a student of a master teacher means more than just taking lessons; it means adopting a style, a sense of musical repertoire, and a raising in standards of musicianship and performance.
- **The Sun of Community and Culture.** As in other domains, the importance of hanging around with other musicians and artists cannot be underestimated. Cross-influence often takes place in artistic communities, where musicians, visual artists, writers, dancers, and actors hang out together. To illustrate, consider New York City in the 1950s and 1960s, where artists such as Andy Warhol, Bob Dylan, Robert Mapplethorpe, and others met and influenced each other.
- **The Sun of Chance.** The talented musicians, as in other domains, must be ready for chance to strike. For example, take the story of Leonard Bernstein and of Esa-Pekka Salonen. Both were assistant conductors who got their big chance when the maestros under whom they worked had to miss a concert.
- **The Sun of Gender.** 'Lookism' is alive and well in the music domain. Ella Fitzgerald was called too ugly to front a band. Janis Joplin was voted Ugliest Man on Campus. Anne Sophie Mutter is known for her sexy album covers, as is Lara St. John, so much so, that the women bemoan ever being taken seriously as classical musicians. Mama Cass almost didn't make the Mamas and Papas because she was overweight.

Domain: Physical Performers (Actors, Dancers, and Athletes)

- **Actors: The Genetic Aspect.** Families of actors exist, and have existed for ages. Take, for example, the Bernhards, Barrymores, Booths, Sheens, Fondas, Redgraves, and Houstons.
- **Actors: The Emotional Aspect: Personality Attributes.** Psychometric studies have shown the preference for ENFJ (Extraversion, Intuition, Feeling, and Judgment), for resilience, and a tolerance of ambiguity.
- **Actors, Dancers, Athletes: The Intelligences: Cognitive aspect.** These physical performers show what Gardner (1983) called bodily-kinesthetic intelligence, interpersonal intelligence, and intrapersonal intelligence.
- **Passion for the Domain: The Thorn.** As in other domains, the passion must drive the performance.
- **Sun of Home in Actors.** The biographies show family turmoil and/or Bohemian families, for example, the Phoenixes, the Downeys, the Fiennes. Poverty was also present in many theatrical families.
- **Sun of School: Actors.** Actors have a large dropout rate, mostly from university, some just short of graduating, like Brad Pitt and Steve Martin. They are practical, and want to learn the craft, not the liberal arts. Even though, in the United States, there are more than 80 master's degree programs, 300-plus bachelor's degree programs, and several hundred nondegree conservatory programs, many actors do not finish school.
- **The Sun of Chance: The look.** Unfortunately, in the theater, talent is preceded by looks, at least in the United States. "Getting a good head shot is as important as studying with the best teacher," said a theater artist I interviewed. The best singers and dancers, not the best actors get roles in musical theater.
- **The Sun of Chance.** 'Good genes,' said Jane Fonda, when she confessed she no longer exercises very much. Sophia Loren's chest got the attention of Carlo Ponti, and the rest is history. Ava Gardner's looks got her her first jobs. Family connections also matter in enhancing the chance.
- **The Sun of Gender.** The issue of women having to be thin and beautiful and young in order to be performers is present, to a greater extent than for men, though it is present there as well. "Let's hear it for the fat girls!" shouted Camryn Manheim when she won an Emmy. However, she and only a few others such as Kathy Bates are permitted to be overweight.

Domain: Dancers and Athletes

- **Personality Attributes: The Emotional Aspect in Dancers and Athletes.** Personality studies of dancers and athletes have

shown that they have the ability to cope with and control anxiety, confidence, mental toughness/resiliency, sport intelligence, ability to focus and block distractions, competitiveness, hard work ethics, coachability, and high levels of hope.

- **Domain Thorn – Athletes.** “Baseball drove me. It pushed me.” said Derek Jeter in his autobiography. “I was in love with basketball. I couldn’t wait for school to be over so I could run right over to the Stadium,” said Hakeem Olajuwon in his.
- **Sun of Home: Dancers and Athletes.** These creative performers had parents who were willing to pay for lessons and the intense training necessary. They also may have felt the necessity to move the whole family in order to find the perfect coach (as in tennis, ice skating, and gymnastics). Even choreographer Alvin Ailey’s mother, in poverty-stricken Texas, encouraged him to move to Los Angeles to pursue his interests. Male dancers often experience the disapproval of their fathers of their choice of dance.
- **Sun of School.** Sports camps, special schools for various sports, are attended by aspiring athletes. Hour after hour is spent shooting hoops, keeping a soccer ball in the air, practicing plays and moves. They practice, practice, practice to the point of automaticity.
- **Sun of Community and Culture.** The importance of the ensemble, the team, and the group is key in this domain. No one achieves on his own without help from the group. These groups have initiations, rituals, and exclusionary practices.
- **Sun of Chance.** Again, the ‘luck’ of having the right physical makeup for the dance or sport cannot be underestimated. Dance and each sport have its physical requirements.
- **Sun of Gender.** The personality attribute of androgyny in athletes at the top levels has been studied. Male and female athletes at elite levels (on national teams) are remarkably similar in personality. They have high achievement motivation, high tolerance for pain, are highly competitive, and are able to train with great intensity.

These, briefly, have been a few examples from several domains of talent, organized according to the framework of the Piirto Pyramid of Talent Development.

Glossary

Accommodative thinking Thinking that seeks to build new ideas in response to new information (contrast with assimilative thinking, which seeks to maintain existing ideas).

Antipathy to creativity Teachers' dislike of creative students and/or of their behavior and personal characteristics.

Blocks to creativity Factors both within the individual and also in the external environment that block the expression of creativity (contrast with facilitators of creativity, which encourage its expression).

Creativity-facilitating general teaching and learning methods Special approaches to teaching that are particularly likely to promote students' creativity.

Creativity fanaticism Excessive enthusiasm for creativity on the part of parents, resulting in driving or forcing children to be 'creative.'

Differential diagnosis of creativity Procedures for identifying special strengths and weaknesses of particular children so that they can be given appropriately focused

creativity training (see, for instance, 'stifled' creativity, 'abandoned' creativity, or 'frustrated' creativity).

Half-life The period of time it takes for a piece of knowledge or a special skill to become only half as useful or effective as it used to be.

Metacognition Thinking processes that permit control, selection and evaluation of one's own thinking.

Omnivalence The capability of seeing links among large numbers of apparently different ideas.

Pseudocreativity Blind departure from the customary; simply being different.

Quasicreativity Generation of novelty without regard to practicability.

Sputnik shock The surprise and dismay experienced in western countries in 1957 when the Soviet Union successfully launched the first artificial earth satellite.

Technology of creativity training An organized series of activities combined to form a creativity-facilitating package or program to be used regularly for training creativity according to a schedule.

Introduction

The idea of deliberately attempting to foster creativity in the classroom initially aroused controversy and opposition in the 1950s and 1960s. It was argued, for instance, that creativity is by its very nature mysterious and unknowable, and thus incapable of being systematically promoted or fostered, and that attempts to do this were almost sacrilegious. A second argument rested on the assumption that creativity is a special property found in only a few individuals. Some people who regarded themselves as belonging to this chosen group – members of the creativity establishment such as acclaimed writers or critics – argued in a self-important way that ordinary people could never understand their special gifts, and should not try to do so. Some parents and teachers feared that promoting such a rare and highly-prized phenomenon would encourage elitism. There was fear that some children would become the victims of creativity fanaticism among teachers and parents, in much the same way as seems to have happened to some contemporary female tennis stars.

Finally, the association of creativity with highly-acclaimed, sublime products was daunting for teachers, because it seemed to impose on them an even greater responsibility than they already bear. On the other hand, stress on creativity in day-to-day classroom functioning made many teachers and parents uneasy because it seemed to mean encouraging unruly, disobedient, careless, imprecise, or just plain naughty behavior. Some people saw the call for creativity in the classroom as meaning that basic skills, standards, and principles such as correct – incorrect would be abandoned.

However, elitism, fanaticism, sublime products or neglect of basic skills are not the purpose of fostering creativity in the classroom. The desire to foster it derives from a liberal tradition in educational thinking that goes back at least to the Ancient Greeks. This tradition emphasizes that all children should be given the opportunity to develop their potentials to the full, and that education should help prepare young people for the richest and most productive life possible. Modern educational researchers and theorists thus concentrate on aspects of creativity that they believe are present, at least as potentials, in everybody. In other words, appropriate learning conditions can promote some elements of creativity in all children. The purpose of this is not self-aggrandizement or domination of other people, however, but making contributions to the common good.

Why Foster Creativity in the Classroom?

Benefits for the Individual

It is evident that in modern society knowledge and skills have ever-diminishing half lives (the period of time within which 50% of what a person knows or can do will become incorrect or irrelevant). The knowledge and skills needed in the future may not even be known at the time a person attends school. As a result, the school cannot limit itself to the transmission of set contents and techniques, but must promote skills like the ability to adapt the already-known to new situations or to see new ways of dealing with old situations, as well as personal properties such as flexibility, openness, interest in the new, and

courage in the face of the unexpected. These are central elements of a psychological definition of creativity. Such properties help the individual maintain job and life skills in the face of rapid change, and also help cope with the personal challenges of life, especially in the areas of change, uncertainty, or adaptation, and are thus closely connected with mental health. Thus, the fostering of creativity in the classroom is part of efforts leading to the development of successful and mentally healthy individuals.

There is also substantial evidence that a creative approach to teaching has beneficial effects on acquisition of traditional knowledge and skills: A practical demonstration of this is to be seen in the differences in mathematics achievement between Japanese and German and American children in the Third International Mathematics and Science Study (TIMSS): The Japanese were the third best mathematics achievers out of pupils from 41 countries, whereas the Germans were placed 23rd and the Americans placed 28th. Striking for present purposes is that analyses of videotapes showed that whereas the Americans and Germans spent their time acquiring routine mathematical procedures, Japanese students spent theirs learning to invent, analyze and solve problems. In addition to promoting acquisition of basic knowledge and skills, there is also evidence that creativity-oriented teaching (see later) has beneficial effects on pupils' motivation, as well as on their attitudes to school and their self-image. Put briefly, creativity in the classroom helps students learn better and enjoy school more.

Benefits for the Society

The upsurge of interest in fostering creativity that started in the United States after the 1957 Sputnik shock was, however, not set in motion by concerns about individual wellbeing, but by a perceived need of the society for engineers capable of inventiveness and originality, because of fear that the then Soviet Union was gaining the upper hand in the arms and space races. It was thought that most students were being trained simply to apply the already known in conventional, logical ways (as in the TIMSS example of the teaching of mathematics in Germany and the United States just given). The view that societies need to foster creativity in schools for the good of the whole society quickly spread to other countries, and is now widely accepted.

Although the term 'creativity' is strongly associated in everyday English with fine arts, literature, music and the like, the benefits for society are now seen as going far beyond the esthetic/artistic domain: indeed, the original thrust of post-Sputnik calls for fostering creativity in the classroom focused on science and engineering. Ironically, the initial legislation emphasizing creativity in schools in the United States was the National *Defense* Education Act. More recent thinking also emphasizes the necessity of creativity in commerce, business, manufacturing and marketing, government, health, transport, and communications, as well as defense, law-enforcement, and counter-terrorism. In a 2009 speech, José Manuel Barroso, President of the European Commission, identified creativity as essential for collective and individual well-being, long and sustainable economic growth, and answers to the current

financial, economic and social crisis. Business-oriented writers see creativity as the key to meeting the challenges of the early twenty-first century arising from technological advances, social change, globalization, and now the global financial crisis. Creativity is thus seen as capable of contributing to raising the quality of life, easing the burden of manual labor, improving health care, and promoting peace and security. In other words, in addition to its benefits for the individual, creativity is also seen as having an important role in the favorable evolution of society.

What Should Be Fostered?

Creativity as a Psychological Constellation Within the Person

Children only display creativity when, in addition to being able to, they also *want* to and *feel that it is safe to do so*. Thus, creativity arises from a constellation of psychological characteristics including (a) cognitive aspects (knowledge, creativity related skills and abilities; (b) motivation; and (c) personal properties such as self-confidence. **Figure 1** summarizes the psychological dimensions of creativity and represents their interaction with each other and with the environment. Thinking, remembering, knowing, reasoning (cognitive factors) only lead to creativity when the person is motivated to seek the new and is prepared to take the risk of being laughed at and go without the security offered by sticking to the safe and well known. This requires appropriate personal properties such as courage, openness or self-confidence. **Figure 1** presents an oversimplified view in order to demonstrate the main psychological dimensions. In fact, there are interactions within the elements of a psychological domain (e.g., divergent thinking increases the amount of information available, to take a single simple example), and also between domains (e.g., personal properties such as risk taking and openness facilitate the cognitive process of acquiring information and encourage divergent thinking).

These interactions occur within a social context, of which the classroom is most important for the present article. Properties of the classroom context, often referred to as the 'classroom climate,' affect all three intrapersonal areas (information and thinking, motivation, personal properties), as is shown in the figure. Thus, classroom climate involves a fourth dimension, often referred to as 'Press' – the environment outside the individual. The relationship between creativity and the classroom environment is similar to that between creativity and any social environment such as family or place of work. The classroom can foster or inhibit the emergence of the personal prerequisites for creativity such as interest in the new, daring thinking, or openness, but is also itself affected by the personal properties, thinking skills and motivation of the students – openness, adventurousness, and similar characteristics are encouraged by an appropriate classroom climate but also contribute to the emergence of such a climate.

Cognitive Factors in Creativity

Perhaps the best known approach to creativity emphasizes thinking. It arises out of the distinction between convergent and divergent thinking. Effective application of divergent

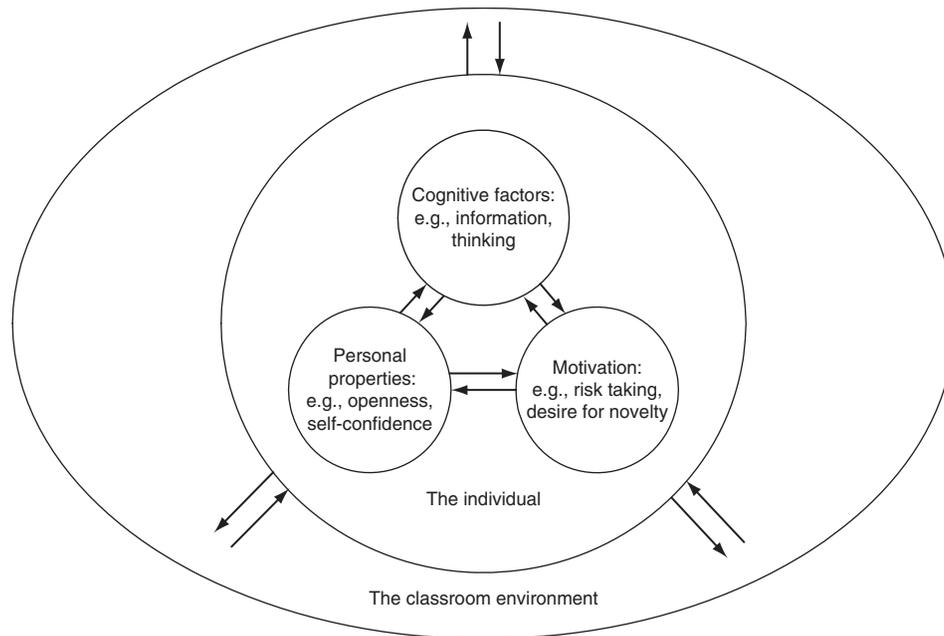

Figure 1 The interaction among personal prerequisites for creativity and classroom environment.

thinking requires information, that is, knowledge of a field. Otherwise creativity has no contents to which it can be applied. Convergent thinking involves applying conventional logic to such information in order to home in on the one and one only best answer it implies – the answer that would in theory be arrived at by anybody who possessed the necessary information and applied the rules of conventional logic. Since the answer is unique and arises more or less inevitably from the available information, in a certain sense it already exists and must only be discovered. In practice, this usually means that the teacher already knows the answer and that students must find out what this answer is.

By contrast, divergent thinking involves branching out from the available information, for instance by seeing unexpected aspects or making unusual associations which others might not notice, or might notice but suppress, for instance because of the risk of attending to them. There are as many answers to be produced from a given set of information as human ingenuity can invent, once attention is directed away from the single, best, correct answer implied by convergent thinking. Although – especially in practical settings where a genuine problem must be solved – some ideas may be more practicable than others, different students may nonetheless come up with drastically different solutions that are theoretically of equal value.

Dean Simonton argued that the making of creative associations is a random process. A person with broad knowledge of a field possesses a large array of ‘cognitive elements’ that can be combined with each other to form ‘configurations’ until a novel and effective configuration (a combination of ideas that meets the requirements of the particular situation) occurs. However, blind associating, in the sense that all possible combinations of all possible kinds are carried out until one of them delivers the hoped for solution, would involve vast

numbers of empty trials unless the person in question employed mechanisms that permitted short cuts, for instance by ruling out whole groups of associations that can be recognized as in principle blind allies, or by indicating that certain lines of attack are very promising. Such mechanisms involve *metacognition*. They permit control, selection, and evaluation of one’s own cognitions.

One approach, based on Jean Piaget’s research on cognitive development, differentiates between ‘figural,’ ‘operational’ and ‘executive’ *schemata*. Figural schemata permit an accurate internal representation of information, operational schemata yield an abstraction and generalization of the information, and executive schemata consist of general principles for transforming information. Creativity is permitted by accurate figural schemata, abstract operational schemata, and flexible, complex, and differentiated executive schemata. A further approach to describing the thinking processes involved in creativity based on Piagetian principles involves a distinction between ‘accommodative’ and ‘assimilative’ thinking. This distinction is important for educators, as it emphasizes that fostering creativity involves both broadening and deepening the existing organization of knowledge in a process of enrichment (assimilative creativity), as well as fostering the building of novel ways of seeing the world (accommodative creativity).

However, teachers should not focus exclusively on creativity. On certain tasks, such as acquisition of facts, students who display high levels of divergent thinking but without accuracy, speed, conventional logic and similar properties may experience particular difficulty. They are sometimes surpassed even by students who are poor at both convergent and also divergent thinking. On the other hand, those students who do best of all in the widest variety of situations are the ones who display both ‘creative’ factors and also speed, accuracy, logic,

and the like. What is needed is rounded ability: originality and similar characteristics accompanied by accuracy, and conventional thinking at appropriate times.

What these findings on the cognitive aspects of creativity mean for teachers can be summarized in the following way. They should strive to promote in their students:

1. possession of a fund of general knowledge;
2. knowledge of one or more special fields;
3. an active imagination;
4. ability to recognize, discover or invent problems;
5. skill at seeing logical connections, overlaps, and similarities, drawing logical conclusions, etc. (convergent thinking);
6. skill at making remote associations, branching out, seeing the unexpected, etc. (divergent thinking);
7. ability to think up many ways to solve problems;
8. a preference for accommodating rather than assimilating;
9. ability and willingness to evaluate their own work; and
10. ability to communicate their results to other people.

Personal Properties

Some theorists have gone so far as to argue that creativity is, in the first instance, *a particular pattern of personality* rather than a set of cognitive factors. Many studies have investigated this view by studying people already acknowledged as creative and have concluded that personal properties such as flexibility, sensitivity, tolerance, responsibility, autonomy and positive self-image are related to creativity. Openness to the new has also been regarded as crucial. Openness involves an interest in novelty for its own sake; the open person simply likes to go beyond the conventional, is spurred on by the unexpected, and seeks alternative explanations for everything.

Descriptions of the creative personality cross the boundaries of gender stereotypes: inspiration is thought of as stereotypically female, for instance, elaboration stereotypically male. In a similar way, sensitivity and responsibility are regarded as female, autonomy and positive self-image as male. Thus, the creative personality is said to involve a mixture of stereotypically male and stereotypically female characteristics. These findings underline the need to break away from gender stereotyping in school programs. For instance, whereas most girls acquire empathy, altruism, and consideration (properties that are favorable to creativity) more or less effortlessly, for instance by learning from models, many boys do not simply 'pick up' such properties and need help to acquire them.

Motivation

Research has shown that creative individuals differ from the less creative in *motivational patterns* too. Among other things, they seek to create new order out of chaos (to accommodate), whereas less creative people seek to return things to the way they were before (to assimilate). A further motivational characteristic of highly creative individuals is their near obsession, with some tasks. They are willing to strive to their mental and physical limits. This requires a fascination with the field and a sense of invincibility, which is greatly strengthened when the drive comes from

within; that is, when motivation is intrinsic. The motivational prerequisites for creativity include (a) curiosity; (b) willingness to take risks; (c) tolerance for ambiguity; (d) dedication; (e) stamina; (f) fascination for the task. Of these, dedication and tolerance for ambiguity are crucial. Tolerance for ambiguity is so highly developed that it does not involve simply tolerance for two alternatives (ambivalence), but willingness to see that anything could be combined with anything else (omnivalence).

A major question in connection with classroom instruction is that of the effect of rewards such as praise, grades or prizes on motivation for creativity. The dominant view until recently was that such extrinsic rewards cause children to concentrate on behaviors that lead to the rewards, and to cease behaving in the desired way when the rewards stop. Such children are experiencing *extrinsic motivation*, a state of affairs that was thought to be the antithesis of creativity, since it involves reproducing the already known under the direction of others. What writers like Teresa Amabile initially regarded as necessary was *intrinsic motivation*, where children are motivated by their own curiosity and their fascination for an issue, events, a problem or an activity, and are thus encouraged to invent, innovate, and branch out on the basis of their own imagination, fantasy, and the like.

Such findings appear to have profound implications for fostering creativity in the classroom. If external feedback such as grades inhibits creativity, the teacher's role in fostering creativity seems to be limited to encouraging free expression of ideas regardless of quality. Recent findings indicate, however, that the effects of external rewards are not as simple to define as had been thought. Their effects are dependent upon the exact situation and may differ between males and females. Researchers such as Robert Eisenberger have shown that extrinsic motivation can be applied in such a way as to encourage creativity. Highly differentiated external rewards given only for high quality performances have been shown to increase creative activity rather than reduce it. 'High quality' can be defined in terms of the child's own talents, abilities, and skills, and need not involve sublime performances at the level of acknowledged creators. However, the child must know exactly what it is that is being rewarded: If creativity is to be facilitated by giving rewards, the children must have a concept of creativity (even if it is not given this label), for instance, novel ideas, brave speculations, or promising fantasies, and must be rewarded for displaying such behaviors, not simply for being active or unrestrictedly productive, that is, uninhibited.

Creativity research has scarcely concerned itself with the role of *feelings and emotions* in the process of finding effective novel solutions. However, Melvin Shaw showed that a number of feelings such as fascination for the task, self-confidence, frustration when progress is blocked, excitement at the moment of illumination, and satisfaction upon successful verification play a major role. These are all aspects of what might be called 'the joy of creating.' Interestingly, the participants in the study just mentioned made little mention of competitiveness or aggressiveness, perhaps because these feelings are socially undesirable. Creativity seems to be positively affected by feelings such as fascination or excitement, negatively by the feeling of stress.

The findings just presented suggest that teachers should value and promote in their students properties such as:

1. task commitment, persistence, and determination;
2. curiosity and adventurousness;
3. drive to experiment and willingness to try difficult tasks;
4. tolerance for ambiguity;
5. independence and nonconformity;
6. self-confidence and willingness to risk being wrong.

Social Factors

It is important to bear in mind that creativity is influenced by the social setting, in this case the classroom. Various authors have pointed out that being creative means living your life your own way or displaying 'resistance to socialization.' Studies in several different countries such as Israel, the former Soviet Union, and the United States have shown, for instance, that a low level of control can facilitate creativity, although this must be accompanied by warmth and support, as it may otherwise be interpreted as aloofness and lack of concern. Authors such as Robert Sternberg and Todd Lubart have emphasized the role of social factors like norms and conformity pressure in inhibiting creativity. Children learn that certain things are simply not done, and thus acquire general rules forbidding certain lines of action (e.g., "You shouldn't question what the teacher tells you"). As a result, whole classes of theoretically possible solutions are banned *en masse*. Society has 'filters' through which certain behaviors, even certain thoughts, are blocked.

Social factors can, however, also have a positive effect on creative achievement. A study of creative individuals by Benjamin Bloom showed that in many cases a single significant person played a crucial role in their childhood, for instance by making the young person aware of his or her own potential. This was often done by a person such as a grade school teacher who demonstrated passionate interest in a topic and awakened fascination for it in the child, showed a creative youngster that he or she was not alone, or helped the student make contact with peers, experts, or other supportive adults. Despite this, a major aspect of social factors seems to be their powerful role as inhibitors. Thus, in fostering creativity teachers must seek not only to provide releasers, but also to eliminate blockers.

An interesting finding in this regard is that some teachers tend to be more supportive of creative students, so that it is possible to speak of 'creativity fostering' teachers. These teachers often get along well with all students, but are particularly effective with creative students. Darnell Cole, Heather Sugioka, and Lisa Yamagata-Lynch summarized the ways such teachers foster creativity: They provide a model of creative behavior, reinforce such behavior when students display it, protect creative students from conformity pressure from their peers, provide a safe refuge for the students when they are subjected to ridicule or criticism from peers, parents or other teachers, and establish a classroom atmosphere which is supportive of creativity. They are those who:

1. encourage students to learn independently;
2. have a cooperative, socially integrative style of teaching;

3. motivate their students to master factual knowledge, so that they have a solid base for divergent thinking;
4. delay judging students' ideas until they have been thoroughly worked out and clearly formulated;
5. encourage flexible thinking in students;
6. promote self-evaluation in students;
7. take students' suggestions and questions seriously;
8. offer students opportunities to work with a wide variety of materials and under many different conditions;
9. help students to learn to cope with frustration and failure, so that they have the courage to try the new and unusual; and
10. develop a classroom atmosphere that is tolerant of unexpected answers, questions, suggestions, etc.

Promoting Creative Products

Discussions of fostering creativity in the classroom initially saw its products as a matter of uninhibited production of artistic works such as fanciful drawings of a creature from space, or stories of imaginary events such as a journey to the moon. However, writers have paid greater attention in recent years to the idea that creativity should go beyond mere deviation from the usual, and have emphasized that it should lead to appropriate products. An increase in interest in fostering creativity in areas of curriculum such as technological design education or entrepreneurship education – where useful practical products and not just uninhibited flights of fancy are at the core – has also greatly strengthened the modern idea that creativity in the classroom should lead to something concrete and meaningful, not just to flights of fancy. It also encourages the idea that the teaching of creativity is not a 'frill' activity, almost recreational in nature and engaged in perhaps once a week in a special classroom, but a core element of curriculum.

This has increased interest in evaluating creativity, not just as an indicator of a free spirit and the ability to make unexpected suggestions, but in its own right. Related to this is the growing demand for transparency and accountability in evaluation of students' work. The result is that it is becoming necessary to be able to say what makes students' work creative and to help them improve. This requires developing ways of assessing the creativity of products, identifying their strengths and weaknesses in an understandable and stable way, and communicating to students what they are doing right and how to improve what they are doing wrong.

It is obvious that a creative product involves bringing something new into existence, that is, novelty. However, although absolutely essential, novelty is not sufficient on its own. Not every departure from what already exists is creative. Writers have emphasized the need for qualities such as 'correctness,' or 'usefulness.' Such terms clearly involve value judgments, but it does not seem unreasonable for teachers to expect that students' products should be relevant to the task at hand.

A creative product can go further than simply being novel and effective in a specified situation (relevant). It can also be 'elegant.' At its simplest this means that good design solutions look good. Elegance adds value to a relevant and effective solution, and this increases its creativity. In the real world, elegance may mean that a solution is readily identifiable as a

solution, and is accepted, applauded and adopted, while it may also mean that a particular solution defeats a rival solution, for instance in the market-place. Finally, comes 'genesis': the property of a relevant and effective, novel and elegant solution that makes it transferable to different (quite possibly unanticipated) situations. Genesis opens up new ways of looking at known problems, or draws attention to the existence of previously unnoticed problems. In this way, a generic solution goes beyond a 'merely' elegant one and yields the highest level of creativity.

Students' products can be assessed according to the criteria of relevance and effectiveness, novelty, elegance, and genesis. What is needed for doing this, however, are guidelines for teachers that enable them to recognize these criteria when they see them. Hints about what to look for are provided by a number of writers. David Cropley and I have developed a list of criteria (Relevance and Effectiveness, Novelty, Elegance, Genesis) and indicators of the presence of these criteria such as 'correctness,' 'diagnosis,' 'redefinition,' 'reinitiation,' 'convincingness,' 'harmoniousness,' and 'transferability.' Such indicators may be highly subjective, but Susan Besemer and colleagues have shown that people can rate products in terms of subjective criteria with acceptable reliability and a high level of interrater agreement.

Teachers' Attitudes to Creative Students

Antipathy to Creativity

Surveys have shown that teachers appear to overwhelmingly agree in theory that creativity should be fostered in the classroom – a study by John Feldhusen reported that 96% of them expressed this view. However, *in practice* the situation is different. In classrooms many teachers often

- dislike student characteristics associated with creativity, and
- frequently express disapproval or even dislike of the students in their classes who are most creative or score highest on creativity tests.

They often frown upon traits associated with creativity, or even actively dislike characteristics such as boldness, desire for novelty, or originality. Preferred are courteousness, punctuality, obedience, and receptiveness to other people's (the teacher's) ideas. In the area of thinking, high skill in memorization and accurate recall are often preferred to critical thinking or independent decision making. This finding emerged early in the modern creativity era (i.e., in the 1950s and early 1960s), when for instance Jacob Getzels and Philip Jackson reported that teachers expressed a strong preference for teaching 'merely' intelligent children rather than highly creative students. It has been strongly supported by research ever since, right up to the present day, as a recent summary by Elizabeth Mowrer-Reynolds showed.

Paul Torrance concluded that the problem arose from the tendency of creative children to do things like asking unexpected questions or giving unusual answers to teachers' questions. He pointed out that some teachers even went so far as to describe creative children as mentally defective, and concluded that what teachers liked was students who conformed and reproduced material supplied by the teacher or the textbook.

This preference cuts across disciplines, and has been repeated consistently over the years in many different countries including Africa, Asia, Australia, Eastern and Western Europe, the Middle East, and North America. There is a high level of disapproval of schoolchildren asking questions, having the courage of their convictions, guessing, being intuitive in making associations, or taking risks. By contrast, there is near unanimity that school children should be obedient, work industriously, accept the judgment of authorities, and be considerate of others.

It seems that teachers may not understand what creativity really involves. In one study they linked several words associated with mental illness (emotional, impulsive) with creativity. Teachers who were given adjectives describing traits typical of what creative children are actually like (e.g., inclined to take risks, curious, inclined to offer unexpected answers), said they *disliked* such youngsters. In fact, research shows that the students most likely to be rated creative by their teachers are simply the ones the teachers and classmates like best. As Gudmund Smith and Ingegerd Carlsson put it, "... teachers seem to have a confused picture of what is a favorite pupil and what is a creative pupil."

Why Do Teachers Display Antipathy to Creativity?

A major problem for educators is that many of the personal properties discussed above are not conducive to order and discipline in the classroom. Independence, autonomy, and nonconformity associated with quick shifts of attention, fascination for the unexpected and constant search for alternative explanations may not only be disconcerting for the teacher, but may be misunderstood by peers. As a result, children who display such properties may either act as a catalyst for disorderliness or be regarded by other youngsters as beneficiaries of playing favorites by the teacher, who may seem to peers to be tolerating behavior from one student which is not tolerated when classmates behave in (as they see it) a similar way. At this point it is helpful for teachers to remember the distinction between genuine creativity, pseudocreativity (mere blind deviation from the customary) and quasicreativity (generation of novelty without concern about the link to reality), as this makes it possible to recognize and describe the difference between creativity and similar looking misbehavior.

Characteristics associated with creativity include lack of concern for social norms. Studies have also shown that creative children are significantly more introverted, more self-willed, less satisfied and less controlled than children who display lower levels of creativity. In social situations they are less willing to conform and less interested in making a good impression. To put it plainly and briefly, creative students can sometimes seem to teachers to be 'weird,' defiant, aggressive, self-centered, or antisocial, characteristics which make them disturbing, even threatening. Furthermore, for most teachers, transmitting standard knowledge in an easily understood manner is the essence of their job. Their knowledge is their stock in trade, and any student behavior that seems to offer a challenge to it is a serious matter: behavior such as penetrating, unexpected, even challenging questions – no matter how innocently meant – may even threaten teachers' self-esteem. Little wonder that this aspect of creativity arouses teachers' unease or dislike.

Summing up, creativity may sometimes:

- shake the foundations of the received classroom order,
- bring uncertainty for pupils (and parents),
- question the value of laboriously acquired knowledge and skills,
- threaten loss of status and authority for teachers, and
- weaken teachers' self-image.

Can Creativity Be Taught?

But does creativity training work? It is frequently argued that the effects of creativity-facilitating programs scarcely generalize to behavior in settings other than those closely resembling the training procedure itself. However, more recently Ginamarie Scott, Lyle Leritz, and Michael Mumford carried out a more encouraging meta-analysis of 70 studies. Tse-Yang Huang also conducted a methodologically rigorous meta-analysis of 62 empirical studies of the way creativity training influenced the behavior of schoolchildren, university students, and adults. Both analyses concluded that training did foster creativity. The effects were strong in both children and adults and in both educational and noneducational settings (e.g., at work), and in both gifted and nongifted people. This was true for both males and females, although more marked in males. Positive effects were most pronounced when the criterion of creativity involved cognitive processes (i.e., divergent thinking and problem solving). Within the cognitive domain, the single largest benefit of creativity training was greater originality of thinking, although training also enhanced fluency, flexibility, and elaboration of thought.

Of great interest for this section, Scott, Leritz, and Mumford found differences between training procedures in their effectiveness. When cognitive, social, personality, motivational, and combined training procedures were compared, it was found that the cognitive approach produced the largest changes. Most effective in promoting creativity was practice in analytic thinking, that is, processes such as problem identification, idea generation, conceptual combination (linking ideas often kept separate), and constraint identification. The second strongest effect of training was on creative performance (i.e., the products produced after training were more creative). There were also noteworthy changes in attitudes such as dissatisfaction with the *status quo* or willingness to take risks.

Scott, Leritz, and Mumford showed, in a nutshell, that the best way to foster creativity was to give participants opportunities to analyze novel, ill-defined but realistic problems, whereas mere deviation from the usual (pseudocreativity), or unfettered expression of unexplored fantasies (quasicreativity) was actually negatively related to the effectiveness of training. They also found that highly organized and systematic training based on realistic examples and involving substantial periods of structured, focused practice (i.e., relevant to a real field or domain) was most effective. Training should start by introducing relevant general concepts and basic principles, then move to specific skills.

These findings suggest that reality-oriented creativity can be trained. The failure of early efforts to teach creativity may

possibly be attributed to the fact that the training consisted of isolated short bursts of unstructured work on activities that had no connection with real-life settings. The findings of Scott, Leritz, and Mumford suggest five principles for successful creativity teaching. These are:

- Give students targeted practice in solving problems (not for instance simply in generating 'blind' novelty).
- Give students highly organized and systematic training based on realistic examples from the field they are learning about.
- Base the creativity training just mentioned on extended periods of structured, focused practice (not an occasional 'creativity' session).
- Base training on broad knowledge and skills (relevant general concepts and basic principles).
- Move from broad knowledge and skills to targeted practice aimed at acquiring specific knowledge and skills.

Methods for Fostering Creativity

Eliminating Blocks Versus Actively Promoting Creativity

Many theorists believe that creativity is present in all people, especially children, at least as a potential, and that it emerges spontaneously if it is not inhibited or 'blocked.' The basic idea is that children do not need to be taught to think divergently, phantasize, or make remote associations, or to be open, flexible, and courageous enough to take risks and break away from the well known, or to show fascination for the new. They already know how to do this, but are inhibited by learned 'blocks' that make them hide these properties. Fostering creativity is then seen as eliminating such blocks. Typical blocks in the child's own mind include (a) inability to break an existing set, (b) inability or unwillingness to relax control and let ideas flow, (c) inability to handle the flow of ideas, (d) excessive preference for analytical thinking, (e) excessive preference for verbal expression, (f) fear of letting the imagination loose, (g) fear of giving the wrong answer, and (h) desire to answer as quickly as possible. Other blocks are part of the social climate of the classroom. These include (a) exaggerated success orientation, (b) intolerance of questioning, (c) reliance on external evaluation, (d) exaggerated conformity pressure, (e) rigid maintenance of strict sex roles, (f) strict distinction between work and play, and (g) intolerance of differentness. For this group of theorists, fostering creativity is thus principally a matter of breaking down blocks.

The opposing point of view is that people are not naturally divergent and full of fantasy, but need to be shown how to be creative. However, the necessary 'instruction' can be quite simple. For instance merely giving students examples of unusual responses, or simply allowing them to play with test materials or to watch a video of a comedian or of a person solving a creativity test seemed to increase their scores. However, some authors have emphasized the need to learn special thinking techniques such as (a) reversing the problem, (b) considering the end result, (c) focusing on the dominant idea, and (d) discarding irrelevant constraints. Game-like procedures

exist for training such thinking skills, including (a) producing, (b) analyzing, (c) elaborating, (d) focusing, (e) associating, (f) combining, (g) translating, (h) breaking out, and (i) recognizing the new.

Well-Known Techniques and Packages

Among the specific techniques which have become well known and are often available on a commercial basis are Synectics, Bionics, Brainstorming, Morphological Methods, Imagery Training, the KJ Method, the NM Method, and Mind Maps. Of these, Brainstorming has assumed particular importance in business, where it has become probably the most widely practiced set technique. Reduced to the absolute minimum, Brainstorming is a procedure in which participants initially produce answers without particular attention to whether they are practicable or not and all ideas are accepted without criticism. Synectics has similar properties, although it involves special techniques for finding ideas, especially 'making the familiar strange' and 'making the strange familiar'; basically this is a procedure for encouraging the making of unexpected associations.

Many other procedures for training creativity have also been marketed. These may consist of specific, discrete activities such as 'attribute listing,' 'idea matrix,' and 'creativity toolbox,' that sometimes take the form of games such as 'bridge building,' 'idea production,' or 'creative productions.' Sometimes a series of activities are combined to form creativity facilitating packages or programs which are meant to be used regularly for creativity training, according to a schedule. It has become common to refer to such materials (both the discrete activities and the packages) as involving the *technology* of creativity training, in much the same way as the machines in a gymnasium constitute the technology of bodybuilding. The idea is that it is possible, with the help of this technology, to do mental workouts, just as athletes do physical workouts.

The US Patent and Trademark Office compiled an extensive overview of relevant techniques and materials, listing about 25 packages aimed at promoting creative thinking – these packages involved several hundred separate activities in all. About a dozen sets of materials they listed were concerned with fostering critical thinking, once again encompassing hundreds of individual activities. Also listed were materials on fostering decision making, higher order thinking skills, and problem solving. This publication is a valuable source of information on creativity technology. A number of better known packages or programs for fostering creativity are listed in [Table 1](#). This table is an expanded version of a table in Runco, M. (ed.) *Handbook of Creativity* (p. 87) (Hampton Press, 1997).

Particularly interesting for the present discussion are the psychological characteristics the programs in [Table 1](#) aim at promoting. Most give greatest weight to the cognitive aspects of creativity (getting ideas, combining elements of information, etc.), even those which do not specifically see themselves as focusing on creative thinking. Only one program focuses on aspirations and feelings, while another gives some weight to attitudes toward problem solving. This cognitive focus makes good sense in view of the findings of Scott, Leritz, and Mumford mentioned above that the strongest effects of creativity training are to be seen in the cognitive domain.

However, the importance of personality, attitudes, values, self-image or motivation should not be overlooked. There is even a danger that creativity training may simply make children aware that certain kinds of behavior are preferred by the teacher, and lead to them copying this behavior. As a result, they would learn to conform to teachers' wishes rather than to be original. Although children may be encouraged by cognitive training to work hard on a variety of tasks, they may also learn that it is easy to give 'original' answers by engaging in hairsplitting, giving rambling answers without regard to accuracy or relevance, or offering unexpected banalities. Instead of becoming more creative as a result of offering ideas freely and without evaluation, students may simply become less self-critical.

A number of organizational forms have been adopted for incorporating various forms of creativity training into school curriculum. The traditional approaches involve various forms of enrichment. This frequently occurs outside the regular classroom, often involving special 'creativity' sessions conducted by a specialist resource teacher and frequently in a special resource room, the 'creativity center.' In some countries programs for fostering creativity outside the regular classroom involve visits, for instance to art galleries, while special activities such as creativity weekends, creativity workshops or creative vacation camps are now offered, not only in North America but also in Germany and France, among others. Some schools incorporate creativity training into the regular classroom, for instance by having creativity lessons or sessions once or twice a week in the home room. In these sessions, students are usually encouraged to work with unusual materials and to create nontraditional products, quite often in a problem-solving context: For instance to make a model of a rocket ship for mice out of cardboard, string, paper clips, and glue. The product may also be artistic in nature, for instance to draw a picture of the child's nicest experience using paints, crayons, chalk, pencils, colored paper, etc. With older children the emphasis may be on creative thinking, and problem solving is very popular. Such activities are often criticized as being no more than fun and games that have little to do with the goal directed, self-critical work of acknowledged creative people. This attitude has become prevalent in the United States where teachers have been encouraged to focus on basic skills, and teaching to the test has become a common practice.

Differential Diagnosis of Creativity

The creativity enhancing enrichment in a resource room or in weekend seminars or vacation camps often involves only a small group of children who have been selected as showing particular promise. This raises the whole issue of selection: what instruments are to be used, how valid are they, do they discriminate against specific groups on the basis of sex, race, socioeconomic status, physical disadvantage, or other factors? Even where selection procedures are technically sound, the whole idea of selection contradicts the ideal of full development of all children and the view that creativity can be fostered in all children, as well as raising fears of developing a small elite group. Some authors have developed procedures for admitting children to creativity programs that deal with some of these issues, such as the revolving door approach (children pass into and out of the program

Table 1 Main characteristics of well known creativity programs

<i>Program</i>	<i>Level</i>	<i>Materials</i>	<i>Aimed at promoting</i>
Imagi/Craft	Elementary school	Dramatized recordings of great moments in the lives of famous inventors and discoverers	<ul style="list-style-type: none"> ● The feeling that their own ideas are important ● Widened horizons ● Career aspirations of a creative kind
Purdue creative thinking program	Fourth grade	Audiotapes and accompanying printed exercises	<ul style="list-style-type: none"> ● Verbal and figural fluency, flexibility, originality, and elaboration
Productive thinking program	Fifth and sixth grades	Booklets containing cartoons – uses principles of programmed instruction	<ul style="list-style-type: none"> ● Problem-solving abilities ● Attitudes to problem solving
Myers–Torrance workbooks	Elementary school	Workbooks containing exercises	<ul style="list-style-type: none"> ● Perceptual and cognitive abilities needed for creativity
Creative problem solving	All levels	No special materials – makes great use of brainstorming	<ul style="list-style-type: none"> ● Finding problems ● Collecting data ● Finding ideas ● Finding solutions ● Implementing solutions
Talents unlimited	All levels	Workbooks based on idea of ‘inventive thinking,’ aimed at problem solving Emphasis on brainstorming	<ul style="list-style-type: none"> ● Thinking productively ● Communicating ● Planning ● Making decisions ● Forecasting
Khatena training method	Adults and children	No special materials Simple teacher made aids	<ul style="list-style-type: none"> ● Breaking away from the obvious ● Transposing ideas ● Seeing analogies ● Restructuring information ● Synthesizing ideas
Osborne–Parnes program	High school and college level	No special materials Primary emphasis on brainstorming	<ul style="list-style-type: none"> ● Getting many ideas ● Separating idea generation and idea evaluation
Clapham–Schuster program	College level	No special materials Relaxation exercises Definition of creativity as involving combining ideas brainstorming, synectics, etc	<ul style="list-style-type: none"> ● Getting ideas ● Understanding creativity ● Using metacognitive techniques (setting goals, expecting success, coping with failure)
Creative dramatics	All school levels	Exercises involving touching, listening to and smelling common items Pantomime activities such as removing things from an imaginary box Playmaking – acting out stories	<ul style="list-style-type: none"> ● Imagination ● Discovery ● Sensory awareness ● Control of emotions ● Self-confidence ● Humor

according to interest, need, and success) or selection via performance (those who display creativity go into the program) or selection via motivation (all those children who wish to enter the program are admitted).

The psychological model of creativity presented above offers prospects of what can be called a ‘differential diagnosis’ of creativity. It is seen as arising out of the interaction between a number of elements each of which is necessary but not sufficient: knowledge, thinking skills, motivation, personal properties. The classroom is seen as a social setting in which these properties can be fostered or inhibited. **Table 2** shows the various combinations of properties that are theoretically possible. A plus sign indicates that the characteristic in question is strongly developed, a minus sign that it is weak. In order to focus the discussion, only situations where the personal

prerequisites are particularly strongly or particularly weakly developed are presented in the table. As a result, the 16 ‘types’ shown are more or less stereotypes, but they serve here to demonstrate the point clearly.

Column 1 refers to a child possessing all four elements and represents ‘fully realized’ creativity, Column 2 a child in whom the personal properties are absent – ‘stifled’ creativity, Column 3 a child in whom only the motivation is missing – ‘abandoned’ creativity, Column 4 a child without the necessary thinking skills – ‘frustrated’ creativity, and Column 5 a child who lacks knowledge – ‘naïve’ creativity. The patterns shown in Columns 5–8 have in common that the child does not possess the necessary knowledge, that is, they involve various forms of pseudo-creativity. To take a single example of differential diagnosis, it can be seen that a child resembling the profile in Column 3

Table 2 Theoretically possible combinations of the factors involved in creativity

	Possible combinations															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Knowledge	+	+	+	+	-	-	-	-	+	+	+	+	-	-	-	-
Thinking skills	+	+	+	-	+	+	-	-	-	-	-	+	+	+	-	-
Motivation	+	+	-	+	+	-	+	-	-	+	-	-	+	-	+	-
Personal properties	+	-	+	+	+	+	+	+	-	-	+	-	-	-	-	-

(no motivation to be creative) needs a different kind of help from a child resembling Column 2 where motivation and knowledge are present but openness, flexibility, and self-confidence are missing.

Differential diagnosis of the kind just suggested can only occur if appropriate diagnostic instruments exist. This indicates the need for procedures, for instance tests, capable of yielding a profile, rather than a global creativity quotient that attempts to sum up a child's creativity in much the same way as a global IQ summarizes intelligence but loses sight of special strengths and weaknesses. Such diagnosis has no point, of course, unless it leads to differentiated treatment. Thus, a challenge for the theory and practice of creativity in the context of education is the development of instruments capable of delivering profiles and of training procedures capable of fostering development in specific areas. This, in turn, opens up issues in the developmental psychology of creativity, and requires answers to questions such as the timing of the necessary cognitive, personal and social development, the reversibility of developmental defects, and the possibility of critical phases in both development and 'remediation.'

Creativity-Facilitating General Teaching and Learning Methods

Various researchers have developed and tried out special approaches to teaching and learning that can be applied in the classroom in all disciplines and at all age levels, and focus not only on thinking skills but also on motivation, attitudes and personal characteristics. These include:

1. *Discovery learning*: Working alone or in small groups students examine contents to discover hidden or unexpected connections or structures, either physically or, more usually in the form of recurring regularities, categories, rules, or irregularities, incongruencies and problems. For instance, a physics class could tackle the task: In what way are an electric motor and a prism similar?
2. *Play learning*: Play is free of the constraints of the strictly logical. Risks can be taken without fear of real life consequences, rules can be broken, the impossible can be tried out, fantasy can be given free rein. An example could be: Act out a scene showing what would have happened to the Plymouth Brethren when they reached America if the Viking settlement hundreds of years earlier had been successful.
3. *Learning via problem solving*: A gap, difficulty or open question is the starting point for the learning. The problem has to be defined, relevant information collected, and solutions

suggested. The suggestions can be developed in a play-like atmosphere with the advantages listed above, or they may be required to be strictly reality-oriented. In the latter case, the relationship to reality must be managed in such a way that risk taking is not inhibited by the stringent requirements. An example might be: How could you build a perpetual motion machine?

4. *Learning via structural analysis*: A given situation has to be broken down into its constituent elements (in some ways the opposite of discovery learning) and the rules or principles of its structure identified. Suggestions, including fanciful ones, can then be made for ways of changing elements or their connections with each other. English students could be asked: How could you turn *Macbeth* into a comedy?

In all these suggestions, surprising, unorthodox, even apparently absurd suggestions are tolerable and can be pursued. However, the point is not to encourage blind guessing, random answers or ridiculous responses. A child who gave the answer, 'Eat more bananas,' to the question, 'How could you build a perpetual motion machine?' would be asked to explain further.

Closing Remarks

If all children's creativity is to be fostered effectively in the classroom, it seems unlikely that narrow, limited exposure to cookbook creativity-facilitating exercises will achieve the desired effects. Although limitations of space preclude a detailed discussion here, this is especially the case with children from disadvantaged groups and children of low intellectual ability. What is needed is an approach in which all aspects of teaching and learning adhere to basic principles for fostering creativity. Children need contact with complexity, with ambiguity, with puzzling experiences, with uncertainty, and with imperfection. The task for teachers is to challenge children to be open for the novel; to give them courage to think for themselves and to seek the new; to show respect for children and their achievements in order to foster in them self-confidence and high expectations. These tasks involve not only intellectual, but also personal, motivational, emotional, and social aspects of creativity. What is needed was put with great clarity about 100 years ago by the German educationist Wilhelm Rein (I have translated his words with a certain artistic license):

You cannot become creative merely by reading books on creativity. However, simply daubing paint on canvas, making up doggerel or stringing notes together does not make you creative either. Above all, two things are necessary: creative potential on the one hand, and schooling that takes creativity seriously on the other [emphasis added].

Glossary

Diversity The variation among team members in personal characteristics such as expertise and demographic characteristics.

Electronic brainstorming Generating ideas by means of computer systems.

Innovation The development and implementation of new products or ideas.

Interdisciplinary Team collaboration that involves the integration of knowledge or expertise to develop new concepts or approaches.

Multidisciplinary Teams that represent different disciplines working on a common goal.

Production blocking The inability of individuals in groups to express ideas as they occur since only one idea can be effectively expressed at one time.

Psychological safety The feeling that one is free to express one's ideas or develop innovations without fear of negative reactions from one's fellow team members or the organization.

Self-managing teams Work teams that have a large degree of autonomy in how they perform their tasks as a team.

Transformational leader A leader who has a strong vision and inspires followers to take a creative or problem solving perspective to their tasks.

Virtual teams Teams that are typically geographically dispersed but interact through various media to accomplish their tasks.

Teams

Teams are groups of individuals who work together to accomplish a task or series of tasks. Many tasks are accomplished by ad hoc teams brought together temporarily to accomplish a task in a specified period of time such as committees or task forces. Other teams are part of organizations and work together over an extended period of time on a variety of related tasks. One of the key characteristics is that teams are interdependent – that is team members depend on one another for the successful completion of their goals. This often presumes that team members vary in their expertise and have to effectively coordinate their activities to optimize their performance. There is an extensive literature on teamwork that suggests that working as a team can indeed enhance overall performance of tasks including creativity tasks. Although teams are often embedded in organizations and have an extensive history with their fellow team members, much research on creative teams and groups involves interactions on specific tasks during limited periods of time in laboratory settings. This research is similar in scope to that done under the label of group creativity. Studies of longer term creative teams are often in the form of case studies. Much of the research on team creativity involves the use of self-report measures of the processes and the outcomes. This is potentially problematic in that the use of such a methodology may not reflect what is actually occurring in teams. Studies of work teams in organizations that use objective measures are relatively rare. Most studies using objective measures of creativity involve laboratory studies of group creativity. Of course, these laboratory studies may have limited applicability to the understanding of creativity in long-term and specialized teams. However, there is considerable overlap in the findings on innovation in work teams and creativity in laboratory groups. Thus, the results from both areas of study appear relevant to understanding the creativity of teams.

Creativity Versus Innovation

The literature on creativity in teams tends to use the term innovation rather than creativity. This may in part reflect a bias in terminology by researchers in organizational behavior who are trying to appeal to the business world. The world of business and industry is interested in innovation or the development of new products or services that are useful and have a positive economic impact. Just because a product or idea is creative does not mean it is going to be useful. So the criterion of usefulness or feasibility is an important one. However, innovation is also often reserved for implementation of ideas generated during a prior creative phase. Creativity is seen as an exploration phase of generating novel alternatives or solutions, and innovation as a phase of exploiting the ideas toward some useful end. Although it is presumed that different principles govern the different phases, our assessment of the literature suggests that many of the same factors that influence creativity also influence innovation. Successful exploitation or implementation of ideas also requires creative thinking. This thinking may not be as radical or divergent as that in a prior exploration phase but is creative nonetheless. Moreover, in many studies of team innovation, there is not a clear distinction between the exploration and exploitation process. So in our summary of the team creativity literature we will ignore the innovation/creativity distinction, except in our discussion of the phases of the creative process.

Basic Processes

Team creativity involves social interaction and collaboration. That is, team members engage in a variety of social activities in order to complete their tasks. In the early stages they may have

discussions about goals, task distribution, coordination, feedback systems, and compensation. If they are involved in a creative task there is at some point a process of sharing ideas about a particular issue or problem. This may be followed by some evaluation of the different ideas and possible implementation of the most promising ideas. These processes may be repeated in different sequences during the life of the team. The focus of this entry is on the creative or ideational phases of the team process since there is a significant literature on this issue. The initial planning and later innovation stages may involve somewhat different processes.

Theories of collaborative creativity have recognized both the social and cognitive forces that play a role. Some theories have emphasized the cognitive aspects of collective ideation. As individuals share ideas they need to search their memory or knowledge base for relevant information or ideas. When these ideas are shared in a team, they may stimulate others to think about related issues. So collective sharing of ideas should increase the range of topics or issues that are discussed and lead to mutual stimulation of ideas. Of course this requires careful attention to the shared ideas and thoughtful relating of these ideas to the knowledge or memory base of each team member. This may be facilitated by some intermittent opportunities to reflect on the shared information. At the same time, the idea sharing process may provide a social stimulus for increased effort as team members compete in trying to come up with more and better ideas. This would be particularly true if there is some degree to which individual group member contributions can be identified and recognized. It also appears important that team members function effectively to seek help and give help at critical times in the creative process. This process needs to be reinforced by positive experiences in the group and a supportive organizational culture. However, the social context can also hinder the creative process because of concern about deviating from normative group expectations and there may be a tendency for group members to focus on areas of agreement rather than their potentially unique perspectives. A fundamental process in team creativity is the communication among team members and with other teams. This process appears to be strongly related to team creativity, although there is some evidence that too much communication can be detrimental. A high level of communication may distract one's focus on the task or may involve task irrelevant as well as task relevant information. Irrelevant information may make it more difficult to focus on the essential aspects of the task.

Factors Influencing Team Creativity

Much of the research on team creativity has examined the factors that influence the degree to which teams, especially work teams, develop creative ideas, or innovations. The basic presumption is that the composition of the team, the characteristics of the team members, and the task and social context of the team will influence these outcomes. This presumption is consistent with an input-process-output perspective of teamwork. This perspective focuses on the person, team, and context characteristics that influence the team processes that in turn affect the various outcomes such as performance, satisfaction, and team viability. This framework provides a useful

means for organizing the presentation of the major findings. We will summarize the major factors that influence the team processes and the resultant degree of creativity.

Team Member Characteristics

To a large extent the innovativeness of a team depends on the personal characteristics of the team members. The higher the creative ability of the individual members, the higher will be the creativity of the team. Teams whose members who are open to new experiences, extroverted, and have a divergent thinking style are more likely to be creative. It also is beneficial if team members have a positive attitude toward the team. The teamwork literature suggests that it is important for team members to have a range of team relevant skills such as shared leadership, coordination, performance monitoring, and adaptability.

Team Size

Teams can vary greatly in their size, depending in part on their scope and the complexity of their task. Complex and multifaceted problems may require a wide variety of expertise on the team. Since larger teams are more likely to consist of members with diverse perspectives and skills, it is not surprising that larger teams are associated with more innovation. However, large teams may also have drawbacks since they may reduce the extent to which individual members feel accountable or important to the rest of the team. Thus there may be some loss of individual motivation. Moreover, in large team meetings it may be difficult for all team members to effectively contribute because they have to share the available discussion time. It appears that the ability to express one's ideas as they occur is important in one's ability to generate a flow of ideas. This interference effect due to having to coordinate the expression of one's ideas in the group is known as production blocking. Therefore, it may be best to keep the team as small as possible while still providing the range of expertise needed.

Diversity

One of the benefits of bringing team members together on a creative task is to take advantage of their diversity. Diversity represents the variation in personal characteristics of team members. Team members can vary in their demographic characteristics such as race, gender, age, tenure in the organization, personality, status, values or beliefs, knowledge, experience, and expertise. Each of these characteristics may make interacting with other team members interesting, but research has found that most people prefer to interact with people who are similar to themselves. So there may be a social bias to homogeneous groups or teams. In diverse groups, group members may be somewhat uncomfortable in sharing their ideas or perspectives since they may conflict with those of other group members. Groups often like to gain a consensus based on common perspectives, as seen in cases of groupthink in decision-making groups. So individuals in groups may be more responsive to an idea or information which is familiar rather than one that is different or unique. As a result most reviews of the literature have found that overall diversity is not related to enhanced performance in groups or teams. There is

some evidence that demographic diversity can enhance creativity. However, it appears effective tapping of diversity requires that group members have a positive disposition or attitude to interacting in diverse groups and that they are either intrinsically or extrinsically motivated to take advantage of the diverse ideas or information shared by the team. Intrinsic motivation requires a strong personal interest in the creative activity and learning from others. Extrinsic motivation involves social or organizational incentives (such as financial incentives or prizes) that motivate team members to work hard. Under such conditions team members may carefully process or elaborate the shared ideas and information and come up with potentially innovative ideas based on the diversity of perspectives present in the group. However, the type of diversity is also important. It is often assumed that intellectual or cognitive diversity is more likely to lead to team creativity than social or demographic diversity. Diversity that is mostly social such as demographic or value diversity may not have much influence on creativity unless it is relevant to the team task. Thus the development of an advertising campaign for diverse populations may benefit from demographic diversity, but this type of diversity might not have a positive influence on the development of some innovation in healthcare. This type of innovation will probably require people with diverse expertise or experience relevant to that issue. Research suggests that job relevant diversity in work teams is related to creativity while diversity in background or demographic characteristics is not.

Interdisciplinary Teams

The diversity in interdisciplinary teams should be helpful to creativity. Interdisciplinary teams consist of individuals who are experts in different areas relevant to some task or goal. In science this may involve scholars from different disciplines, in technical fields they may consist of people with different expertise, and in work settings they may involve employees from different departments or divisions. The presumption is that for broad problems or initiatives, a broad range of expertise or knowledge will be required. Teams that include individuals that represent these divergent perspectives or areas of expertise will be better able to solve complex problems or come up with creative solutions or ideas. One can make a distinction between multidisciplinary and interdisciplinary teams. Multidisciplinary teams involve team members from different disciplines coordinating their efforts to achieve a common goal. This type of collaboration primarily involves the use of complementary areas of expertise required to accomplish a goal. Interdisciplinary teams require a higher level of collaborative interaction that involves the actual integration of knowledge or expertise to create new concepts, theories, techniques, or approaches that go beyond what was possible in any one of these disciplines. Members of multidisciplinary teams have to effectively coordinate their various contributions to achieve the group goal. They also need to understand each others' areas, and this level of enhanced mutual understanding may allow the team to reach new levels of technical development.

Achieving mutual understanding in interdisciplinary groups may be difficult. Groups tend to focus on areas that they have in common, in part because such common understandings have obvious validity to the team members and provide a sense of

cohesion. It may be difficult for team members to understand each other's unique areas of expertise unless they have broad training or expertise. With the increasing specialization in all areas of science and technology, few have the time or inclination to develop the broad expertise to effectively understand and build on diverse areas. However, it may be sufficient if team members have the basic knowledge to understand the exchanged communications. An important issue for future research is to determine the role of depth and breadth of expertise in the creative potential of interdisciplinary teams.

Interdisciplinary teams appear to function best when the context or relationships among team members enhance the communication processes. So teams whose members are located close to each other physically or who are in the same organization tend to be more effective than those who are at different locations. Also, it appears to be beneficial if the team members have some degree of collaborative 'closeness' in that they communicate frequently and have strong interpersonal bonds. This is most likely to occur if team members have considerable experience in working together effectively. In fact, the team members who are at the center of the information flow and are aware of the distribution of expertise in the team tend to perform best. A major benefit of interdisciplinary teams is that they provide the type of conflicting and diverse perspectives that should increase the chances of creative ideas. These potential benefits are discussed in the sections on diversity and conflict.

Turnover

In most teams members change periodically. Loss of members that have key skills or knowledge can be very detrimental to the functioning of the team. The team can also lose some of its cohesion and may have to redevelop its transactive memory systems (knowing who knows what in the group). Although research on the issue of turnover in teams is limited, there is some research indicating that periodic changes in group members can enhance creativity. The new perspectives provided by a new member could stimulate other team members to think more deeply about issues or reevaluate their ideas. However, in reality this effect will also depend on whether this team member is a creative person who asserts him or herself effectively as a new member of the group. Newcomers in groups may have to first establish social ties with other group members and adopt the group norms before they can begin to have an innovative impact on the other group members. The impact of contributions by newcomers to the team is also enhanced if they share a common identity with the group (i.e., they share a common goal, values or personal characteristics). However, this positive effect may only occur if the newcomer makes high quality contributions.

Conflict

When team members share diverse perspectives, there may be conflicts. Conflicts in teams are generally associated with negative feelings, especially if the conflicts are social in nature. However, it appears that cognitive conflicts that involve differences in perspectives can stimulate creativity. Such conflicts can lead participants to reevaluate their own perspectives,

especially if those presenting the conflicting perspectives are persistent and do so in a way that is not offensive to the team. In fact, exposure to conflicting perspectives may increase the tendency to divergent thinking and affect creativity on tasks totally unrelated to the setting in which the conflict was experienced. Apparently, the experience of divergent perspectives increases the extent to which a person is willing to consider alternative perspectives in general. Even though cognitive conflicts can increase creativity among group members, overall performance of the group may not increase. Cognitive conflicts may have negative emotional effects which can inhibit the types of interactions required for the overall effective performance of the team.

Safety

One of the key factors in fostering a creative atmosphere in a team is psychological safety. This is the extent to which group members feel that they can express their thoughts and ideas without fear of negative reactions from their fellow team members or the organizational leadership. When participants have this kind of feeling, they are more likely to share their unique and possibly controversial ideas. In a similar vein, research has found when there is an element of trust among the participants involved in a creative enterprise, creativity is more likely to flourish. Trust represents the feelings that others care about one's well-being and one can count on their support even for the 'risky' activities that may be involved in creative work. In fact, the emotional support for one's creative activities from both fellow workers and from family and friends are important for enhancing creative performance. So team members need to trust one another and to support one another in their creative activities. This does not mean that all the innovative ideas expressed have to be accepted or carried out. However, team members should feel that their creative ideas will get a fair hearing from the team.

Another important source of support is the organization within which the team is embedded. Unless the organization and its leaders support creative activities by the team, the team will not have an incentive to be creative and will not feel comfortable in sharing novel ideas for improving the organization and its various projects. Although psychological safety appears to be necessary for creative teamwork, it needs to be balanced with appropriate levels of accountability. In an 'anything goes' environment team members may be tempted to loaf and may drift in their task focus. Some degree of task structure and specific goals may be needed to keep team members on track.

Cohesion

A psychologically safe environment is likely to be one where team members have positive feelings about one another. Such positive feelings are an important component of group cohesion. Group cohesion is the extent to which group members are attracted to the group and its goals. Cohesion can consist of feelings of interpersonal liking, task commitment, and group pride. Not surprisingly these factors have been associated with enhanced performance in groups and teams. Cohesion should enhance creativity since team members feel comfortable with

one another and are motivated to achieve the team goals. They should not be inhibited in sharing their unique perspectives and should work hard to integrate these perspectives to come up with a novel solution. Cohesion may take some time to develop, so positive effects may not be evident until the team has been together for a period of time. However, long-term teams that are cohesive may not necessarily be optimal for creativity. There may be pressure to maintain the positive team feelings and to act in accord with the group norms or expectations. This may inhibit the sharing of novel perspectives that are contrary to the dominant views of the team. Thus it may be important to balance team cohesion with some degree of membership turnover and active contacts with experts outside the team.

Task Structure

Creativity is generally seen as an unstructured activity in that the participant should be as unconstrained as possible by reality, task structure, and time. There is in fact considerable evidence that periods of time without distractions or other demands can facilitate creative achievements. This is particularly true for individuals who have a strong intrinsic motivation for their creative pursuits. Research has shown that it is important for such individuals to have a high degree of autonomy or freedom in their task activities. Increasing task constraints and applying external pressure for task achievement may in fact reduce such intrinsic motivation and creativity. Autonomy also tends to be important for teamwork. Much research has shown that teams that are self-managing, in that they have a choice in their tasks, task processes, and team procedures, tend to function better than those that do not have such autonomy. Similarly, team autonomy appears to be related to enhanced creativity.

Although autonomy and freedom appear to be important for creativity, some degree of structure may also be helpful. It helps to have clear goals and objectives. The team can collaborate in setting such goals, but there may be some tendency to set 'attainable' goals rather than challenging goals to avoid the experience of failure. It should also be clear the goals are for creative production. If the organizational context provides psychological safety, group members may feel it is 'safe' to select ambitious goals. These goals can vary in the extent to which they emphasize originality and feasibility or applicability. Although mutual goals of innovation and feasibility can be seen as conflicting, some research indicates that such dual goals can in fact be quite effective in promoting both originality and the generation of feasible products or ideas.

Although external pressures or incentives can reduce creative motivation, this is not inevitably the case. When these external forces are seen as external control, it may lead to reduced intrinsic motivation. However, when the external forces are perceived as confirming one's competence or enabling one to do an intrinsically interesting task, they may actually increase overall motivation. Competition within the team or with other teams may be one such external motivator. Performance feedback or the provision of challenging goals may have similar positive effects on the creative production of teams. In addition to having some 'directive' social contexts, the task context is also important. In particular it appears that it

is useful to have some degree of task structure. Breaking a task into its subcomponents, providing brief breaks during long idea generation sessions, and providing clear instructions about how to efficiently share are important in increasing the number of ideas generated.

Therefore, in order to increase team creativity, intrinsically motivated group members should be given a high degree of autonomy and time to perform the task without distraction. The development or provision of clear, challenging but attainable goals, performance feedback, and intra- and intergroup competition can increase motivation without decreasing intrinsic motivation. Although many see creativity as an unstructured activity, certain procedural guidelines (e.g., breaks) can improve team creativity.

Training

Although there has been considerable research on training creativity, there has been very little systematic research on the training of group or team creativity. While experience in creative groups may be beneficial, it may also lead to the development of task procedures which are not beneficial to enhancing team creativity (such as the amount of time spent in group interaction). Although the creative process in a particular team may appear to be quite successful, team members typically do not have a clear basis for assessing how effective they have been. Research that has used control groups as a reference point has found that providing groups training that includes practice and the reinforcement of efficient sharing strategies can increase the quality of ideas generated.

Leadership

It is typically presumed that groups need leaders for effective performance. There is a massive literature on leadership in general and considerable data on leadership for groups. Group leaders may be external such as bosses who assign tasks to teams. Teams may also have internal leaders who are actually members of the group. These leaders may be assigned, elected, or may simply self-select to this position in the absence of any clear structure. In general, it appears that team creativity can be enhanced by leaders that provide a clear vision or goals, provide support for innovative activities, and develop a climate in which team members feel it is safe to explore creative directions. It appears that both task oriented leadership (structuring the task, setting goals, directing interaction) and relationship or participative oriented leadership (concerned with good relations and encouraging personal initiative) can enhance team innovation. Participative leadership may be most helpful in the early idea generation stages of the innovation process while the task oriented leadership may be more helpful in the implementation phase. Many studies find that the most effective leader for creative teams would be a transformational leader. These leaders provide individual mentoring, encourage challenging old assumptions, and inspire by sharing their vision and setting high expectations. Teams may also exercise 'self-leadership' if they have considerable autonomy. Such leadership may take the form of shared leadership with different members leading different aspects or phases of the task. Such shared leadership requires effective skills in knowing how to

allocate task components and when to switch leaders. Teams will need some extensive experience or training to develop such adaptive routines. This may involve 'coaching' group members to optimize motivation, task allocation, and appropriate alignment of task routines with task requirements.

Summary

Team creativity appears to be influenced by a broad range of factors. Teams composed of members with certain personal characteristics and task and creativity relevant skills may be most creative. It can also be beneficial if teams have sufficient members, diversity of task relevant expertise, and some degree of turnover in membership. Team cohesion and a degree of psychological safety can also enhance creativity. To attain an optimal level of creativity, teams will need some degree of task structure, training, and effective leadership.

Implementation of Ideas

The process of generating ideas in teams is often followed by an implementation or innovation phase. Creative thinking involves coming up with a number of novel perspectives, but innovation involves selecting one of these perspectives for actual implementation. Innovation requires a process of selecting the best or most feasible ideas for implementation. This may involve a different skill set than that involved in divergent thinking. In fact, ideas that are rated as novel also tend to be rated as less feasible. So it might be best if the innovation process was not conducted by those who actually came up with the idea but by those who have a good sense of what it takes to successfully implement and/or market a particular idea. So an organization might have a team of creative types for generating novel ideas and a team of more technically oriented implementers. This makes sense from the perspective that one can select members for teams depending on their strengths and skills. Team members who score high on creativity do indeed function more effectively in creative teams. In contrast, individuals who are good at evaluating the feasibility and applicability of alternatives may be best suited for development teams. However, in reality the creativity and innovation phases may be difficult to separate. Implementation also requires a good degree of creativity to come up with an effective product or process. In addition, if there are some problems in the implementation stage, it may be necessary to take a fresh creative look at alternatives. Some of the research we have cited indicates that groups can be quite effective with the joint goals of originality and feasibility. Future research will need to determine more precisely the conditions under which separation of creativity and implementation is more effective than a mixing of these phases.

Electronic Brainstorming

With the increased availability of digital means of communication such as email, cell phones, and computer networks, there is much potential for creative collaboration by electronic means. If group creativity is construed primarily as a process of mutual cognitive stimulation, electronic communication

should be as effective as face-to-face communication. In fact, research on electronic brainstorming in which participants share ideas by means of various group information sharing systems has found that electronic exchange of ideas can be more effective than face-to-face exchanges, particularly for large groups. This may reflect the fact that electronic exchanges avoid the production blocking inherent in face-to-face settings. One potential disadvantage of electronic exchanges is that it may be more difficult to build cohesion when the interacting members are working from distant locations. Interpersonal ties may be important in motivating interactions among group members and may facilitate understanding of each other's ideas. Electronic interactions also vary in the richness of interaction modalities. Some may be limited to written exchanges of information while others may involve visual and auditory interactions through the use of video technology. Richer technologies may allow for more effective communication of meanings since they provide for the exchange of various linguistic and paralinguistic cues.

Virtual Teams

There has been an explosion of the use of virtual teams (VTs) in organizations. Like other teams, VTs are comprised of multiple individuals who have some degree of task interdependence, shared goals, and work within an organizational setting. Unlike other teams, VT members are geographically dispersed and rely on technology to communicate. VTs are often distinct in their ability to develop some way to archive the shared ideas and information for later review and the ability to expand the team as needed through electronic means. However, in most ways the creative process in VTs seems to follow similar patterns and processes as co-located teams. There also is often a mix of face-to-face and virtual interaction in such teams. Initial ideation sessions tend to be face-to-face, maybe in part to develop some level of bonding or cohesion. During the development stage, teams tend to work electronically. Evaluation activities are typically done face-to-face. There is not much research to establish whether these are optimal practices. Research with electronic brainstorming suggests that in contrast to VT practice, ideation may be best done electronically. However, this literature supports doing evaluation or decision-making face-to-face.

VT members need the same general skills, knowledge, and attitudes as their co-located counterparts, but also need to have the ability to use technology. Training in such skills has been found to be beneficial. One potential advantage of the VT may be that it can minimize some of the negative emotional reactions observed in face-to-face groups for teams high in demographic diversity. Demographic differences should be less salient in virtual interactions. Thus the information may be processed without regard to interpersonal differences. However, there may also be conflicts about preferred modes of communication among individuals from different cultures. For those from high-context cultures the meaning of messages is determined through an understanding of the context in which it is presented. People from low context cultures primarily focus on objective or factual information in the exchange. Thus communication rich

technologies may be required for effective interactions with individuals from multiple cultures.

Although VTs may not have much in-person interaction, feelings of connection or cohesion still appear to be important. Highly creative VTs tend to have a high level of involvement with and commitment to the group task. It is also important for a VT member to have some sense of psychological safety and trust in their colleagues in order to enhance creativity. Conflicts in VTs may have negative effects that may be hard to resolve without a chance for personal interaction. Thus it is possible that it may be more difficult to observe beneficial effects of cognitive conflict on creativity in VTs.

Summary

Team creativity is influenced by a range of cognitive and social factors. Team members need to be highly motivated and to carefully process the shared information or ideas in order to develop creative products. Teams need both autonomy and some degree of structure and goals to function at a high level. A psychological safe environment, participative or transformational leadership, and training appear to facilitate creative team performance. Implementation of creative ideas also seems to benefit from some of the same factors, but groups may not be particularly effective in selecting the best ideas for implementation. Diversity, conflict, and turnover of membership can both facilitate and hinder creativity. Electronic exchanges of ideas among team members can be quite effective. Studies of virtual teams suggest that they may have some unique features but that their performance is governed by the same factors as conventional teams.

Our review suggests that there is no simple recipe for creative teamwork. Many of the factors we have discussed can have both positive and negative effects depending on their level or other factors. In general there seems to be support for a sort of 'balance' perspective. Teams should be large enough to do the job, but as small as possible. Some degree of diversity, conflict, and turnover can increase creativity, but too much will backfire. Psychological safety and cohesion are important, but too much may make the team members too comfortable with the *status quo*. A high degree of autonomy may motivate creativity in teams, but without some degree of structure, external goals and effective leadership, the team may not accomplish much. Some degree of virtual interaction among team members may facilitate the exchange of information and ideas, but face-to-face sessions may be needed to deal with more complex problem solving and decision aspects of the creative process. So organizations that foster teams will need to be sensitive to balancing these various dimensions to optimize the creative performance of their teams.

Glossary

Affective disorder Depression severe enough to warrant a psychiatric diagnosis.

Depression A mild emotional state, formerly known as melancholia, which does not warrant a psychiatric diagnosis.

Personality disorder A psychiatric diagnosis involving a chronic maladaptive lifestyle which impedes the individual's success or happiness.

In a study of creative women by David Lester in 1993, he noted that suicide seemed to be especially common in female writers and artists. Did these women commit suicide because they were *women*, because they were *creative*, or because they were *creative women*? It is not because they were women since men engage in fatal suicidal behavior at a much higher rate than do women, although women do engage in nonfatal suicidal behavior at a much higher rate than do men, as discussed by Lester in 1984.

Suicide may be more common in creative women because they are *both* creative and women. It may be that the path of the woman who chooses to be creative is far less easy than that of a man making the same choice. The opportunities may be fewer for creative women, the prejudice against their work greater, and their rewards fewer. In his study of 1993, Lester compared six creative women who completed suicide with six creative women who died from natural deaths. He found that the suicidal women were affected by the reception their work received. Dora Carrington appears to have lost confidence in her ability as a painter, Sylvia Plath had just published her first novel to luke-warm reviews, Sara Teasdale was experiencing severe writer's block, and Virginia Woolf was acutely anxious in the time leading up to publication of her novels and often received negative reviews.

It was also clear that depression, both of psychiatric proportions and of moderate intensity, played a role in almost all of the suicides. Diana Arbus, Sylvia Plath, Anne Sexton, and Virginia Woolf had affective disorders, while Sara Teasdale was depressed, and four of them had made previous suicide attempts (Dora Carrington, Sylvia Plath, Anne Sexton, and Virginia Woolf).

The life of Sara Teasdale (based on a biography by William Drake in 1979) illustrates some of these issues.

Sara Teasdale

Sara Teasdale was born on 8, August 1884 in St. Louis, Missouri. She was the fourth born, with a brother George aged 20, a sister Mary (Mamie) aged 17, and a brother John aged 14. She was christened Sarah Trevor Teasdale, but later dropped the final "h". At home she was known as Sadie.

Sara's father had intended to study law but went into business at the age of 17 after his father died suddenly. He had been

successful, ending up as a wholesaler in dried fruits, beans, and nuts. He met his wife at the Third Baptist Church, where they were married in 1863, and they remained devoutly religious. At Sara's birth, her mother was 40 and her father was 45. Sara was almost like a grandchild in the family, only five years older than the first grandchild.

The dominant parent was her mother. Like her daughter Sara, she had a sickly childhood but became transformed upon marriage. Now she was an energetic and domineering mother. Sara's biographer speculated that to have had a daughter at the age of 40 was unseemly in Victorian times. It advertised the fact that she and her husband still engaged in sexual intercourse. Her determination to bring her daughter up as the model of gentility was possibly an attempt to compensate for this shadow on her virtue.

Sara was watched over anxiously from birth and had an early tendency to frailness. She was never strong, got colds easily, and was easily exhausted. When she caught a cold, she was treated as if she had pneumonia and put to bed. For much of her life, her family hired a nurse to be with her to ease the burden of daily tasks and see that Sara did not overtax her strength. Drake suggested that this concern for her led to Sara's life-long anxiety about her health. Her mother crippled Sara by her kindness and lavish concern. Sara's sickness was not a *cause* of her lack of energy but rather it was a *result* of Sara trying to suppress her energy.

Sara was not exceptionally beautiful, and she always regretted this. She was indulged, surrounded by luxuries, given whatever she needed, and excused from household responsibilities. Sara never cooked, mended, or cleaned house. Sara was a placid, sweet-tempered, and obedient child who learned to inhibit her hostile impulses. Drake reprints a photograph of Sara at age five, looking cute for the photographer, but clenching her right fist by her side, perhaps to help her suppress her inner feelings.

Sara was taught at home until she was nine. Thereafter, she attended private schools. Her parents discouraged her from playing with other children because of her frailty, and she became rather shy. At school, Sara did not go to parties, engage in athletics, or have typical teenage fun. She was asked to be on the commencement program, but she declined the honor.

Although her parents were not especially interested in literature, Sara soon developed a passion for it, and her older brothers and sisters encouraged her poetic gift. The schools she attended gave her an excellent education in literature and

the arts so that, even without a college education, Sara was well-read and informed.

The Young Adult

At school, Sara made several close friends and, after graduation, this group formed the nucleus of a group of women interested in the arts. They called themselves the Potters, and they decided to produce an artistic monthly magazine containing their literary and artistic efforts. Each month they produced just a single copy of *The Potter's Wheel*, from November 1904 until October 1907, a total of 36 issues in all. The group also wanted to improve their skills, and so criticism was encouraged. Sara's poems first appeared in print in this magazine, and her first published book of poems contained many of these poems. From the beginning, Sara was very conscientious about her writing and distressed by flaws in her poems. She worked hard to improve them and relied on her associates for constructive criticism.

Friendship with women continued to play a major role for the rest of Sara's life. In the Potters, Williamina Parrish played a prominent role, helping her organize the poems for her first collection. The women in these years played a nurturing and guiding role, taking the place of her mother in supporting her, and Sara always seemed to need one of them to help her complete a book of poems (after Williamina Parrish, there was Marion Stanley, Jessie Rittenhouse, Marguerite Wilkinson, and finally Margaret Conklin). Later, however, she became less dependent upon them, and her final friend (Margaret Conklin) was more like a servant/daughter to Sara. In Sara's early years her heroes were women – Sappho, Guenevere, and the modern Eleonora Duse. Nonetheless, she also needed fantasy male figures for her love poems. Until she was age 28, though, the lovers about whom she wrote poems were almost entirely imaginary.

In 1905, Sara and her mother took a trip abroad for three months. By the time the boat reached Greece, which for a long time had fascinated Sara, she was ill with a fever. But she managed a little sight-seeing and recovered enough to visit the Holy Lands, Egypt, Italy, Paris, and London. Sara enjoyed the trip immensely and took many trips abroad during the rest of her life.

The fame of *The Potter's Wheel* spread through the literary circles of St Louis, eventually reaching the attention of William Reedy who ran the *St Louis Mirror*. He included a piece by Sara for the first time in May 1906, and her pieces in the *Mirror* soon began to establish her reputation as a lyric poet.

In 1907, *Poet Lore* accepted one of her sonnets and later that year produced a book of poems for her which her family had to subsidize. Reviews of the book, in *The Saturday Review* of London for example, were favorable. In 1908, she had a poem accepted in *Atlantic Monthly*, and Putnams brought out a book of her poems in 1911. Reviews in *The New York Times* and *Current Literature* praised it, and she became a member of the recently founded Poetry Society of America. From the first, Sara had the tenacity to submit her work again and again to periodicals until it was accepted. She shrewdly sent copies of her books to supportive reviewers, and she cultivated friends in the literary field.

Sara continued to live at home, in a suite of rooms on the second floor, with a door isolating her from the rest of the

house. Friends did not drop in on her casually. Rather, close friends had fixed, scheduled meetings, and their visits were kept brief so as not to overtax Sara's health. There were two main sides to Sara: this distraught, sickly person who withdrew into isolation versus a witty, intelligent, and candid companion. However, this latter social side appeared only with those whom she knew well, and Sara preferred to develop new relationships through exchanges of letters.

There is no evidence that Sara was especially sickly. She had illnesses and fevers to be sure, but perhaps no more than the average person. When she involved herself in social activities, she experienced desires in her that she could not cope with. At this point, she would retreat into exhaustion and sickness and withdraw to a clinic or a hotel away from everyone to reorganize herself. Sara herself once wondered whether, had she been born into a poor family, she would have had better health! More likely, if she had not been so suppressed as a child and so repressed as an adult, she would have had no need for retreating into sickness.

In both 1908 and 1909, Sara's health continued to be poor, and so she spent some time in San Antonio and at a hospital in Connecticut hoping to recover. Thereafter, when life became too much for her to handle, she escaped to this hospital under the guise of being sick. In San Antonio, she made the acquaintance of another poet, Marion Stanley, with whom she developed a close friendship. Marion tried to get Sara to see herself honestly and to get out of the path of sickliness she had entered. However, even though every visit back home to her parents and St Louis brought on depression (and a desire for death) and a retreat into the patient role, Sara did not appear to have the strength to leave home and try to build a healthy life for herself. Sara was overwhelmed by the aggressive vitality of her mother, and the patient role was how she and her mother had learned to relate to each other in a semblance of a loving relationship.

In 1909, though, Sara decided that she did not want to live at home with her parents forever, especially with her domineering and suffocating mother, but neither did she want to be independent and support herself. (If she ever had to do that, she said, she would kill herself.) She decided that she needed a husband to support her, and she began to look around.

In 1908, Sara had begun a correspondence with a poet in New York City, John O'Hara, which developed into a life-long friendship. However, Sara developed an infatuation with O'Hara that was fueled by her fantasies about him made possible by the fact that she had never met him face-to-face. Indeed, she was scared by the prospect of real love and avoided meeting O'Hara on several occasions. She eventually met him in the January of 1911 and realized that he was not suitable as a partner for her.

In 1911, Sara persuaded her parents to let her go to New York (at age 27, she still needed their permission), and she began visiting New York for meetings of the Poetry Society, building up close relationships with writers there. When away from New York, she kept in touch with friends there by letter. Interestingly, when she was in New York, Sara showed little of the exhaustion and illness that plagued her in St Louis.

In the summer of 1912, Sara and Jessie Rittenhouse took a trip to Europe, and on the boat back Sara met Stafford Hatfield, an Englishman, with whom she became infatuated. It is not

clear whether he wanted Sara to become his lover or return to England with him. But Sara could not cope with her anxiety, and she fled back to St. Louis. From afar, Hatfield no longer was as interested in Sara as he had once seemed, and eventually he ended the relationship. This episode persuaded Sara that she had to plan more purposefully to get married or else she would remain a spinster. Since erotic emotions frightened her, perhaps rationality could find her a husband?

The next romantic figure was John Wheelock, also a poet. But though Sara fell in love with him and gave him every opportunity to declare his love for her, he never did. In 1913, Sara began a correspondence with Vachel Lindsay, also a poet, and they finally met in 1914 in St. Louis. After this meeting, they wrote to each other more often, and eventually Vachel fell in love with her. However, in 1914 Sara was introduced to Ernst Filsinger, who was running a shoe business in St. Louis. He too was attracted to Sara, and soon Sara had to choose which one to marry. John Wheeler was still the man she loved, she thought, but he did not want her. So she had to choose from two men, neither of whom she loved, but both whom seemed to love her.

In 1914, Sara's father had suffered a stroke and her mother's health was also poor. These events happened at a critical point for Sara. The poor health of her parents made the question of what would happen to her once they died more urgent. Vachel was poor, too full of energy and too egocentric to be a caring husband for Sara. Ernst appeared to fit the role much better. Their interests and natures seemed harmonious, and he appeared to worship her. He would make a good husband and father for her children. Despite Sara's misgivings, which she did not tell anyone till many years later, they married in December 1914 in St. Louis.

The marriage was a disaster from the beginning. Sara could not abide sleeping in the same bed with a man, and so they always had separate bedrooms, at home, in hotels, and even on board boats. Sex too, apparently, was a disaster. Sara developed a bladder problem that caused excruciating pain soon after the wedding which lasted for two years and probably limited their sexual relationship. More importantly, Sara never felt passion for Ernst.

Life must have been difficult for Sara at this point. She had chosen the conventional life of marriage partly to get away from her parents, partly for security, and partly because she was a conventional person who expected to live conventionally. But since love was missing, and passion too, she had failed. She was faced with a difficult interpersonal relationship, an absence of love, and probable future unhappiness. Sara had one solution open to her. She retreated into illness again.

Sara and Ernst made their home first in St. Louis and then in New York City, and they chose to live in hotel apartments to spare Sara the strain of running a house and staff. Ernst was proud of Sara's poetic talent and encouraged her in every way he could. Her third book of poems appeared in 1915 from Macmillan, again receiving excellent reviews. And her next book of poems in 1918 received a prize that was the forerunner of the Pulitzer Prize.

Married life soon developed a clear pattern. Sara continued to write poems and edit collections. Ernst became involved in international trade and was called upon to travel the world widely, but at a pace that would strain Sara too much. So she stayed in New York and took trips to secluded spots around

America. Sara continued to feel frail, so that even socializing was restricted. She would send Ernst in her place occasionally to read her poems and to important meetings, and even to social events with her friends for company. Ernst screened her mail when she was away and occasionally handled her business affairs. Sara even turned down honors because they would involve evening dinners or travel.

Very soon a conflict developed in their relationship. Ernst's new job, after his shoe business went bankrupt, was in international trade. He became an expert on the topic. He gave talks all over America and traveled all over the world. Sara encouraged him in this, since she wanted him to be successful and she also wanted financial security. But she also resented the fact that he threw himself so energetically into his work (which he may have done in order to cope with the frustrations arising from his marriage). She was continually telling him to take it easy.

Then again, she missed him a lot at first when he began to travel although, after he came back, she seemed unable to cope with him in their apartment. She would become depressed, fall ill and go to her hospital in Connecticut or to a favorite vacation spot. In fact she seemed most content by herself in hospital or resort hotel as long as Ernst stayed in New York City.

However, much as she found life with Ernst difficult, at least his presence kept her depression at bay and took her mind off self-destructive thoughts. Ernst's absences brought Sara closest to feelings of love for him.

Surprisingly, in 1917 Sara became pregnant. Although she had thought she wanted to be a mother, the reality of it now threatened to interfere with her career. More importantly, it threatened her role as a patient. How could Sara cope with taking care of someone else? So she had an abortion. Of course, she could justify an abortion on the grounds of her frail health, but she possibly felt some guilt over her decision. (It is not clear whether Ernst knew of this.)

For much of their life, their financial position was not secure. Though they could afford a comfortable life style, especially supplemented by Sara's earnings from her writings, in early years they had to borrow from Ernst's family to get by. Sara considered ways of increasing her contribution to their income, but she never did much about it.

The absences caused by Ernst's traveling grew. In 1920 and 1921, they were together just six weeks in a period of a year and a half. Sarcasm grew more common between them, they brought up old annoyances, and they readily got hurt over new trifles. Ernst grew more defensive, moody and irritable, and his explosive temper showed itself more.

The Divorce and Final Years

Sara's decision to divorce Ernst in 1929 came as a surprise to her friends. Sara feared abandonment, and this fear had been made worse by his frequent absences. Eventually she began to fear that he would be attracted to another woman. This was possible, of course, since she would not be his lover and since he was away a lot. However, there is no evidence that Ernst ever behaved in any way as to reinforce these fears.

She had discussed divorce with Ernst before, but he had protested. So she planned the divorce in Nevada while he was away. She divorced him for mental cruelty and begged him not to contest it. Although she expressed euphoria at being free,

when she was back in New York, she soon sank into a depression. After the divorce, Sara lived in hotel apartments by herself, just as her marriage had consisted of living in hotel apartments mainly by herself while Ernst was away. Her life changed little, except that Ernst no longer made occasional visits!

Sara met a young student, Margaret Conklin, who became her close friend in her final years. Margaret would visit daily, and they went to Europe together. However, interestingly, Sara showed little concern for Margaret. She ate meals sent up to her from the hotel in front of Margaret without ever worrying whether Margaret had eaten. Sara had been in the patient role all of her life, with others taking care of her, so that she had never learned that sometimes one has to take care of others. If Margaret upset Sara in some trivial way, she would even be banished for days at a time.

Sara grew more inflexible. She still gave friends specific appointment times for their visits, and now she kept them waiting if they arrived a few minutes early. These latter years illustrated quite clearly her egocentricity, her lack of caring for others, and her selfishness.

In the final years of her marriage, Sara had experienced periods during which she could not write. She went from the summer of 1920 till November without writing one poem. These long barren spells became quite common – five months in 1925 and more during the period leading up to her divorce. But even after the divorce, writing was not easy.

Sara had experienced depressions throughout her life. In later years she lost weight. She suffered from insomnia, although during her creative periods she would work on her poems during the night, and she also had trouble getting up in the mornings, typical symptoms of depression. She took Veronal as a sleeping tablet. Her moods varied with the seasons. Her depressions were worse in winter, and she hated the cold weather since it brought on her respiratory illnesses. As she grew older, external events led to an intensification of her depression (such as the marital problems of her friends, the Untermyers, and the suicide of their son).

Sara's father died in 1921 at the age of 82, and this was a severe loss for Sara. Her mother died in 1924, as did her older brother George. In 1928, a friend, Marguerite Wilkinson, drowned after recovering from a nervous breakdown. Later that year, Sara was injured in a taxicab accident. In September of the year, Ernst's father died.

Sara's concerns over her finances grew. After her parents' death, the inheritance was not as great as had been expected. The stock market crash in 1929 also increased her anxiety. After the divorce, although she had asked for no alimony, Sara tried to get Ernst to set up a trust fund for her. She worried whether she could afford to renew the lease in her hotel and decided to move to a cheaper apartment. Her concerns became almost a nightmarish obsession. However, she left almost 84 000 dollars, and so it appears that her financial concerns were irrational.

After her divorce in 1929, many of Sara's friends moved away from New York City, and she was often lonely. Despite craving company, she often rejected offers from friends to visit her, pleading illness. In 1931 Vachel Lindsay killed himself by drinking Lysol, and Sara was distraught over this. For many months after Lindsay's suicide, Sara feared that she was about to have a complete physical breakdown or die in an accident.

Sara was no longer able to write productively, but John Wheelock suggested she write a biography of Christina Rossetti. Macmillan gave her an advance on the project, and she had written about a hundred pages at the time of her death.

In August 1932, Sara went to England to gather material for the biography but got pneumonia. She came back to America in September 1932, still sick, and recovery was slow. She was very weak and deeply depressed. She had failed to build a fruitful life after the divorce, and now only ill health seem to lay ahead for her. She worried that her heart had weakened and that her blood pressure was fluctuating too much. Her friends were very concerned over her despondency. She was taking sleeping pills regularly and seemed severely depressed.

During the Fall, the deaths of some friends deepened her despondency, and in December she began to accumulate a supply of sleeping pills. She began to fear having a stroke, like her father and her brother John (who had lived for 20 years after a paralytic stroke, dying in 1917 at the age of 47).

In December, she went to Florida to stay with Jessie Rittenhouse but lay in bed all day with the drapes closed. Jessie discussed the situation with Sara's doctor and nurse, and they all felt she should return to New York and seek psychiatric help. She developed an obsessive but unfounded fear that her blood vessels were beginning to rupture, increasing her fear of a stroke. On 27 January 1933, a blood vessel did break in her hand, making her frantic with the idea that her long-awaited stroke was imminent.

On the evening of 29 January 1933, Margaret Conklin visited her. They read and listened to Beethoven's *Fifth Symphony*. Sara was found the next morning at 9 a.m. by her nurse, dead in her bath after taking an overdose of sedatives. The water was still warm, and perhaps the nurse could have saved her had she checked earlier.

Sara Teasdale's Poetry

Sara was a lyrical poet and, at the time (the early part of the twentieth century), her poetry was popular. Sara was awarded the Columbia Poetry Society Prize in 1918, the forerunner of the Pulitzer Prize. Her poetry has been praised for its verbal precision and its exploration of human emotions (www.enotes.com), but it later fell into obscurity and was criticized for being sentimental and anachronistic and for being pure lyricism (www.enotes.com).

Discussion

In 1979, Drake pointed out that four major women poets of the nineteenth century (Emily Bronte, Christina Rossetti, Emily Dickinson, and Elizabeth Barrett Browning until she was 40) were all recluses like Sara. All four belonged to very close family units which fulfilled their desires for affection and intellectual stimulation. Sara ventured out more than some of her predecessors but continually retreated into seclusion because of her 'illnesses,' becoming almost a total recluse by the end of her life.

The Victorian era encouraged women in the creative arts but undermined their self-confidence. They were allowed to

dabble, but they were not supposed to achieve. When they did write poetry, they wrote mostly about love, protective love, and the desire to submit to the ideal lover. However, it was not always easy to find this in their own lives. They often ended up renouncing love for men and substituting an attraction to death, and these themes are frequent in Sara's poems. They frequently had mysterious physical weaknesses and chronic ill health, a neurotic way of resolving the conflict between their personal desires and the conventions imposed upon them by the society.

Sara was a chronically depressed woman whose depression worsened as she grew older. In her middle age, concerns that were mild as a young adult grew to be irrational obsessions. She feared poverty and an imminent death, though neither was very likely. It is unfortunate that Sara would contract a real illness (pneumonia) at this time and that a blood vessel did break in her hand. Her irrational concerns no longer seemed so irrational to her.

She had struggled to lead a conventional life but failed. Sara never learned to form and maintain healthy interpersonal relationships. The patient role she learned as a child was of no use to her in marriage. Simply put, she failed to mature. She remained a child, as evidenced by her failed marriage and the self-centeredness she displayed in her friendships.

Her childhood experiences led her to repress her basic emotions. Anger, curiosity of the world, and sexuality were all suppressed by her aged parents, and in particular by her mother. She married at 30 with no realistic idea of the responsibilities of a person involved in adult relationships.

The prospect of having a child frightened her so much that she had an abortion. In looking for an event that could have turned her life around, this might have been it. The easiest change for a person to make in life is to switch to a role that is complementary to one that she has already had. Perhaps Sara could have become the nurse (mother) taking care of the patient (her baby) after her years of experience as the patient? But maybe not. Anyway, Sara panicked and avoided the experience.

By the end of her life, she was finding it hard to write creatively, she was lonely and isolated, and her irrational fears and depressions were getting worse. Sara had often contemplated death, and now she planned it. She had long used sleeping pills and knew the peace they brought her. And so she

sought the ultimate peace, not in bed, but in a warm bath, as if seeking the womb from which she may have wished that she had never emerged.

Sara does not seem to have suffered from a bipolar affective disorder (manic-depression) or a major depressive disorder, nor did she abuse alcohol, the two classic accompaniments of creativity. Rather Sara seems to have developed a chronic maladaptive life style, technically known as a personality disorder, perhaps as a result of the way her aged parents raised her. Certainly she was depressed from time to time, but melancholia is a frequent human experience and does not always indicate a psychiatric syndrome.

Did Sara write better when she was depressed? She herself felt that her poetry was stimulated by her 'emotional irritation' and that this irritation was present long before she was conscious of what was tormenting her. In an interview in 1919, she said that her poetry sprang from a 'fog of emotional restlessness.' It is not clear exactly what emotions she was referring to, and it is not possible to match the poems to her psychological state at the time to see whether her poems were better when she was 'irritated' or 'restless.'

Glossary

Conceptual definition The definition of an abstract construct using other abstract constructs.

Convergent thinking Cognitive processes that result in one or a few responses to a question or stimulus.

Divergent thinking Cognitive processes that result in numerous ideas in response to a question or stimulus.

Histriometrics The application of quantitative analysis to data concerning historical figures.

Operational definition The definition of an abstract construct in observable, measureable terms.

Psychometrics The quantitative analysis of psychological measurement characteristics.

Reliability The extent to which test scores show consistency.

Validity The extent to which inferences drawn from test scores are appropriate for their use.

Why Assess Creativity?

Creativity is a fundamental human characteristic. We recognize evidence of creativity across time and across cultures, from ancient civilizations to twenty-first century endeavors. We see it displayed at the individual level as well as in collaborative enterprises, and we see its effects in small ideas as well as in revolutionary advances. Creativity's contributions to all areas of human activity, including science and technology, medicine, government, agriculture, literature, the arts, and entertainment are undeniable. There is no doubt that creativity enriches and enhances our lives.

Because of the breadth and depth of its impact, understanding and capturing creativity is of great interest. In order to systematically study creativity, however, one must have a means of assessing it. Assessment simply refers to the evaluation of the quality or quantity of a construct. Assessment may be based on one or more measures, or methods of measuring, or quantifying, the construct. Testing, a special case of measurement, refers to the use of standardized procedures for quantification of a construct.

Numerous techniques of varied types have been developed to assess creativity in individuals, groups, and organizations. Creativity measures are generally used to identify creative potential, to examine and understand factors that relate to creative performance, or to determine the impact of creativity interventions. The popularity and diversity of creativity assessment techniques illustrates our desire to grasp the valuable resource that is creativity.

Is Creativity Assessment Possible?

Creativity is a broadly used term. Sometimes, it is used to specify a personal characteristic, such as when we describe an individual as having high levels of creativity. On other occasions, we use it as a descriptor of objects or ideas, as is the case when we offer opinions about the level of creativity displayed in artwork. Yet in other applications it refers to a cognitive process, such as when a person is encouraged to use creativity in developing a solution to a problem. Although the term has

varied applications, there is a shared sense of its general meaning: creativity involves producing something new and different, something that did not exist previously.

The meaning of creativity evokes skepticism about the possibility of assessing it. How can we measure something that is unknown? Is it possible to understand an outcome that is unforeseeable? Can we capture the seemingly elusive construct that is creativity? Although the assessment of creativity may seem paradoxical, it is not. In assessing creativity, the goal is not to predict specific creative outcomes, but rather to measure characteristics related to creative production irrespective of specific outcomes.

Considered in this light, assessment of creativity is feasible and, given the importance of creativity for individuals, society, and culture, it is critical to understanding human nature.

Defining the Construct

As with any abstract construct, a definition must first be established in order for assessment to take place. Most researchers in the field identify creativity as an ability to produce objects or ideas that are novel and purposeful.

According to this perspective, creativity involves two components: novelty and appropriateness or usefulness. The first component is widely accepted. Most people identify creativity with originality. The second component, however, is more controversial. Why must something be appropriate or useful in order to be considered creative? Is it not the case that many creative works were deemed highly inappropriate by society at the time of inception? Creativity scholars interpret 'appropriateness' and 'usefulness' in the broadest sense. The original idea should have intent, purpose, meaning, in order to be creative. A unique random thought produced by an individual is generally not considered creative unless it is developed or applied with some intent or purpose. The nature of this intent may vary widely. It may consist of solving a practical problem or developing a coherent theoretical model. But it may also consist of expressing an emotional state for oneself or for others, in provoking an emotional reaction, or in presenting an alternative perspective or method. A dream you have may

be very unique, so much so that you share it with friends and family who proceed to describe it as 'really weird' or 'bizarre,' yet we do not generally describe that dream as demonstrating creativity. Implementing ideas that are gathered from your dreams, however, may be associated with creativity.

This definition of creativity remains conceptual and vague. It lacks precision that allows one to pinpoint exactly what or who demonstrates creativity. According to the definition, creativity is context dependent. To identify something as original, one must establish a point of comparison. Is it original in relation to the entire history of humanity? Is it original in comparison to the typical work produced by members of a certain age group within a specific culture? Or is it original within one person, a new idea for a particular individual? To determine appropriateness, one must also consider context. Is the idea or artifact appropriate given the situation in which it was produced? Would creative works from past centuries be considered equally provocative or ingenious if they had been produced for the first time today? A creative response is a response within a socio-cultural context.

The conceptual definition of creativity must be operationalized, or expressed in observable terms, in order to develop creativity assessment techniques. Both the purpose of assessment and the theoretical perspective of the researcher affect how a construct is operationalized. Assessing creative potential in children, for example, requires a different measurement approach than evaluating the creative contributions of eminent historical figures. Because of the multitude of purposes for which creativity assessment might be used, a wide array of measurement techniques have been developed.

Historical Foundations

Until relatively recently, creativity was not scientifically studied. Explanations of creative outcomes, if given at all, frequently referred to supernatural influences such as muses, divine intervention and demonic powers, or to vaguely identified personal characteristics such as 'giftedness' and 'madness.' Many believed these external or internal forces in turn produced an 'a-ha' experience in individuals that in turn propelled them to act on their ideas.

As the study of individual differences in psychological characteristics gained importance in the late 1800s and early 1900s, greater attention was directed toward the construct of creativity. Initial steps toward assessing creativity began with experimental attempts to measure fluency and imagination. Stimuli such as inkblots or word association tasks were used to assess these constructs. At this time, investigators considered creativity to be either a component of general intellectual functioning or a characteristic of personality.

J. P. Guilford is credited with directing greater attention to the scientific study of creativity and providing a framework in which to do it. In 1950, his presidential address to the American Psychological Association emphasized the need for psychologists to dedicate more time and effort to understanding creativity. He developed a multidimensional model of intellect, called the structure of the intellect (SOI), that classified mental abilities by operation performed, content used to perform the operation, and the type of product produced.

The broadest impact of this model was the distinction between two types of operations, convergent thinking, associated with traditional forms of intelligence, and divergent thinking, associated with creativity. Convergent thinking refers to a mental process that focuses an individual on one correct response. Divergent thinking, in contrast, is a mental process that results in a wide range of potential responses. Guilford and his colleagues identified several primary components of divergent thinking. These included fluency, flexibility, elaboration, and originality. Fluency is the number of interpretable ideas produced in response to a stimulus. Flexibility refers to the number of different categories of ideas produced. Elaboration is the embellishment of ideas. Originality is the uniqueness of the ideas. Guilford and his associates also designed measures to assess the components of divergent thinking.

Although the concept of divergent thinking did not originate from Guilford, he was instrumental in popularizing both the construct and means of measuring it. Guilford believed divergent thinking was a distinguishing feature of creativity, and most current theories of creativity consider divergent thinking to be a necessary, although not sufficient, requirement for creativity. Furthermore, Guilford's conceptualization of divergent thinking influenced the development of a popular method of assessing creativity, divergent thinking tests. The divergent thinking tests developed by Paul Torrance shortly after Guilford's presidential address continue to be some of the most widely used creativity tests worldwide.

Guilford's call for more research on creativity not only impacted the study of creativity as a mental ability. His work also stimulated researchers to study creativity as it relates to personality. Of particular importance was the work conducted by researchers at the Institute of Personality Assessment and Research at the University of California in Berkeley. Both Frank Barron and Donald MacKinnon are noted for providing important insights into the characteristics of creative achievers. Their research influenced the use of personality measures as well as ratings of creative achievements for the assessment of creativity.

Since the mid twentieth century, researchers have made significant strides in the study of creativity. Numerous useful measures of creativity have been developed as a result of this research that serve, in turn, as tools for furthering our understanding of creativity. More research in this area, however, is warranted. Although great progress has been made, the scientific study of creativity remains limited relative to the importance of this construct.

Focus of Creativity Assessment

Because creativity is a broadly applied construct consisting of complex processes, development of creativity assessment approaches requires that a point of focus be identified. This point of focus involves both facets of creativity and types of creativity.

Facets of creativity have been grouped into four broad categories: products, people, processes, and environmental press. These categories are commonly referred to as the 4Ps of creativity. Most studies oriented toward understanding creativity examine how people, processes or environmental

conditions contribute to creative outcomes. Each of these categories necessitates that assessment efforts have a different focus. In measuring products, the emphasis is on specifying the level of creativity displayed in objects or ideas. In order to do so, type of product should be considered. Inventions, for example, may best be assessed using different methods than those applied to the evaluation of artwork. In assessing creative people, the interest is in identifying attributes associated with creative individuals. In this case, consideration must be given to the population of interest. Methods for evaluating creativity in children may differ from those for adults. In assessing processes, the researcher focuses on the cognitive functions involved during the varied stages of creativity. With environmental press, the interest is in determining the environmental conditions that, when pressed upon a person, enhance or inhibit creativity. Measures of creativity may be described in terms of the 4Ps that they emphasize.

Creativity assessment procedures must also adapt to the different types of creativity that exist. A distinction is made between eminent creativity and everyday creativity. Eminent creativity, referred to as 'big-C,' is that displayed by individuals of renowned fame who are recognized as creative geniuses. Figures such as Einstein, Beethoven, Cezanne, and Galileo, represent eminent creativity. In contrast, everyday creativity, referred to as 'little-c,' is displayed in creative endeavors that have less breadth or depth of impact on society. Everyday creativity may present itself at a personal level, in original and useful responses within the range of responses typical for a particular individual, or at a social level, in original and useful responses relative to those produced within a socio-cultural group. It may consist of the development of completely new ideas or the adaptation of existing objects to meet new demands. Examples of everyday creativity include original artwork produced by children, unique dance moves that become the popular trend, or small adaptations of objects to meet current demands.

These two types of creativity, big-C and little-c, are studied using different methods. Eminent creativity is most commonly examined through case studies or historiometrics. Case studies generally produce qualitative descriptions of individuals, while historiometrics involves the quantification of information related to historical figures. Eminent creativity is interpreted as representing the highest level of achievable creative performance. It can serve as a standard to which all other creativity is compared. Its study, however, is limited by what information is available in historical records and how this information is used. The study of everyday creativity generally examines creativity of the present, which allows for the use of a broader array of assessment methods. It also relies on assessment of creativity in a relative rather than absolute fashion. In so doing, the creativity of a participant may be compared to that of others, or to one's own under different conditions, instead of to an absolute level of creativity. This relative approach to assessment acknowledges the importance of context for creativity.

The varied points of focus in creativity assessment give the sense that creativity researchers are very scattered in their study of creativity. At the same time, the availability of creativity assessment techniques that have varied points of focus provides an opportunity to examine creativity from different perspectives.

Types of Creativity Measures

Creativity measures can be classified into several types depending upon their aim and content. According to a popular taxonomy presented by Dennis Hocoavar and Patricia Bachelor, the primary types of creativity measures are: divergent thinking tests; attitude and interest inventories; biographical inventories; personality inventories; ratings by peers, teachers, or supervisors; ratings of eminence; judgments of products; and self-reported creative activities. A variation of this taxonomy with an added category, environmental climate inventories, is used below as a framework for discussing types of creativity tests.

Divergent Thinking Tests

Divergent thinking tests are arguably the most frequently used approach for assessing everyday creativity. These tests ask participants to produce multiple ideas in response to specific stimuli. Stimuli and responses are typically either pictorial or verbal in nature. Examples of item response formats include drawing pictures using an incomplete figure, writing questions evoked by hypothetical situations, or listing possible uses for an object. The intent is to measure divergent thinking skills displayed in test-taker responses. Divergent thinking tests usually assess multiple skills, and those most frequently assessed are fluency, flexibility, originality, and elaboration.

Many divergent thinking measures are available. Some of them are considered general tests that can be administered to a broad segment of the population. These include the *Torrance Tests of Creative Thinking (TTCT)*, the *Alternative Uses or Consequences* tests, and international instruments such as the Spanish *CREA* test. Other divergent thinking tests have been designed with stimuli that apply to specialized fields of expertise, as is the case with the *Purdue Creativity Test* for engineers and the *Creative Engineering Design Assessment (CEDA)*. Some measures assess both divergent and convergent thinking. The *Structure of the Intellect Learning Abilities Test (SOI-LA)* is an example of such an instrument designed for the general population.

Of the numerous divergent thinking tests available, the *Torrance Tests of Creative Thinking* are currently the most popular both in the United States and abroad. They are considered the gold standard of divergent thinking tests. Various Torrance Tests are available, including verbal (*Thinking Creatively with Words*), figural (*Thinking Creatively with Pictures*) and abbreviated measures (*Abbreviated Torrance Test for Adults, ATTA*). Each consists of several tasks that are scored on multiple dimensions. Subscores and overall scores are then computed.

Research on the Torrance tests and on divergent thinking tests in general indicates that they typically demonstrate positive psychometric characteristics. Overall scores have strong reliability although subscores frequently do not have sufficient reliability to warrant individual interpretation. Evidence supports the contention that divergent thinking tests measure a construct that is distinct from that measured by traditional academic aptitude tests. Validity studies show that overall scores are related to creativity as measured by expert evaluations of performance as well as by creative achievements. Studies examining the ability of divergent thinking tests to predict

creative performance in the long term demonstrate weaker associations than those examining associations between divergent thinking and creative performance in the present. Critics of the tests argue that their ability to predict future creative performance is limited.

A number of studies have found that scores on different types of divergent thinking tasks, such as verbal, figural, or mathematical, do not show strong associations with each other, suggesting that domain specific skills influence test performance. The basis for this finding may lie in the fact that divergent thinking tasks require additional skills beyond divergent thinking that are linked to domain expertise, rather than in the notion that the process of divergent thinking itself is domain specific. Regardless of the reason, it appears that divergent thinking tests containing different types of stimuli and response formats are not completely interchangeable.

Overall, despite some limitations, research on divergent thinking tests indicates that they can be useful in measuring an important component of creativity, divergent thinking.

Self-Assessment Inventories

Creativity self-assessment inventories focus on characteristics of the person rather than on an evaluation of thinking skills demonstrated in the production of a response. Their purpose is to tap into one's personal orientation toward creativity. There are several types of self-assessment inventories, including attitude and interest questionnaires, biographical inventories, and personality measures.

Attitude and interest inventories are based on the belief that creative individuals tend to have attitudes and interests that distinguish them from less creative individuals, such as positive inclinations toward taking risks, trying new activities, engaging in hobbies that allow exploration or self-expression, or being playful. Questions in these inventories may consist of rating scales, forced-choice options, or checklists. Examples of such inventories abound. The *Creative Attitude Survey* assesses characteristics such as imagination, creative interests, humor, and risk-taking in children. The *Group Inventory for Finding Interests (GIFFI)* examines interests associated with creativity in children. Appropriate questionnaires for adults are also available, such as the *How Do You Think?* And the *How Creative Are You?* The *Khatena-Torrance Creative Perception Inventory* has two subtests: *Something About Myself* focuses on interests and *What Kind of Person Are You?* assesses personality characteristics. The *Creative Styles Questionnaire-Revised* integrates elements of interest and personality into one measure in an effort to assess thinking style that relates to creativity.

Biographical inventories for creativity collect information on individuals' activities and experiences that are believed to be associated with creative performance. These inventories include questions on topics such as current and past hobbies, leisure activities, family history, childhood environment, and educational experiences. In addition to questions that are biographical in nature, these inventories sometimes include items related to interests and attitudes. The item format is usually a frequency rating scale or a checklist. Biographical inventories may be general or domain specific. *Biographical Inventory: Creativity* is a broadly focused inventory that incorporates dimensions specific to varied fields. Other inventories, based

on evidence of differences in the backgrounds of creative individuals from diverse fields, are designed to apply to specific areas of expertise. The *ALPHA Biographical Inventory* from the Institute for Behavioral Research in Creativity, for example, was designed for scientists.

Interest/attitude inventories and biographical questionnaires have strengths and weaknesses. They are relatively easy to administer, and research shows that they generally have adequate reliability. Studies comparing the two types of tests indicate that interest/attitude inventories and biographical inventories are highly interrelated. This is not surprising for several reasons. First, to the extent that individuals have choices about activities, interests can affect activities. Second, as stated earlier, biographical inventories may contain interest items, and interest inventories may contain biographical items, thus blurring the distinction between the measures. These inventories, however, provide distinct information from that obtained by divergent thinking tests as indicated by relatively low associations between scores on the two types of measures. Validity studies generally provide some support for the use of interests, attitudes, and biographical information in evaluating creative potential. Some specific inventories, however, provide limited evidence of validity. Further examination of the validity of these inventories is warranted.

Personality inventories assess an individual's typical pattern of responding to situations. The characteristics assessed may be defined as personality traits or types. Most personality inventories studied in relation to creativity are questionnaires that assess an array of personality dimensions, some of which are believed to related to creative performance. Examples of these inventories include Cattell's *16 Personality Factor Questionnaire (16PF)* and the *NEO Personality Inventory (NEO P-RI)*. The *Creative Personality Scale* from the *Adjective Check List* is an example of a creativity scale that was developed from a personality inventory. Other inventories are specifically designed to assess the creative personality, as is the case with the *Cree Questionnaire*.

Currently, the most commonly studied personality characteristics in relation to creative performance are the five *NEO PI-R* characteristics of extraversion, emotional stability, openness to experience, conscientiousness, and agreeableness, commonly referred to as the Big 5. Much research has been conducted on the relation between these characteristics and creativity.

Evidence is somewhat inconsistent, but patterns of relationships have emerged that suggest differences in personality characteristics associated with creativity in various domains. Openness to experience is the characteristic that is most consistently associated with creative performance. Extraversion has been found to relate positively to performance on divergent thinking tasks and in creative occupations that require social interaction. Conscientiousness appears to show a positive association with scientific creativity but not artistic creativity. Emotional instability, in contrast, has been found to be positively associated with artistic creativity. The Big 5 dimensions are very broadly defined, which limits the ability to specify aspects of personality that relate to creativity with precision. Subcomponents of the *NEO PI-R* measures as well as alternative measures, such as the dimensions of the *16PF*, have been used to examine the relationship of more narrowly defined personality

characteristics to creativity. The *16PF* characteristics of persistent, adventurous, imaginative, shrewd, and self-sufficient have been related to creativity. Continued research should clarify how personality characteristics interact with domains of creative pursuit.

Self-Reported Creative Activities

Self-reported assessments of creative activities are similar to biographical inventories in that they focus on past activities and accomplishments. They are distinct in that they aim to specify the quantity and/or quality of creative activities, rather than personal experiences that are associated with creative performance. In other words, the focus is on the product rather than the person.

These assessments usually produce counts of real-life accomplishments believed to show evidence of creativity, or ratings of frequency of involvement in creative behaviors. In some applications, the accomplishments may be ranked or rated by quality. Writing plays, stories or musical pieces; publishing research articles; being selected for art show participation, receiving special awards and recognitions for original contributions; and obtaining patents for inventions are all examples of creative accomplishments. Some inventories for assessing creative activities are the *Creative Activities Checklist*, the *Creative Behavior Inventory*, and the *Creative Achievement Questionnaire (CAQ)*. Another inventory, the *Runco Ideational Behavior Scale (RIBS)*, assesses self-rated level of engagement in ideational activity rather than actual creative accomplishments. As such, it shares similarities with questionnaires intended to assess thinking style. Further research on this inventory to examine its relation to other types of measures is warranted.

Self-reported creative activity measures are valuable as criteria, or standards, to which other creativity assessment instruments are compared. For example, research showing that divergent thinking tests are able to predict significant creative accomplishments provides validity for the use of divergent thinking tests as indicators of creative potential. Creative activity measures show strong reliability in overall scores. Difficulties in their use derive from the fact that substantial creative accomplishments are limited in number for most people, making it difficult to determine distinctions in creativity, while involvement in activities may relate more strongly to interests than accomplishments.

Ratings/Rankings/Nominations of People

In this form of assessment, a knowledgeable individual reports on other people's creativity. In the case of eminent creativity, the evaluator is usually considered an expert in a specialized field and is asked to either nominate individuals within that field whom they consider to have made important creative contributions, or alternatively to rate or rank the creative contributions of individuals in a provided list. In the case of everyday creativity, the evaluator is most typically a peer, teacher, or supervisor who knows the person well. This evaluator may be asked to provide a global rating of an individual's creativity or to rate the person on several dimensions related to creativity. The *Meecker Creativity Rating Scale* and the *Teachers' Evaluation of Students' Creativity (TESC)* were developed to rate

students on creativity-related characteristics, while the *Parental Evaluation of Children's Creativity (PECC)* asks parents to assess their children's idea generation. Teacher, peer and supervisor ratings, rankings and nominations have been used as criteria for evaluating the validity of creativity tests and the effectiveness of creativity interventions. Research shows that multiple evaluators with knowledge of an individual and information on the rating criteria provide similar creativity ratings. Some critics, however, question the level of validity of these assessments.

Judgments of Products

An alternative approach to rating people is to rate creative products. In this assessment approach, knowledgeable individuals rate ideas or artifacts on their level of creativity. One or several questions may be used in the rating scale. The most popular and sound method for rating creative outcomes is the *Consensual Assessment Technique*. In this method, multiple expert judges rate the creativity of an observable response within a particular domain. Artists rate paintings or collages, writers rate stories, mathematicians rate math problems, and so on. The average rating across experts is then used as the measure of creativity. Experts are also asked to rate other dimensions of the product such as technical quality or attractiveness to ensure discrimination between dimensions. Research shows that this method generally results in high agreement among raters on creativity and clear distinction of creativity ratings from ratings on alternate dimensions. The consensual technique, with its use of multiple raters, reduces error due to idiosyncrasies of raters. Judgments of products using the consensual assessment method have been used effectively as criteria in many creativity studies.

Creative Climate Inventories

A relatively recent approach in creativity assessment is to examine the extent to which the environmental climate supports creativity. Several measures have emerged which assess factors in the environment that may promote or inhibit creative performance. The purpose of the *KEYS: Assessing Climate for Creativity* instrument is to assess stimulants and obstacles to creativity in work environments. Questions in the instrument ask employees to rate their work environment on a number of dimensions believed to relate to creative production. The instrument can be used by employees at various levels in the organization, and scores show strong evidence of association with ratings of organizational creativity. The *Team Climate Inventory (TCI)* is intended to assess climate for innovation in work teams. The instrument measures four dimensions of team performance: vision, participative safety, task orientation, and support for innovation. Research to date indicates that these dimensions are related to perceived team performance on creative projects. These measures are an important contribution to the assessment of creativity (see [Table 1](#)).

Challenges and Opportunities

The various approaches to creativity assessment are quite distinct. Associations between scores on the diverse types of

Table 1 Partial list of creativity measures

<i>Name of test</i>	<i>Authors/date</i>	<i>Type of test</i>
16 Personality Factor Questionnaire (16PF)	Cattell, R. B. (1993)	Personality
Abbreviated Torrance Test for Adults (ATTA)	Goff, K. and Torrance, E. P. (2002)	Divergent Thinking
Adjective Checklist: Creative Personality Scale	Gough, H. and Heilbrun, A. (1965)	Personality
ALPHA Biographical Inventory	Institute for Behavioral Research in Creativity (1972)	Biographical
Alternative Uses	Christensen, P. R., Guilford, J. P., Merrifield, P. R., and Wilson, R. C. (1960)	Divergent Thinking
Biographical Inventory: Creativity	Schaefer, C. E. (1970)	Biographical
Consensual Assessment Technique	Amabile, T. (1982)	Judgment of Products
Consequences	Christensen, R. R., Merrifield, P. R., and Guilford, J. P. (1958)	Divergent Thinking
CREA	Corbalán, F. J., Martínez, F., Donolo, D., Alonso, C., Tejerina, M., and Limiñana, R. M. (2003)	Divergent Thinking
Creative Achievement Questionnaire (CAQ)	Carson, S., Peterson, J. B., and Higgins, D. M. (2005)	Activities/Accomplishments
Creative Activities Checklist	Runco, M. A. (1983)	Activities/Accomplishments
Creative Attitude Survey	Schaefer, C. E. and Bridges, C. I. (1970)	Interest/Attitude
Creative Behavior Inventory	Hocevar, D. (1979)	Activities/Accomplishments

How Creative Are You?	Raudsepp, E. (1979)	Interest/Attitude
How Do You Think?	Davis, G. (1975)	Interest/Attitude
KEYS: Assessing Climate for Creativity	Amabile, T. M., Conti, R., Coon, H., Lazenby, J., and Herron, M. (1996)	Creative Climate
Khatena–Torrance Creative Perception Inventory	Khatena, J. and Torrence, E. P. (1998)	Interest/Attitude/Personality
Meeker Creativity Rating Scale	Meeker, M. (1987)	Ratings/Rankings/Nominations
NEO Personality Inventory (NEO PI-R)	Costa, P. T. and McCrae, R. R. (1992)	Personality
Parental Evaluation of Children's Creativity (PECC)	Runco, M. A. (1989)	Ratings/Rankings/Nominations
Purdue Creativity Test	Lawshe, C. H. and Harris, D. H. (1957)	Divergent Thinking
Runco Ideational Behavior Scale (RIBS)	Runco, M. A., Plucker, J. A., and Lim, W. (2001)	Activities/Accomplishments
Structure of the Intellect Learning Abilities Test (SOI-LA)	Meeker, M. and Meeker, R. (1975)	Divergent Thinking
Teachers' Evaluation of Students' Creativity (TESC)	Runco, M. A. (1987)	Ratings/Rankings/Nominations
Team Climate Inventory (TCI)	Anderson, N. and West, M. A. (1996)	Creative Climate
Torrance Test of Creative Thinking: Figural (TTCT-Figural)	Torrance, E. P. (1966)	Divergent Thinking
Torrance Test of Creative Thinking: Verbal (TTCT-Verbal)	Torrance, E. P. (1966)	Divergent Thinking

measures indicate that they are not assessing identical constructs. This poses challenges in the study of creativity.

First, choices need to be made in terms of appropriateness of measures for the intended purposes of assessment. Using an instrument for predicting creative potential is quite different from using a measure to evaluate current levels of creative performance. A set of guidelines to assist creativity measurement users in the selection of instruments appropriate for their purposes would be quite practical.

Second, confusion can arise regarding what different assessment techniques actually measure. There is a tendency for the

interpretation of the meaning of test scores to extend beyond their actual meaning. Divergent thinking, for example, is frequently equated with creativity when it more accurately represents just one component of creativity, ideation. Creativity interest inventories may be interpreted as instruments for identifying creative people when they assess relatively limited aspects of individuals that may relate to increased likelihood of creative performance. In either of these examples, additional conditions must exist for creativity to be displayed. The confusion about the meaning of scores can lead to erroneous inferences being drawn from research results.

Third, the identification of appropriate criteria for the study of creativity is difficult. Frequently used criteria include performance on divergent thinking tests, ratings of creative products, or scores on creative achievement and activity measures. Divergent thinking test scores are a popular choice as criteria in research studies because of their availability, applicability to diverse populations, and strong psychometric characteristics. However, because the ideation displayed in these tests is produced within a testing condition that generally does not incorporate situational or motivational variables that affect creativity, performance on these tests does not mimic creative performance in real life. Their usefulness as criteria in certain studies, therefore, is limited. Other potential criteria, such as ratings of creative products or counts of creative achievements pose their own problems. Obtaining meaningful ratings of creative products with high psychometric quality can be difficult and time consuming. Furthermore, the products that are rated may not be representative of one's creative capabilities across time and across domains. Similarly, measures of creative achievements may not be representative in that achievements might not be fully realized at the time of assessment. Using multiple criteria can compensate for limitations in any one assessment approach, and is therefore highly valued in research studies.

While challenges exist, the various approaches for assessing creativity also provide opportunities for integration of the creativity literature. Research studies in creativity tend to examine one or a few factors at a time using one or a few methods of assessment. Current models of creativity, in contrast, theorize that multiple components must be present for creativity to emerge. Several confluence models exist, such as those developed by Teresa Amabile and by Robert Sternberg and Todd Lubart. Although there is some variability in the components specified by each of the models, they share basic elements. These include creative thinking skills, personal characteristics, and environmental factors that promote creativity. The tendency to study factors that influence these components individually prohibits a full understanding of the creative process. There may be very complex interrelationships between the various factors involved in creativity and the diverse types of creativity. For this reason, studying one factor at a time using one measure of creativity may be misleading. Research using different types of creativity measures to assess the multiple aspects of creativity can illuminate the interrelationships between components of creativity. The variety of creativity measures that exists, therefore, is an important toolbox that can be used for integrating research findings into a coherent theoretical framework.

Glossary

Brahma In Hinduism, the creator, the first member of the Trimurti, with Vishnu, the preserver and Shiva, the destroyer.

Commedia Dell'arte Italian, meaning literally comedy of the artists (or guilds) is a form of improvised theater encompassing a set group of characters played in masks that began in Italy in the sixteenth century and is still performed today.

Culture The behaviors and beliefs characteristic of a particular social, ethnic, or age group. According to anthropological theory, culture is the sum total of ways of living built up by a group and transmitted from one generation to another.

Hellenistic theater A name given to ancient Greek theater. It refers to the age of the Persian Empire, ruled by Alexander the Great, and commonly known as the Hellenistic Period.

Kabuki Popular drama of Japan developed in the seventeenth century and characterized by elaborate costuming with a stylized acting style comprised of rhythmic dialogue, music and dance; men playing both male and female roles.

Noh theater Traditional Japanese theater and one of the oldest theatrical forms in the world. Name derived from Japanese meaning talent or skill. Performers are storytellers and rely less on plot than visual imagery.

Passion plays A religious drama concerning the crucifixion of Christ widely performed on Good Friday in the Middle Ages and still performed today by the villagers of Oberammergau, Bavaria.

Sanskrit An indo-European, Indic language in use since c. 1200 BCE as the religious and literary language of India.

Stage The area where the storytelling/performance takes place. In Greek and Roman theaters it was a platform across the diameter of the semicircular arena, in Medieval drama the stage was generally a temporary wooden platform with a trap door representing hell and a raised structure representing heaven. The thrust or apron stage appeared in the Elizabethan era with a permanent architectural background located in the back of the performing platform. In the mid-seventeenth century the proscenium stage was introduced with two areas, the fore stage or downstage area where most of the action took place and the area framed by an arched opening that contained scenic backgrounds with entrance areas located on either side at the back (upstage). By the mid-nineteenth century the picture-frame stage had virtually no forestage area; the entire playing area was located beyond the arched area. Site specific stages include exhibition halls, theater-in-the-round where the audience sat all around the performing area (a format frequently used by circuses). Today stages are as varied as the imagination of the directors, designers, and producers. Any area can become a performance venue, where performers and audience share theatrical events.

Yoruba Opera A Nigerian African entertainment patterned after English Musical Hall containing topical and satirical stories with dialogue, songs and dances. It began and ended with a rousing musical number called a Glee.

Introduction

Theater is a place designed and designated as a forum for the witnessing and sharing of stories of the culture for which the theater is built. It is a place where stories are given dimension and voice. The word theater comes from the Greek word *theatron* (the seeing place), and unlike *auditorium* (to hear), theater is the ultimate location to witness (see) that which the culture's performing artists regard as relevant, important or amusing. It has been, and continues to be, the place where we see archetypal themes embodied, where we see characters in full dimension struggling with the issues that are at the very heart of what is the human experience. Theater is always place, performer, and story.

The seminal director, Peter Brook, claimed that from the time when one Neanderthal acted out his prowess of a particularly good hunting expedition to others in the tribe, there was theater. He argued that theater must be clear and demystified; however, any live performance qualifies as dramatic by creating a representational illusion involving speech, gesture,

music, dance, spectacle, and/or combining other performing arts such as visual arts (i.e., installation art pieces, shadow theater). A myriad of venues house theatrical works including amphitheaters, Roman-style forums, Eastern Tea Houses, open-air sites, theater-in-the-round, black-box theaters, and theaters with thrust or proscenium stages. With technological advances in set design and lighting there is often a greater demarcation between audience and performer, yet both are inexorably linked through the experience of theater.

As a cultural institution, it is difficult to define theater through a single lens, as is evidenced by ongoing disagreements between artists and scholars regarding theater's ultimate form. Major journals and newspapers throughout the centuries have engaged in this debate on definition. Further, although distinctions are apparent in different geographical regions, theater practitioners tend to borrow ideas from other cultures, integrating and changing indigenous traditions and creating patterns of change that incorporate or reject traditional styles. Theater ultimately reflects and reveals its culture and the social/political policies of the times. Theater remains a dynamic

practice, whether it is used to promote aesthetic values, communal healing, or political propaganda.

Place, Performer, Story

Inevitably, the interaction of place, performer and story shapes the theatrical performance. It may be pleasing or disturbing, realistic or abstract, accurate or altered. Physical space affects individuals, especially when creativity takes place in a physical context such as within a theater. According to Tore Kristensen, in general, creativity takes place in confined spaces that restrict yet enable a free flow of sensory experiences and proximity to other people. The confinement may actually make certain sensory experiences more vibrant such as sight and sound, and frames cognitive processes while restricting others to induce emotional and creative responses. Such experiences, at their best, support coherence and continuity, optimal elements within creative works. This is what takes place within strong theatrical productions. Both performers and audience share in the constraints of the theater, even when performances are outdoors; it is the attention that is shared between performer and audience that contains the creative space.

Jerzy Limon argues that the space of the stage and the ways it is constructed are important meaning-generating elements within every theatrical production. The performance space, both real-world and artistic-construct, conveys metaphorical meaning. In the theater, the audience perceives space differently than in everyday life experiences (point of view can be altered and distorted) and they actively participate in conjuring things real and imagined. This is how Eastern theater most often functions. The audience can see the stage manager and stagehands, who appear on stage with the performers, yet the audience continues to attend to the story that is being portrayed. Further, designers are able to create sets that distort and enhance visual principles of perspective-taking, and different stages (thrust, in-the round, black-box, proscenium, site-specific) present unique limitations and opportunities for theatrical productions.

Although place, often the *mise-en-scene*, can set the location for theatrical productions, the relationship between the performer and the story remains tightly entwined and is, in many theatrical forms, the only tool to conjure place. This performer-story relationship often sparks much controversy since critics and audience alike may dispute the interpretation given by the performers on stage. Many argue that the text of a play can be analyzed as a literary work, independent of performance. In fact, there is substantial evidence that psychoanalytic theorists, most notably Sigmund Freud, furthered their psychological theories through the analysis of characters within dramatic texts. They claimed that the playwright's construction of plot and characters offered entry into the playwright's unconscious mind. According to Eric Neutzel, through careful analysis of plays such as Sophocles' *Oedipus Rex*, Shakespeare's *Hamlet*, or O'Neil's *Long Day's Journey into Night*, we can gain insight into the aesthetic values and responses of audiences and critics, the dark (shadow) side of human nature, the psychological struggles and defenses of writers and their characters, and the transferences, counter-transferences, and enactments manifested in the theatrical

processes that take place between actors and directors, actors and audiences, and actors and the characters they embody. Psychoanalytic textual and creative process analyses are compelling; however, according to Patrice Pavis, the text-performance 'couple' must be constantly reconsidered, especially since this relationship evokes questions about fidelity (whether the performance is true to the text). This is further complicated by the communal practice of theater-making. According to Nathan Kogan and Barbara Kangas, many directors and playwrights have previous acting experience, which adds more complexity to the text-performance relationship. In the end, what remains true in theater is the wedding of place, story, and performer.

Theater as Culture – Geographical Distinctions

As an artistic expression of the human condition, theater is influenced by and influences sociopolitical culture. Although it is impossible to give a full account of any one culture's theater history in this entry, the hope is to illustrate how major religious and political movements directly shaped the course of theater history. Like any dynamic social structure, theater reflects and responds to the forces of its time. Further, theater practitioners tend to adopt esthetic values from other cultures and integrate them into their own indigenous works, thus theater not only reflects local sociopolitical climates but also reveals the influences of remote cultures and times.

Western Theater

Western theater began in Ancient Greece (~500 BCE). Dance, music and drama (comedies, tragedies, and satyrs) were performed at major festivals. The ultimate goal of these ancient theatrical works was to promote harmony through the resolution of conflicting forces within the individual, society, and the gods. Following the guidelines later delineated by Aristotle, early Western theater portrayed stories that adhered to unity of place and time, in short, all Ancient Greek plays occurred in one setting during one 24-h period. According to Oscar Brockett, Greek theatrical practices incorporated the use of masks, singing, and dancing; they portrayed psychological realism while questioning social norms. One of the most significant theatrical developments during the Ancient Greek era was a shift in focus from choral performances to single actors who portrayed specific characters or gods. This practice began with Thespis, whose name is now applied to Western actors (Thespians). What is remarkable about Ancient Greek theater is that most of the conventions of Western theater started here. The power of Greek theater was in large part linked to the uncompromising integration of the poet and the performer; the storytelling was a perfect union of text and performer.

During the long reign of the Roman Empire, Greek theatrical principles were incorporated; however, more attention was given to elaborate spectacles. Bigger amphitheaters were built to house larger casts of performers and showcase spectacles that imitated real-life events. One of the major opponents to such theatrical presentations was the early Christian followers who banned all theater practices. This persisted well into the Middle Ages in Europe. Actors were denigrated by the church; however, they were granted permission to perform

elaborate Passion or Mystery plays during religious festivals. Small troupes of performers, traveling from village-to-village in wagons that served as both home and stage, provided theatrical morality plays that depicted either biblical stories or the plight of everyday man. *Every Man*, one of the most popular plays of this time, presented themes of human suffering and the triumph of good over evil.

During the Renaissance, church and state became more distinct and separate. As a result, theater was no longer restricted by the dictates of the Church as the performers and writers were given financial support from the courts. With this shift, a renewal of earlier Classical Roman aesthetics shaped Renaissance theater, including the focus on spectacle. Intermezzi were provided between the acts of the drama to feature dance and song, practices that later fostered ballet and opera as distinct art forms. Renaissance theater buildings were ornate indoor venues, and proscenium stages were invented to showcase elaborate stage scenery (sets). In Italy the *Commedia dell'arte* grew outside the influences of court spectacles. Like the earlier Greek theatrical tradition and influenced by Eastern theater practices, this form of theater focused on the skills of the performer. *Commedia dell'arte* proved to be a major historical influence on the development of future Western theater. Training performers in skills of improvisation, vocal range, and physical movement set the stage for playwrights such as Molière and the titan of all Western theater, William Shakespeare.

Shakespeare (1564–1616) was directly involved in Elizabethan theater, as actor, playwright, and part owner of the Globe and Blackfriars playhouses. He drew stories from history, mythology, fiction, and current events, reworking them into plays that were so distinct that they are now regarded as a form unto themselves. The universality of his work remains palpable today – his plays continue to be performed in every country of the world. Following the zenith of Shakespeare's Elizabethan theater, European theater fell under more government sanctions with fees and fines increasing the burden on burgeoning companies. Audiences, from royalty to peasants, demanded productions that appealed to all intellectual levels of understanding, thus more interludes and masques were produced within the dramatic productions. Scenic architecture evolved to meet audience demands and once again spectacles, much like those performed in Roman forums, became popular.

As the seventeenth century dawned, Europe was besieged by political and military conflicts. Theater responded to these changes with performances that were either more violent in presentation and content or diversionary and spectacular. With political instability, theaters promoted regional theatrical styles and views that reflected the rapid changes in the sociopolitical culture of Europe. Western theater in the eighteenth century gradually shifted from control by royalty, church, and government to individual businessmen. Restoration drama grew more sentimental, pantomime theater gained increased popularity, and opera and ballet companies completely separated from traditional theater productions. Nineteenth-century European theater shifted to more Romantic and melodramatic storytelling, and with this change came a new focus on the actor as the star attraction. This trend spread to the United States and Canada as well as many regions inhabited by Europeans such as Africa, China, South America, Australia, and New Zealand.

Theater was now powerfully influenced by the Industrial revolution, the emerging middle-class, and the increasing ability to travel. No longer were local theater companies the only option for theatergoers.

Today it is common to see theatrical productions from around the world and for world theater to be directly influenced by global events. Western theater continues to adapt to the sociopolitical climate. Whether occurring in large or small theaters, market squares, shopping malls, amusement parks, or site-specific spaces, Western theater remains dynamic and vibrant. Performers, story, and place remain essential elements shared with audiences who bear witness to the living culture of theater.

Asian Theater in General

Asian theater developed at a different pace and remained distinct from Western theater well into the twentieth century. It was known that storytelling, songs, and dance, were performed during early Asian times (c. 2500–1750 BCE) and documented evidence existed of cultural cross-pollination. Each Eastern culture developed and adapted its theatrical practices to reflect its own society, including the changes brought on by foreign or domestic upheaval. What remained consistent in Asian theater, perhaps in response to increased travel between India, China, and later, Japan, was the integration of dance and music.

India

Theater in India was originally influenced by Hinduism, the caste system, and Sanskrit literary traditions. Even today, the values of Hinduism pervade most Indian theatrical practices, especially the inclusion of themes that promote the ultimate goal of achieving union with the supreme world soul (also known as Brahman), which is infinite, indescribable, and perfect. In contrast, early Western theater in Greece portrayed the gods as finite, easily describable, and less than perfect. Indian Hindu theater is principally founded on two epics, the *Ramayana*, which is a story of 14 years of wandering by Prince Rama and his wife Sita (c. 500–200 BCE), and the *Mahabharata*, which is the history of various members of two ruling families. These early dramas were all defined by *Rasa*, which is a fundamental mood, rather than categories such as comedy or tragedy. All plays ended happily and death and violence did not occur on stage.

Similar to Western theater, Hindu theater used verse to express heightened emotion and prose for ordinary events. Sanskrit theater, known as *Natyasastra*, focused on performers and their talent for: (a) movement and gesture, (b) speech and song, (c) costume and makeup, and (d) psychological insight. Each of these categories was strictly codified according to character and caste; a codification that was also shared by much of the Chinese and Japanese theatrical traditions. Between the second and seventh century CE lower dramas (farces), shadow plays, folk plays, and more informal entertainment emerged. After the Muslim takeover in the twelfth century, drama became less widespread and formal theater was restricted to temples and festivals; however, a local form of theater, *Kutizatum* (a combination of secularism and eastern mysticism), did survive.

By the twentieth century, there were over 50 different forms of folk drama in India. Theater culture was influenced by Islam (c. thirteenth to nineteenth centuries), Portugal (from fifteenth to mid-nineteenth centuries), and France and England (eighteenth century). Theater was used as a tool to spread culture and solidify religious beliefs, especially as a means to inform a largely illiterate population. Although theater was influenced by religious teachings, it continued to follow earlier performance traditions: (a) stylized acting, (b) musical accompaniment for the full performance, (c) no scenery, (d) stage hands and stage managers appearing on stage but not acknowledged by the performers or the audience, and (e) performances starting late and continuing throughout the night. Small local theater companies developed more narrative dance and puppet theaters to facilitate easier access to remote communities. As Indian nationalism grew from the mid-nineteenth century, indigenous drama, opera, and dance regained popularity, as evidenced by a pattern of updating older stories into modern dramas (i.e., Bollywood theater). Today in India, theater is diverse, popular, and regarded as an emblem of national identity.

China

After the erection of the Great Wall of China, around 214 BCE, China became insulated from outside forces. A cultural schism developed between the North and the South which further diminished theatrical advancement. This pattern of unrest followed by stability was reflected in the theatrical practices. During periods of unrest only local variety-type entertainment was performed whereas in times of stability more complex cultural and scientific advancements took place. One such stable period (around CE 714), saw the establishment of the Pear Garden training institute, a school that facilitated innovative and popular theater. Today Chinese actors are still known as Pear Garden students just as actors in the West refer to themselves as Thespians. The new works developed at the Pear Garden were exported to Japan and other parts of Asia.

Gradually, the construction of buildings designated exclusively for theatrical productions emerged. Because of new printing inventions (movable type), Chinese tales were made widely available to theater companies, and were narrated by professional storytellers at Tea Houses or dramatized in puppet and shadow plays. Traveling theater troupes performed in Tea Houses, Goulans (theaters), as well as for the Emperor's birthdays. With the invasion of the Mongols, native Chinese intellectuals, now excluded from government, turned to culture, especially to music and drama. Despite social repression, a golden age of drama helped solidify Chinese theater. The plays were informed by history, with emphasis placed on loyalty to family and friends, devotion to work and duty, and justice. Both men and women performed and many of the companies were named for their leading actress. Elaborate costumes and makeup provided dramatic appeal.

Dramas in China were sophisticated explorations of morality and the human experience, although the stylistic form differed between the North and the South – the Northern style was traditional and the South was more avant-garde. In 1790, to celebrate the Emperor's birthday, artists arrived from all regions of the North and the South to perform. At this event, they combined their theatrical styles and called

it 'Capital Drama,' which later became known as the Beijing Opera. This new form was defined by rigidly controlled conventions of acting, dancing, singing, and movement. In Beijing Opera:

- the dramatic roles are divided into four main types – males, females, painted-face (subsidiary characters), and comic characters;
- each character describes themselves on their entrance;
- their movements are related to dance and/or mime;
- every gesture is symbolic and specific to each word uttered;
- the specificity of the symbolism is carried through in the costume design, accessories, and head-gear;
- rigorous training is required;
- different dialogues can be sung or spoken during the production and yet the audience understands the performance primarily through the movement vocabulary.

Since all regional Chinese drama integrated music and movement, when Western drama was introduced in the 1920s, this style of drama became known as spoken drama. Following the early roots of Chinese theater that began in Tea Houses, the practice of eating, drinking, and fluid arrivals and departures by the audience remains today, even for performances of spoken drama. Chinese theater remains vibrant, although like all world cultures, theater reflects the amalgamation of multicultural practices.

Japan

Early Japanese theater is shrouded in mystery until Buddhism was introduced in the sixth century. Prior to this period, what was known is that theater was related to Shinto rituals. With Buddhism came influences from many cultural traditions, especially from Korea, China, and India. By CE 1000, there were two types of theater, one to celebrate the harvest that was performed at Shinto shrines and the other to celebrate the ritual elements of Buddhism at Buddhist temples. At first, these ritual dance theaters were performed by priests but as they become more popular, professional performers were employed.

The rise of the Shoguns, in the twelfth century, brought about strict class structures (warrior, merchant, artist, and artisans, farmer and peasant classes), but by the fourteenth century, the artist-artisan class was eventually given protection and raised almost to the level of the Samurai Warrior. With this support, Noh theater came into being. In fact, all the permanent Noh dramas in repertory today were written in the fourteenth century. This form of drama grew out of the early acrobatic masked dances that were accompanied by songs and the ritual elements of Zen Buddhism. Noh classifications fall into five themes or categories of plays: (a) praising god, (b) warriors, (c) women, (d) deranged people or schemes of subterfuge, and (e) demons, devils and the supernatural. Noh performing style relies on indirectness, simplicity, suggestion, and restraint, with the focus given to movement and dance performed in slow motion. The stylistic elements of Noh theater persist, including:

- professional performers are almost always men;
- the lead character wears a mask but all other characters remain unmasked;
- to accompany the dances the chorus narrates and sings;

- there is no scenery;
- few props are used except fans;
- costumes are much simpler than Chinese costumes;
- there is minimal rehearsal since all performers have been well-schooled in their roles;
- between each Noh play short farces, called Kyogen, are performed.

This performance style and symbolic design made Japanese theater distinct from Chinese theater, including the demands placed on their audience to pay close attention (compared to Chinese audiences who came and went as they pleased).

Kabuki, a non-aristocratic form of Japanese drama, was established in the seventeenth century, a period of time when Japan moved deeper into isolationism. After the collapse of the Shogunate in 1868 other forms of Japanese drama such as Doll theater began to flourish. Both Doll theater and Kabuki presented sketches of domestic urban life. Originally, Kabuki was performed entirely by women; however, it quickly became synonymous with prostitution and so the performers were restricted to young men. The same problem of seductiveness persisted and so young men were also banned; performances were then relegated entirely to men who were required to shave their heads in an attempt to reduce sensual appeal. As Kabuki became popular, permanent companies performed a six-play season and employed a staff and playwrights (who were often also novelists or journalists), a practice that resembled European theater during Shakespeare's time. Most of the plays from the seventeenth century lasted approximately 12 hours divided into four sections.

At the same time as the fall of the Shogunates, many of the restrictions of the theater were lifted and by the latter part of the nineteenth centuries, women were once again allowed to perform, youth theater opened, and Western style drama was introduced. For the first time Japanese theater focused on more realistic presentations of drama. By the early twentieth century, Stanislavski's teaching had been adopted by Japanese theater practitioners and later, in the twentieth century, many indigenous theater artists, notably Tadashi Suzuki, adopted a unique eclecticism combining Method Acting technique with traditional Japanese stylistic elements. Today Japanese stage designs and performances embed religious symbols into contemporary themes. At its best Japanese theater reflects the simplicity of Eastern values with Western realism.

Africa

Africa, believed to be the continent from which humanity originated, was also the first known region to document theater. Egyptian writings from 4000 BCE recorded a rich culture of theater where the seeds of Eastern and Western traditions germinated. From its first productions to works performed today, African theater is marked by a rich confluence of song and dance that is fully integrated into storytelling and day-to-day African culture. The elements of physical gestures, rhythmic structures of dance and music, and narrative storytelling were never separated in African theater. From the small tribal community that gathers to celebrate or mourn, to the urban audiences that meet in large formal modern performance halls, African theater utilizes legends to explore the human condition and continues to maintain its close ties to music, dance, and storytelling.

Determining the roots of theater on the African continent is difficult to pinpoint due to the geographical remoteness of many regions, the multiplicity of languages, and the pattern of transmitting culture in non-written forms. Language had less importance in performance traditions than did music, dance, gesture, or mask, and audiences were part of the performance, in either ritual or ceremony. Most of African theater is deeply integrated into everyday life of the society; it is not a discrete event. Because much of Africa was subjected to religious and political colonization, the continent remains in flux. Borders shift to reflect the current political powers and with these changes traditional African theater (storytelling and long narratives passed down orally) has either been lost or truncated. Further, the slave trade greatly influenced the spread and dilution of cultures.

Tracing some of the African theater traditions requires exploring old kingdoms that existed pre-colonization. For example, the Northeastern section of Africa, comprising Egypt and many of the Arabic countries, followed Hellenistic (Greek) and Byzantine (Eastern) traditions. In Nigeria, theater occurred during funerals and other significant occasions and became the basis of Yoruba Opera (commonly known as Yoruba travelling theater that originated from the Oyo Yoruba kingdom and performed in regions where Yoruba-speaking populations reside). Similar to Yoruba Opera, the Gahanian 'concert party' used comedy and music to dramatize contemporary topics and to emphasize the need for a strong community. These objectives were amplified by the traditional practice of call-and-response interactions between audiences and storytellers. Much of the storytelling in Central Africa dealt with either fictional or historical events and retained a narrative rather than a dramatic structure (dramatization). These storytelling events were part of the early traditions of portraying rites of passage, crop gathering, and seasonal changes. They were performed in open spaces, with the audience encouraging or voicing skepticism and the performers responding with digressions and improvisations. As colonization increased in Central Africa, the storytelling included themes of oppression.

A large swathe of the Atlantic coast of Africa was heavily influenced by Portuguese merchants and their slave trade activities. Theater in these regions promoted the ideals of Catholicism, but once the African Atlantic seaboard countries gained independence, they adopted European theatrical forms while blending traditional tribal rituals as a way to rediscover their indigenous voice. Like other regions in Africa, South Africa experienced similar oppression; however, due to the conflicting interests and struggles between the Dutch and English a policy was instituted that forced native populations to relocate to territories (similar to the practices in North America where Native tribes were relegated to reservations). South African theater galvanized, responding to the injustices of the official government Apartheid policy. The theater community attempted to raise consciousness and demand equality, and with the eventual dissolution of Apartheid, coupled with the wealth of the region (particularly gold and diamonds), theater in South Africa became renowned for its strength of expression. Whether through government sanctioned Afrikaner theater, indigenous black companies working outside subsidized theater, or original companies established pre-Apartheid, South African theater is perhaps the most

successful at combining tribal traditions with European forms. South Africa remains a powerful example of the effectiveness of theater as a social movement.

In general, most indigenous African theatrical work was lost during colonization but what did survive is an emphasis on sacrifice, self-knowledge, and the divinity in all things. What has endured throughout Africa is the union of storytelling, song, and dance. Theater remains at the heart of African culture, a culture that embraces full participation from the performers and their audience.

Latin America

Like the continent of Africa, indigenous theater in South and Central America was powerfully influenced by the colonization of Spanish, French, and Portuguese cultures. Another integrative influence on theater was the importing of African slaves into South and Central America. Over time, these cultural values melded into powerful forms of theatrical events. Professional theaters and folk theaters influenced each other, although sadly few indigenous forms of theater remain intact today. What is clear is that borrowing models from other theatrical cultures was not done indiscriminately; they were adapted to effect change and draw attention to sociopolitical exploitation and marginalization.

For example, by 1765 Spain banned religious drama in an attempt to assert crown control over the church, a practice that generated great resentment and signaled the erosion of Spanish influence on Central and South American colonies. After Napoleon conquered Spain in 1808, satire was more open and sharp; playwrights used characters drawn from indigenous peoples and made comic heroes out of them, a style that strongly resembled the minstrel shows of the Southern United States. When Mexico secured independence in 1821, there was a strong need to promote local playwrights, in particular, plays that were rooted in comedy, melodrama, and satire. It was not until the First World War, when European companies could no longer finance tours in South America, that Latin America was able to establish its own theatrical identity, incorporating folk traditions and indigenous music.

Living Theater

Indigenous theater remains a powerful medium for communication. National, regional and local communities offer theatrical experiences as a positive vehicle for individual and social development and a viable means of expression for its members. Theater can be targeted to appeal to children, adolescents, the elderly and special interest groups (disability, sexual orientation, racial minorities) and it can be offered in diverse locations. The theatrical purposes range from pure entertainment to education, including propaganda.

Since the beginning of theater, communities have sponsored festivals that feature professional and community theatrical groups. People gather to witness and share in these massive events. One of the most popular and perhaps the largest such festival is the Edinburgh Festival, with over a hundred events occurring in multiple venues located throughout the city. Similar popular and successful theatrical festivals

take place on every continent of the world and attract audiences and performers from diverse economic and social backgrounds.

Seismic shifts in theater persist; however, according to Martin Esslin, what endures is a pattern of change that is either externally focused on the social-political structures of the community or the internal psychological reality of the character. Major theatrical movements that reflect these two patterns can be illustrated in Brechtian theater, where the stage became a platform for social research and experimentation versus Theater of the Absurd (Camus, Sartre, Beckett, Pirandello), in which a vocabulary and stage convention developed to portray the interior mind of the characters. Other theatrical shifts emerge through merging existing conventions into a unique 'new' genre. Such a result is evident in today's Musical Theater; although its early roots can be traced to the British Musical Hall, vaudeville, burlesque, pantomime, and operetta. In fact, theater began with an integration of music and dance and only later did they become separate art forms.

Theater is multidimensional; many things happen at the same time such as dialogue, suspense, timing, context, and levels of discourse between the characters, the characters and the playwright, the characters and the actors, and the characters and the audience. During a theatrical event, something happens, even if everyone continues *Waiting for Godot*.

Theater as Healing and Theater as Witness

Theatrical experiences can promote healing. For example, youth theater programs are designed to help develop competencies, increase feelings of self-worth, and encourage the recognition of strengths and assets. Plays are written specifically for children and adolescents and performed to engage and to educate. According to Carol Lorenz, a significant shift took place during the 1960s, one in which playwrights began to portray the young as psychologically and intellectually complete human beings, whose experiences deserved to be told. Susanne Dutton pointed out that using arts in the field of social work is a common practice, especially in settlement houses. In these settings, at-risk youth are given opportunities to explore problems and conflicts through interactive efforts to create and perform theater works that speak directly to this age group and to the issues that are troubling them.

The originator of psychodrama, J. L. Moreno, moved away from the practice of playwrights constructing drama. In psychodrama, the performers and the audience are actively engaged in the creative process of improvisation. According to psychodrama theorists (Kipper, Hundal, and Shemer), spontaneity serves as a measure of mental health. Theorists such as Abraham Maslow shared the belief that spontaneity is related to psychological health, believing it to be a necessary condition to attain self-actualization. According to Phil Jones, drama therapists determine effective therapy by observing and evaluating core processes including:

- dramatic projection (individuals can take on fictional characters or roles and project themselves into the dramatic material);

- dramatic performance and therapeutic empathy and distancing;
- role-playing and personification;
- interactive audience and witnessing;
- embodiment;
- playing life-drama connections;
- transformation.

Moreno's concept of vibrant role-playing is evident in all psychodrama programs, especially those found in educational theater, theater of the oppressed, and playback theater.

Theater of Witness further integrates theater with theories and treatment practices gleaned from trauma specialists. Theater of Witness practitioners believe that theater offers a place for the collective integration of traumatic memories, a practice that goes back to the beginning of time. In fact, the earliest form of Theater of Witness is found in Ancient Greek theater; the chorus, innocent of all crimes, witnessed, protested, and lamented the tragedies of its citizens. According to Aristotle, the purpose of tragedy was catharsis, a concept that was fully embraced by Freud in his psychoanalytic therapeutic talking cures. The goal is to transform inner experiences, especially experiences of violence, incest, and revenge. Theater of Witness is a genre that operates around the world through such organizations as the Playhouse of Derry and the International Trauma Studies Program. Initiatives are undertaken to engage intergenerational cross-community groups to portray their own journey of reconnection, reconciliation, healing, and acceptance in performances that are raw, honest, and powerful. The intent of this form of theater is to provide people a forum to ease their pain and hurt while simultaneously transforming these hurts into narratives that are witnessed by others.

According to Ellen Kaplan, creating theater that is rooted in personal story is best managed by oscillating between empathy and distance. This oscillation facilitates the healing power of traumatic stories. Post-apartheid South Africa is a vibrant example of theater as a tool for the recuperation of politics and culture. It recounts stories of unspeakable cruelty, lets sufferers know that they are not alone, and provides models for how to survive. Further, according to Stephen Wangh, unlike psychoanalytic writers who tend to avoid discussions on forgiveness, playwrights, especially those involved in theater of witness drama, frequently depict forgiveness as a psychological means to resolve cycles of anger and revenge, emotions and intentions that can leave survivors stuck in life-threatening behaviors.

Many theater educators are now offering courses in Theater of Witness including California Institute of the Arts, University of Cape Town, and NYU. In these classes, students are asked to face the current and continuing suffering of individuals and communities around the world. They are asked to bear witness to contemporary genocides and to describe what they learned in the process of exploring these topics. They integrate (a) literary theories of witnessing and testimony, (b) historical and political backgrounds that led to atrocities, and (c) psychoanalytic theories that diagnose and treat trauma survivors.

Further Research Studies in Theater

Theater is an ancient practice that exists worldwide. It is a dynamic relational art form that places audience participation

in a central role. Paul Sullivan and John McCarthy have eloquently argued for research that accounts for the lived experiences of artists and their audiences. They call for an examination of esthetic experience as it unfolds; a dialogical engagement between artwork and audience. Keith Sawyer and Stacy DeZutter argue that theater may be better understood as 'distributed creativity,' a theoretical framework that explains theatrical processes that are collaborative in nature in which a shared creative product is generated. They propose that through an interdisciplinary combination of interaction analysis and qualitative methodologies researchers will be better able to gather findings that explain creative processes that are always distributed amongst those engaged in the creation of theatrical productions, a practice that Sawyer's implemented while investigating 'improv' theater.

Researchers, like James Kaufman, have demonstrated that playwrights, although not as pronounced as poets, are vulnerable to shortened life-spans, emotional disturbances, and more personal tragedies than nonartists. Thomson and Jaque found that actors had increased vulnerability for dissociative disorders as compared to a healthy control group, a result that echoes Kaufman's findings for playwrights. Kogan and Kangas found that actors, directors and playwrights, although thoroughly trained and practiced, are often late-bloomers, as compared to other artists in the performing arts. Further, they found that theatrical experience prior to university was a strong predictor for a career in theater. Nancy Andreasen, in her book, *The Creating Brain*, recounted a conversation with Neil Simon, one of the great twentieth century playwrights. Simon claimed that he "slips into a state that is apart from reality," "I don't write consciously – it is as if the muse sits on my shoulder," "my mind wanders – even when I talk," and "I've always felt invisible." Andreasen cited researchers whose work offers explanations for Simon's comments, including cognitive patterns of divergent thinking, less cortical inhibition of sub-cortical processes, and dissociative behaviors that promote detachment and altered states.

On a different note, Canadian researchers have adopted a unique investigative stance to gather data. They have literally staged data and used theater as a tool for analysis and knowledge transfer in health research. Since theater engages complex questions of the human condition it can communicate health-based information to communities and shape awareness and understanding. This approach reinforces the theoretical approach of Zorana Ivcevi and others who claim that since creativity exists in space and time, any discussion of creativity must begin with a definition of creativity and situate the research in relationship to the definition. Regardless of methodology and research design, what remains challenging for anyone investigating theater is the breadth of this topic. As a result, research in theater remains as broad as the topic itself.

Conclusion

Theater is a shared event that presents human experience in the present moment. Theater-making is created in community and the place for the storytelling is the theater. Humans are storytellers and these shared stories record our history and culture; they help define our humanity as we navigate through time

and place. Whatever the physical and geographic location, theater has an artistic life only when occupied by a performer, an audience and a story to be told. Theater may portray the traditional Western perspective of conflict, change, and progress with humanity as the principle agent for good and evil, or the Eastern view that humans seek to transcend temporal limitations and achieve union with the mystery of being. Regardless of perspective, genre, or stylistic form, theater remains dynamic. It reflects cultural values and unifies community; it remains a vibrant expression of our humanity.

Theories of Creativity

Glossary

Accuracy One criterion for evaluating the usefulness or success of a theory, in terms of the extent to which it accounts for observed data.

Armchair speculation A colloquialism for a first-person, subjective understanding of the nature of creativity, which is not explicitly elaborated into a set of testable hypotheses or subjected to empirical study. Prior to the advent of modern scientific methods of studying creativity, such speculation was the primary way the topic of creativity was understood. A number of historical creators have provided records of their thoughts on the topic in this way.

Fruitfulness Another criterion for evaluating the usefulness or success of a theory, in terms of the extent to which it identifies new phenomena or relations between phenomena and generates testable hypotheses.

Metaphorically oriented theories Theories that offer a somewhat speculative stance focusing on provoking new

understandings and possibilities, rather than on rigorously accounting for phenomena.

Reliability A criterion for assessing the measurement of some construct, concerning the consistency of a set of measures.

Scientifically oriented theories Theories that have an underlying goal of mapping the empirical reality of creative phenomena and that aspire to traditional scientific standards: a search for objective truth, generating empirically falsifiable hypotheses, and developing formal or computational models.

Theory Generally speaking, a collection of concepts, together with rules expressing relationships between such concepts, which account for empirical data and make predictions about future observations. In creativity research, theories may be heuristically divided into more scientifically-oriented theories and more metaphorically oriented theories.

Validity A criterion for assessing the measurement of some construct, concerning the accuracy of measurement.

Introduction

For millennia, human beings have pondered the nature of creativity. Much of this speculation has accompanied and served as commentary on the spectacular creative achievements of our species, with creators themselves often furnishing detailed descriptions and explanations of their own creativity. Until fairly recently, theoretical conceptions of the nature of creativity have been rooted in first-person introspection or on case-study-like familiarity with the works of a small number of creators. However, in the last half century or so, scholars and researchers – mainly from psychology, but from other domains as well – have tried to advance on this armchair tradition. They have applied more rigorous research methodologies, increasingly sophisticated analytic techniques, far richer datasets, and (often) a pragmatic, applied orientation. Importantly, their approaches have also been informed by and grounded in knowledge from other relevant domains – including, but not limited to, subdisciplines within psychology. The resulting surge of research activity has yielded a diverse array of theoretical approaches for understanding creativity. The purpose of this article is to describe contemporary theories of creativity and, at the end, to offer a critical but hopefully constructive appraisal of current theories and their promise for the continued informing of the nature of creativity.

Ways of Understanding Theories of Creativity

Pluralism

A generous-spirited way of understanding contemporary research about creativity is to emphasize *pluralism*, whereby a multitude

of perspectives, with different assumptions, definitions, and methods, operating at different levels of analysis, and making connections with various other disciplines, all contribute to a robust understanding. However, when faced with an array of perspectives, the need to characterize commonalities among theories, while still recognizing differences, becomes apparent. Here, to set the stage for an exposition of the main categories of creativity theories, four such frameworks are discussed: a more scientific versus a more metaphoric quality, a purely theoretical versus applied focus, level of creative magnitude, and emphases among the so-called six P's of creativity. While there is some overlap among these four, they may be regarded as largely independent, so that any particular theory can address any combination of the levels of these frameworks.

Scientific Versus Metaphoric Theories

One common distinction, in many areas of study, is between more overtly 'scientific' theories versus more metaphorical ones. Scientifically oriented theories have an underlying goal of mapping the empirical reality of creative phenomena and aspire to traditional scientific standards: a search for objective truth, generating empirically falsifiable hypotheses, and developing formal or computational models. In contrast, metaphorically oriented theories offer a more speculative stance focusing on provoking new understandings and possibilities and offering a moderating counterbalance to the sometimes stark empirical focus of scientific theories. Such theories are of maximal use when they balance speculation with agreed-upon methods of empirical exploration and peer review. The varied, complex, interdisciplinary quality of creativity naturally lends itself to exploration by both kinds of theoretical orientations.

Purely Theoretical Versus Applied

Creativity researchers have varied goals. For some, it is understanding creativity as its own phenomenon, in a disinterested, 'pure' scientific way, without any overt interest in the practical applications or implications of discoveries. Others' goals are more explicitly pragmatic – usually, to increase creativity by identifying factors associated with its natural development (and to create environments with such characteristics) or by designing specific interventions to promote creative thought. While some theories focus more on one than the other, most have implications for both pure and applied research.

Levels of Creative Magnitude

Another framework concerns what may be called level of creative magnitude. Not all instances of creativity are equal. A standard distinction is between 'Big-C' (truly great, history-making instances of creative breakthroughs among eminent individuals) versus 'little-c' creativity (a private minor insight or realization in an ordinary person). In recent years, two additional categories of creative magnitude have been proposed: a 'mini-c' category provides more room for subjective or personal instances of creativity; a 'Pro-C' category allows for professional-level creators who have not yet attained eminence, but who are well beyond little-c creators in knowledge, motivation, and performance.

A focus on a particular magnitude will constrain a researcher's basic questions, sources of data, and methodologies. Since they are by definition less common, widely acknowledged Big-C or Pro-C achievements are more often approached by the analysis of archival data (creative products, laboratory notebooks, sketches, etc.) or by carefully targeted laboratory or case study investigations of select individuals. In contrast, little-c and mini-c creativity lend themselves to more varied methods, including laboratory experiments, paper and pencil surveys and inventories, microgenetic studies of creative behaviors, and introspective self-reports of the subjective aspects of the creative experience.

The Six P's of Creativity

Another common framework for capturing different aspects of the phenomenon of creativity is the so-called six P's of creativity: *process, product, person, place, persuasion, and potential*. Since this alliterative framework nicely organizes many issues in the study of creativity, it is a useful way to compare the scope of different theories.

Theories that focus on the creative process aim to understand the nature of the mental mechanisms that occur when a person is engaged in creative thinking. Process theories typically identify different specify stages of processing or particular mechanisms as the components of creative thought. Another approach focuses on creative products: works of art, inventions, publications, etc. Products can usually be counted, permitting quantitative objectivity, and they are often available for judging, so inter-rater reliability can be readily determined – two substantial advantages; however, products themselves say little about their creators or the creative process that engendered them.

Studies of the creative person (or personality) tend to focus on identifying and understanding individual difference traits that are associated with creativity, such as intrinsic motivation, wide interests, openness to experience, and autonomy; some traits also seem more pervasive either among persons in artistic or scientific domains. The actualization of creativity also depends on the place or setting in which an individual resides. Research on place factors is especially useful in defining such interactions between persons and environments, which tend to be optimal for creativity when there are opportunities for exploration and independent work and when originality is valued.

Another view describes creativity as persuasion: creative people change the way others think, so they must be persuasive to be recognized as creative. This notion shares assumptions with a number of theories, including Mihalyi Csikszentmihalyi's systems model (described below), in which persuasive individuals are the ones who influence the direction taken by a domain. Finally, the notion of creative potential addresses the need to examine and understand the latent capacity for creative thought in children and others, who may have what it takes ultimately to be creative, but who require educational opportunities or other support before they can do so. Obviously, the goal of realizing creative potential is a major goal in education, so studies of creative potential often have a strong practical focus.

Categories of Theories of Creativity

Overview

Ten major categories of theories are now described: *Developmental, Psychometric, Economic, Stage and Componential Process, Cognitive, Problem Solving and Expertise-Based, Problem Finding, Evolutionary, Typological, and Systems*. The goal is to provide a big-picture overview of each type. Most theories described here have been discussed in the literature for at least several decades, boast considerable research support, and span multiple P's, levels of analysis, and methodologies. Excluded are theories that are limited to understanding a fairly narrow aspect or subtopic – such as creativity's relation to mental illness or to personality, its biological underpinnings, cultural differences in creativity, and so on.

Developmental Theories

Developmental theories pragmatically aim to understand the roots of creativity, as suggested by the backgrounds of Big-C creators, but they also often suggest how to design environments to fulfil creative potential. They mainly emphasize the person, place, and potential aspects of creativity, and range from mini-c to Pro-c. Early developmental theories were devised by examining the lives and backgrounds of eminent creative persons; these suggested that particular developmental experiences were correlated with later creativity, such as exposure to diverse experiences and not being overly restricted.

Other theories focus on family structure (e.g., birth order, ordinal position within the family, age interval between siblings, etc.). For instance, evidence suggests that middle children often rebel against their parents and the *status quo*,

to attract attention away from older siblings whose maturity earns them praise. Rebellion may occur within the context of the family, in one's thinking, or, during adulthood, in artistic or scientific revolutions.

Longitudinal methods provide another powerful perspective on development. Findings from this tradition indicate that during their childhoods, the truly gifted had the support to make cognitive and emotional transitions – one from general to creative talent, and the other from capability to a motivational state which leads directly to actual achievement. Such studies reinforce developmental theories of creativity that take into account cognitive processes, motivation, affect, and personality.

Psychometric Theories

Psychometric theories focus on measurement, and as such they inform all other creativity theories. Emphasizing products over the other P's, they range from little-c to Big-C creativity and are concerned, among other things, with the reliability (agreement or consistency of measurement) and validity (accuracy) of assessment, which are issues in all creativity research. Besides establishing basic principles of the measurement of aspects of creativity, psychometric theories have also addressed issues like how creativity differs from intelligence, the relation between performance on convergent thinking (one right answer) tasks and divergent thinking (many correct answers) tasks, and the extent to which creativity is rooted in particular domains of activity (like music, mathematics, or writing) versus being a domain-general ability.

Economic Theories

Another category of theories draws on economic metaphors. The macro-level quality of these theories encompasses all of the P's except process, and spans little-c to Big-C creativity. There are several economic or investment theories of creativity. Some describe the market for creativity, which illustrates macro-level processes and interactions involving the allocation of resources. Markets can provide benefits to certain behaviors or impose costs upon them, which can be defined in psychological terms. Other research has examined the market for creative behaviors, going so far as to define a creative class or segment of society, and arguing that a key component of the market for creative work is tolerance; unconventional people sometimes need to be tolerated, and creative societies do a good job of that. Other work has emphasized investments in creative behavior, in particular that creativity can result when a person buys low (i.e., invests in an idea which is currently unpopular) and then sells high (i.e., the idea gains respect).

Stage and Componential Process Theories

As noted earlier, many models of the creative process have been proposed. Some attempt to understand the creative process in terms of stages, which can be sequential or recursive; others focus on underlying componential cognitive processes. Such models range from mini-c to Big-C creativity and obviously emphasize process over the other P's.

Stage theories usually try to understand how moments of creative insight occur, typically by positing a particular sequence of processes – for instance, Graham Wallas's venerable model of preparation (gathering information and defining a problem), followed by incubation (taking some time away from the problem), followed by illumination or insight (having a sudden realization of the answer), followed by verification (applying the solution). Since the linearity of such models has been largely discredited, more recent stage models have acknowledged the need for recursion, whereby an individual may cycle through the stages multiple times, in various combinations.

As an alternative to sequential or recursive stages, some recent theories have defined the creative process in terms of component mechanisms or processes, which operate in a more inter-connected manner. Various componential frameworks emphasize factors like domain-relevant skills, cognitive style, knowledge of heuristics for generating novel ideas, attitudes towards specific tasks, and perceptions of one's motives, and how these components interact to generate novelty.

Cognitive Theories

Cognitive theories emphasize the creative process and person: process, in emphasizing the role of cognitive mechanisms as a basis for creative thought; and person, in considering individual differences in such mechanisms. Some cognitive theories focus on universal capacities, like attention or memory; others emphasize individual differences, like those indexed by divergent thinking tasks; some focus on conscious operations; others, on preconscious, implicit, or unintentional processes.

One classic cognitive theory, by Sarnoff A. Mednick, argues that creative insights can result from associative processes in memory. In this view, ideas are chained together, one after another, and more remote associates tend to be more original. This perspective argues that more creative individuals tend to have flatter hierarchies of associations than less creative individuals; in other words, more creative people have many more relatively strong associates for a given concept, rather than only a few. This is thought to provide greater scope for the simultaneous activation of far-flung representations, which many believe to be an important engine of creative thought.

Along similar lines, another cognitive theory focuses on how concepts are combined to generate novelty. Research suggests that conceptual combination – bringing two different sets of information together – is often involved in creative ideation, that original insights are more likely when two disparate features are brought together, and that connections between these concepts might only be seen at a very high level of abstraction. This kind of thinking has been called metaphoric logical, the idea being that something like 'angry weather' is only comprehensible in a nonliteral fashion. Such processes may suggest creative alternatives to well-worn lines of thought.

More generally, research in the 'creative cognition approach' tradition, another important contemporary view of creativity developed mainly by Ronald A. Finke, Steven M. Smith, and Thomas B. Ward, has likewise emphasized ideas drawn from cognitive psychology (e.g., conceptual combination, conceptual expansion, creative imagery, and metaphor) to understand how individuals generate ideas and explore their implications in laboratory-based invention and design tasks. Such processes

are thought to play out in two fundamental regimes of thought: generating ideas and exploring their implications. In practice, the two are strongly interleaved and combined in the 'geneplore' model of creative thought (from *generate* + *explore*).

Finally, metacognitive processes (thinking about one's own thinking) are also frequently tied to creativity. Many tactics for increasing creative problem solving have been proposed and popularized, including 'think backwards,' 'shift your perspective,' 'put the problem aside,' and 'question assumptions.' Tactical thinking is especially useful for programs designed to facilitate creative problem solving since they are a function of conscious decisions and can be employed when necessary.

Problem Solving and Expertise-Based Theories

A related major category of creativity theories, again drawn from cognitive psychology and most apparent in the research of Nobel Laureate Herbert Simon, emphasizes problem solving processes and expert knowledge. This is largely a theory of the creative person and process: person, in emphasizing domain-specific expertise as necessary for significant creative achievements; and process, in emphasizing how traditional cognitive psychological concepts like problem representations and search through problem spaces explain how people devise creative solutions to problems. Such principles can be readily applied to ill-defined problems, which are under-specified and which admit multiple 'good enough' solutions, rather than one 'correct' answer. Ill-defined problems can often be broken into several well-defined problems, which can then be solved in familiar ways. Moreover, one can search not only for a solution, but also for a way to formulate a problem.

The problem solving/expertise view boasts considerable support, from many lines of evidence. Many of the processes and structures described in the creative cognition approach can be straightforwardly related to those of the problem solving/expertise view. Archival studies of great creators reinforce the importance of domain-specific knowledge for high-level creative achievement, for instance in the so-called 'ten-year rule,' whereby at least a decade of intensive work in a domain is required before a creator produces any original works of lasting value. The archival study of creative episodes taken from the notebooks of eminent scientists has also generated a number of computational models of the creative process, which have replicated many major scientific discoveries.

Overall, the problem solving/expertise view regards creativity as a largely rational phenomenon, in both being amenable to rigorous empirical study by researchers, and to meaningful strategic guidance and long-term learning by creators themselves. Thus, another advantage of this view is pragmatic: its foci are strategic factors that individuals can partly control; at the same time, the problem solving/expertise view acknowledges that Big-C problems are extremely difficult.

However, this view has some limitations. For instance, expertise is a necessary but not sufficient condition for Big-C creativity; many other factors also contribute to high-level creativity. Also, the expertise view arguably overstates the role of cumulative deliberate practice, at the expense of talent. Finally, some have criticized the computational approach to creativity as fundamentally misguided.

Problem Finding Theories

Problem finding, another influential view of creativity, originally postulated by Jacob W. Getzels and Mihalyi Csikszentmihalyi, can be seen as a reaction against the traditional problem solving approach to creativity. The problem finding view holds that the problem solving view is inadequate to explain how creators come to realize that a problem exists in the first place and how they are motivated to bring their subjective experience to understand the problem. Problem finding is often regarded as independent of problem solving, and it is mainly as a theory of the creative process; it can also be seen as a theory of the creative person. In terms of creative magnitude, problem finding can often be construed as an instance of mini-c creativity, though there is also room for higher levels.

Early research on problem finding focused on understanding the exploratory behavior of creative visual artists, with a strong emphasis on their motivational factors and existential concerns. Since problem finding is more subjectively-oriented and harder to define than problem solving, it is more difficult to cite evidence definitively bearing on problem finding, either pro or con. The problem finding view may also overemphasize on-line discovery, at the expense of considering habitual behavior patterns.

Overall, the distinction between the problem solving and problem finding frameworks may be less due to substantive differences between the theories and more a matter of the taste of individual scholars. In any case, more recent models have often focused less on such labels and more on the nature of the underlying processes, using terms like 'problem construction' to encapsulate the constellation of processes involved in coming up with a creative solution to an ill-defined problem.

Evolutionary Theories

Researchers have proposed several theories of creativity drawing on ideas from evolutionary biology. Of these, a strong candidate for the most comprehensive general theory of creativity is the Darwinian model of Dean Keith Simonton, which, to varying extents, covers all of the P's of creativity: person and potential, in identifying dispositional and developmental idiosyncrasies associated with the realization of initial creative potential into actual creative achievements; process, in laying out a two-step model of ideation and elaboration, in which chance combinations of ideas play a paramount role and whose complexities are hard to control; product, in noting sometimes unreliable initial assessments versus longer-term stable judgments of creative artifacts; place, in identifying social factors leading to outstanding creativity; and persuasion, in emphasizing how social dynamics establish verdicts of creative outcomes. More than any other theory, Simonton's Darwinian view aims to understand the nature of genius, eminence, and Big-C achievements.

The basis of the Darwinian model is a mental process involving the blind generation and selective retention and elaboration of ideas. Ideas are combined in some blind fashion, typically below the threshold of awareness; the most interesting combinations are then consciously elaborated into finished creative products; these in turn are judged by other people. This process can be elaborated into a mathematical

model that accurately describes how creative productivity unfolds over the lifespan, and a great deal of quantitative archival evidence supports the predictions of the theory. Indeed, in general, it is probably fair to say that the model's quantitative basis gives it a rigor unsurpassed by any other major theory of creativity.

The Darwinian view has major psychological implications. Given the complexity of the creative process, creators should have little control over guiding the progress of their works. Creators should also not be particularly good judges of their ideas or works. Moreover, once works are finished, creators have little control over their fates, since this is a social judgment; thus, mass-production is the optimal strategy for those seeking eminence.

Despite its comprehensiveness, the Darwinian view can be critiqued along several lines. It arguably overemphasizes the role of chance factors in explaining creativity. Also, despite its mathematical parsimony, process particulars are left unspecified. Moreover, an array of theoretical arguments has also been offered that dispute fundamental premises of the Darwinian view, as well as objections based on empirical data that do not conform to the predictions of the theory. Finally, however well the Darwinian view works as a first approximation to many phenomena in the study of creativity, it explains little of the considerable error variance in relations between productivity and eminence, age and productivity, the production of masterworks versus minor works, or in creators' varied career trajectories. Understanding such individual differences is a focus of the next category of theories.

Typological Theories

One approach to understanding variation in creators' personalities, working methods, and career trajectories has been to posit typologies of creators, who differ in systematic ways. A number of such frameworks exist, many of which have elements in common; however, at least as often, they differ in their particulars, so that different typologies can be difficult to relate to one another. As a group, however, typological theories differ from the nomothetic (or universalist) emphasis of other theories, in aiming to explain variability among creators rather than overall trends. Various typologies touch on aspects of all of the P's and levels of creative magnitude.

Typologies are most often cast as a set of categories, often construed as mutually exclusive. This is convenient for readily understanding the big picture, but it may be misleading when a typology is generalized too broadly, or individuals are made to try to fit into a category they may only partially exemplify; this latter point also raises the issue of potentially poor reliability in categorizing individual creators. Setting up mutually exclusive categories is also limited in excluding the possibility of an underlying multidimensionality, which can seem antithetical to the multifaceted nature of creativity.

An alternative is to cast individual differences not in terms of categories, but in terms of multiple continuous dimensions, which creates a space of possibilities in which a particular creator can be located. Going even further, at their best, typological theories not only note the factors along which creators differ, but attempt to relate these factors to each other across multiple levels of analysis.

Considered as such, typological theories are among the most promising for achieving a richly integrated, multilevel understanding of creativity, as creativity research moves forward. Not the least virtue of such an approach is the potential rapprochement between historically opposed camps in the study of creativity, such as the problem solving/expertise and Darwinian approaches, both of which can be at least partly absorbed into typological models. It is debatable whether such a unified theory of creativity is possible – or even desirable, from the standpoint of pluralism raised at the outset of this article. However, taking into account the unique and highly varied characteristics of individual creators is an issue that any comprehensive account of creativity ultimately has to face. These higher-level themes are also characteristic of our final category of models: 'systems' views of creativity.

Systems Theories

Some of the broadest and most ambitious theories of creativity take the view that creativity is best conceptualized not as a single entity, but as a phenomenon emerging from a complex system with interacting subcomponents. Such 'systems' theories take a broad and often quite qualitative contextual view of creativity. A number of such theories have been proposed, almost all of which address each of the P's, though with different emphases, depending on the relevant level of creative magnitude.

One influential systems theory, devised by Mihaly Csikszentmihalyi, takes as its starting point not the question, "What is creativity?" but rather, "Where is creativity?" In this view, creativity emerges via three interacting components:

1. the domain, or body of knowledge that exists in a particular discipline at a particular time;
2. the individual, who acquires domain knowledge and produces variations on the existing knowledge; and
3. the field, comprised of other experts and members of the discipline, who decide which new works are worth preserving for the next generation.

Each has a role in determining what counts as creative.

This perspective involves multiple factors and takes a very broad view of creativity, emphasizing the ubiquitous role of place (or environment) among the P's, especially for Big-C achievements. It also elaborates the nature of the creative person by detailing how individuals other than the creator contribute to the emergence of creativity and de-emphasizes internal processes and individual contributions, placing more stress on collaborative creativity and the societal conditions which can best foster genius. It likewise highlights issues like the importance of 'gatekeepers' (e.g., journal editors, gallery owners, etc.) who play a major practical role in determining which contributions will be given the opportunity to be judged as creative.

This framework has many advantages, not the least of which is acknowledging the importance of extra-personal, sociocultural factors, which were previously underemphasized in creativity research. However, the qualitative nature of the model makes it difficult to test hypotheses unambiguously, and its strong interdisciplinarity could be a pragmatic roadblock – though for a rich understanding of creativity, many

more variables and levels of analysis need to be considered besides a quantitative, empirical approach to individual traits.

An alternative systems view, pioneered by Howard E. Gruber, is the 'evolving systems' approach. This has mainly been applied to understanding the unique attributes of the creative person, via detailed archival case studies, which are motivated by a particular question – for instance, how Darwin devised the idea of evolution by natural selection. Such case studies focus less on understanding the particulars of one creative act than on how those particulars fit into an individual creator's goals, knowledge, and reasoning, plus larger social forces and creative paradigms.

The emphasis of the evolving systems approach is on dynamic, developmental processes that play out in complex ways and contexts, over varied timescales. Several key concepts provide a framework for understanding creative individuals in the midst of such complexity. One is the notion that great creators use an 'ensemble of metaphors' in their thinking, which together characterize a developmental process leading to creative meaning-making. Another is that of a 'network of enterprises,' a system of goals that describes how an eminent creator may work on seemingly disparate topics and projects, consecutively or concurrently, and continually evolve a sense of the relations between the topics. Such analyses put considerable interpretive pressure on researchers, particularly in absorbing the details and global qualities of a large amount of material and in avoiding pat, hindsight-biased conclusions about a creator's entire career. However, if used judiciously, this method has the potential to characterize a creator in a dynamic way with a qualitative richness and rigor that is probably unmatched by any other approach.

Future Directions for Creativity Theories

Pluralism – Again

At the outset of this article, pluralism was put forth as a way of celebrating the diversity of creativity theories currently in the literature. The principle of pluralism may also prove useful in guiding future directions as scholars develop, refine, and connect theoretical perspectives. Such connections between different theoretical perspectives could potentially lead to attempts at grand, unified theories of creativity; however, unified theories or not, making connections would strongly benefit creativity research anyway, as researchers better situate their theories in the broader theoretical and empirical character of the domain, acknowledging and incorporating the plurality of perspectives that have taken root and flourished. This applies to all of the principal frameworks outlined earlier – including the six P's of creativity, the various levels of creative magnitude, a pure research versus applied focus, and a more scientifically oriented versus metaphorically oriented approach.

What Do We Know? A Critical Reconsideration of Theories of Creativity

In the light of the preceding exposition and discussion of current theories, let us revisit a theme somewhat related to the scientific-metaphoric distinction: the question of what researchers have actually learned about the nature of

creativity, and what role theories have played in that process of discovery.

Creativity researchers are in a somewhat uncomfortable position. At any level of magnitude, creativity by definition involves variety and unpredictability, which raises a host of conceptual, methodological, and measurement complications. Beyond that, a more subtle, but also more insidious, issue is that creativity as a topic of study is not some independent natural science phenomenon, whose physical workings can gradually be understood in reasonably objective terms. Rather, creativity is an all-too-human enterprise, one which our most illustrious forbears – Newton, Michelangelo, Mozart – probably had a far richer experience of – and, perhaps, deeper knowledge of – than virtually any contemporary creativity researcher.

This simple observation presents enormous conceptual and practical difficulties. This is especially true for researchers of Big-C Creativity, who must grapple with phenomena of unmatched depth, richness, and complexity, and who must achieve some multidisciplinary understanding of the particulars of the domain of expertise of their subject. (The issue is somewhat less threatening in the realm of little-c creativity, since the creativity of researchers can – hopefully – reasonably be expected to exceed that of most of their subjects.) It is an open question, to what extent any contemporary theory is a substantive improvement on the best armchair speculation antedating the modern psychological approach to the study of creativity. Indeed, from a hard-nosed, ultra-scientific perspective, many so-called 'theories' of creativity are arguably not well articulated or substantive enough to be informative about the phenomenon one way or the other.

The written record of eminent creators' armchair theorizing about creativity thus stands as an elephant in the creativity theory room. If the study of creativity is to be scientifically respectable, it surely needs to go beyond what could merely be arrived at by intuition, like any mature empirical discipline. This includes making falsifiable and counterintuitive predictions (not just commonsense postdictions), as well as making contact with well-developed neighboring domains and spanning multiple levels of analysis. Doing so need not imply a single unified theory of creativity or an abandonment of metaphorically oriented theories, but it does require high critical standards. A well-developed theory of creativity also does not entail making error-free predictions. In many ways, the domain of creativity research is more similar to contingency-intensive disciplines like history or biology, both of which have seen the development of rigorous, beautiful theories with great explanatory power, even if they cannot literally predict the future in great detail.

In considering the prospects and nature of reasonably rigorous theories of creativity, several criteria for the value of a theory are worth remembering. One is accuracy, or correctness: Does a theory make good predictions and yield reliable knowledge about a phenomenon? Another, however, is fruitfulness: the capacity of a theory to disclose new phenomena or relations among phenomena and to generate testable hypotheses. Some very accurate theories are sterile; some wrong theories are nevertheless very generative. In the history of science, many wrong ideas have been enormously useful, if only because the process of disproof can lead to greater knowledge and integration. For a topic like creativity, where precise predictions may not

be a reasonable goal, fruitfulness may be the better criterion of a theory's usefulness.

How have current theories of creativity fared by these two criteria? Given the complexity of the phenomena of creativity, it is encouraging that many contemporary theories are able to do a reasonable job accounting for existing data. However, ironically, despite the variety and number of theories in the literature, it is not clear that they do well by the criterion of fruitfulness. For instance, it does not seem unreasonable to claim that a book like Eckermann's *Conversations of Goethe* contains more wisdom and would spawn more hypotheses about the nature of creativity than virtually any contemporary psychological overview.

Along these lines, it is also arguable that what is really needed to advance the study of creativity is not a proliferation of more theories, but instead, more, better, and richer data, which could be used to put useful, direction-providing constraints on existing theories. Allied to such datasets, the application of more sophisticated statistical methods – including latent variable models and hierarchical or multilevel analyses – would go a long way to documenting and enabling an understanding of the richness of creative phenomena. Importantly, these would also serve to encourage the development of theories that were conceptually equipped to take advantage of such added empirical rigor.

In terms of subtopics within the study of creativity, the potential for the development of theories that go beyond the armchair seems most promising for non-first-person, multivariate aspects of creativity – precisely the aspects that are not amenable to introspection. These include the details of and variability in the creative process, the neural and other biological bases of creativity, and larger-scale sociocultural and trans-historical patterns. Empirical study can greatly benefit, or at least most uniquely contribute to our understanding of these aspects of creativity, which would indeed constitute a real advance on the long tradition of armchair speculation.

Conclusion

The variety of current creativity theories has pluses and minuses. On the plus side, there is a pluralistic array of perspectives available, which admirably attempt to understand many aspects of this complex phenomenon, which account for current data reasonably well, and which have the potential for a great deal of integration and cross-connection. On the minus side, many theories, generally speaking, have not progressed far beyond earlier speculative claims and have often failed to spark the identification of new phenomena

and counterintuitive testable hypotheses. While it is too early to forecast the fate of theories of creativity, and the enterprise of studying creativity more generally, it seems likely that the two will rise or fall together. For any real conceptual progress to occur, existing theories must be continually constrained by more and better data and analyses, and generate new constructs for measurement and analysis in their turn.

Therapy and Counseling (Creative Process in)

C E Selby, California State University, Chico, CA, USA

© 2011 Elsevier Inc. All rights reserved.

Glossary

Creative process The act of creating, usually involving several stages or phases, that includes various dimensions of creative thinking and emotional expression or involvement.

Homospacial process Actively conceiving two or more discrete entities occupying the same space, a conception leading to the articulation of new identities.

Janusian process Actively conceiving two or more opposites or antitheses simultaneously.

Psychotherapeutic creativity The generation of relational products that result from adaptive and innovative responses

to everyday occurrences, which demonstrate newness and meaningfulness to the creator and those with whom the creator interacts.

Psychotherapeutic creative process The act of generating new and meaningful change in emotions, thoughts, and behaviors.

Relational creative products Products that involve interactions with one's self and others and include the generation of new and meaningful change in emotions, thoughts, and behaviors.

Creativity in Counseling

Creativity in counseling does not come solely from the counselor, but rather from a shared struggle of two people trying to grow. One seeks guidance in finding new ways of being in the world, while the other offers expertise and facilitates the seeker's creation of new ways of being. It is this dance between seeker and facilitator where the creative process emerges. The type of therapeutic relationship that leads to creative outcomes is a collaborative one. One in which clients are viewed as expert on their own lives and the counselor support clients by helping them to identify, access, and effectively utilize their internal resources.

Research has shown a link between the creative process and the counseling process. Both processes encourage the movement from rigid, repetitive patterns of thought and behavior and emphasize the integration of thought and emotion resulting in more dynamic and adaptive modes of thought and behavior. Many of the factors pertinent to creative production are mirrored in the counseling process. These factors include openness to experience, access to intense affect, broadly focused attention, flexibility of thought, courage, perseverance, risk-taking, and delay of gratification

The focus of this discussion is on creative process, which attempts to explain how collaboratively client and counselor work toward creative outcomes. What steps are necessary to take a client from being stuck to a newfound perspective or way of being? The research literature provides two such explanations. The first theory suggested by Albert Rothenberg emanates from the psychoanalytic and cognitive perspectives in which he suggests there are two cognitive processes, namely the janusian and homospacial processes, which lead to creative outcomes in counseling. The second theory, suggested by the author of this article, comes from the humanistic perspective offers the psychotherapeutic creative process model to explain the creative process in counseling.

The Creative Process

Before looking more closely at these two explanations of the creative process in counseling, it is important to clarify what the creative process is in broader terms before applying it to the more narrow counseling context. Wallas' four-stage model of creative process, one of the most noted models of the creative process, suggests the process steps of:

1. *preparation* – the initial sensing and exploring of a problem;
2. *incubation* – problem is not consciously pursued and unconscious mental processes are involved;
3. *illumination* – sudden flash of insight when a new idea, solution, or relationship emerges; and
4. *verification* – the incomplete product of the illumination stage is revised, refined, and corrected.

This four-stage model can be applied very effectively to the psychotherapeutic process. When a client first seeks help from a psychotherapist either he/she already has a good idea of what the problem is or looks to the therapist to help him/her to discover what the problem is. During this phase of therapy, client history and life story is explored for the purpose of gaining knowledge and understanding of the client's experience and resultant difficulty. This phase mirrors the preparation stage of Wallas' model.

The incubation stage is an ongoing part of the psychotherapeutic process. Often when a client begins therapy he/she is warned that the 'unconscious pot will be stirred' and to not be surprised if and when unexpected emotions surface. This experience of stirring the unconscious is similar to what is described during the incubation stage.

The stage of illumination mirrors those moments in psychotherapy when the client suddenly gains insight and/or understanding into his/her experience. It is often expressed as, "I never thought about it that way!," or "I think I know what to do now," or "I can't believe that I never saw that before." There is a new awareness of his/her situation that previously was not there.

Verification is demonstrated in psychotherapy when the client tries the new insight or solution on for size. Does it seem to fit? During this exploration the client and therapist tinker with revising and refining until a good fit is found. Once internal agreement is determined, the client then has the opportunity to verify how his/her solution works in the 'real world.'

A second creative process model generated by Guilford views the creative process as creative problem solving. Guilford's creative problem solving model consists of six stages:

1. input sensing, also referred to as problem identification;
2. filtering, which is the process of determining whether or not to proceed with processing;
3. processing, which involves specific answers begin to be generated;
4. production, in which convergent or divergent answers are produced;
5. evaluation, which includes answers are tested, new information obtained, new tests of problem's structure, new answers generated, new answers tested; and
6. goal resolution in which creative solution is found.

Guilford's creative problem solving model of the creative process can be applied to the counseling setting as well. Clients come to counseling with an identified problem or with the help of the therapist identify the problem. The client and therapist then collaboratively determine what information is extraneous and what is relevant. The relevant information is then processed, which can lead to new insights. These new insights are then evaluated and depending upon the results of the evaluation the new insight leads to problem resolution or the need for further informational processing and insight refinement.

While both of these models have proven useful in general discussions of creativity, they are not adequate explanations for the creative process that is inherent in the counseling process. What makes the counseling process unique is it occurs in a relational context. Two individuals work collaboratively in a counseling setting and the product of the collaborative relationship is a creative outcome for the client.

The Mutual Creative Process and Therapeutic Action

Albert Rothenberg examined intrapsychic processes involved in the act of creation. While Rothenberg contends that these processes are vital to creativity in numerous areas, he focused specifically on their use in the practice of psychotherapy. The creative process in psychotherapy begins when client and therapist can agree that the client's problems derive from patterns of living, unconscious conflicts, or life history experiences. An important part of this agreement involves the client seeing the connections between conflicts and maladaptive patterns and the symptoms and suffering for which the therapist's help is sought. Rothenberg contends that this process of acknowledgement can be quite time consuming, but necessary for the creative process to commence. He views this process as preparation and likens it to the preparations that a creative artist must engage in before

creation of art. While Rothenberg sees the client as active participant in the creative process, he views the therapist as instigator of the mutual creative process via creative activity. The client could be viewed as the actor in a play, while the therapist plays the role of director. The therapist's absorption in and love for the material of psychotherapy comes before the client's interest. It is the therapist's love and absorption that fuels the entire therapeutic transaction and it a major instigating factor in the creative process. Without this love and absorption, Rothenberg contends, the creative process could not take place. The client's motivation to participate in therapeutic creation becomes facilitated by the therapeutic interaction. Through the establishment of the therapeutic alliance, the client begins to develop a sense of worth and a feeling of ability to make changes and produce creative effects. This therapeutic interaction results in what Rothenberg refers to as the mutual creative process.

The Homospacial Process in Counseling

Rothenberg proposes that the central mechanisms of creativity include the mental operations he has labeled the homospacial and janusian process. He contends that the therapist's understanding is a generative function of the use of the homospacial and janusian processes. This understanding is a core facilitator of the creative process and is achieved via the therapist's interventions, interpretations, and overall approach and provides the platform from which the client develops insight, resolves conflict, makes choices, and develops new attributions and structures. One last condition is necessary for the creative process to occur. The client has to appreciate that the risk of change is a worthy endeavor. This appreciation is made possible when the therapist helps the client feel understood in a meaningful way and therefore can undertake the risk of engaging in the creative therapeutic process.

Rothenberg believes there are numerous ways to transmit understanding however, the homospacial and janusian processes are creative modes of transmitting understanding. The sort of understanding that Rothenberg refers to is akin to empathy. Empathy means to understand as well as to share in a manner that goes beyond having the same surface feeling. It means to understand the essence of what the client is experiencing. In the psychotherapeutic transaction, according to Rothenberg, empathy involves the homospacial process. The homospacial process consists of actively conceiving two or more images occupying the same space simultaneously. This conception leads to the articulation of new identities. The therapist activates the homospacial process by cognitively and affectively formulating multiple entities as occupying the same space. The therapist conceives his self representation together with the client in the same space. In this process, the therapist superimposes his representation of himself with his mental model of the client. For example, the therapist may conceive of himself as sitting where the client is, which would consist of a mental image, as well as mentally represented word and sound experiences he has

had in sessions with the client. All five of the senses can be involved. The mental model results from an extended association with the client, including a systematic knowledge of the client and a life time of professional experience with human suffering, conflict, and crisis. Ultimately what is created is an empathic understanding of the client's lived experience. Rothenberg views the use of the homospatial process in the service of deepened client understanding as a creative act in personal relationships. Empathy produces interpersonal knowledge where it did not previously exist. This production of new knowledge deepens the therapist's understanding, lessens anxiety levels through unearthing of unconscious material and the therapist uses this understanding in his general approach or offers it to the client who can either verify, deny, or accept it. When the formulations are effective, the client usually introduces new material or collaborates in a mutual creative process.

The Janusian Process in Counseling

The janusian process consists of actively conceiving two or more opposites or antitheses simultaneously. During the course of the creative process, opposite or antithetical ideas, concepts, or propositions are deliberately and consciously conceptualized side-by-side and/or coexisting simultaneously. These formulations are constructed in clearly logical and rational states of mind in order to produce creative effects.

The janusian process requires an intensive knowledge of the client, which is gained during empathy development and the homospatial process. This intensive knowledge enables the therapist to identify salient themes in the client's past and current feelings, thoughts, and behaviors. Antithetical content is identified and made conscious. For example, a client may describe an experience where her thoughts and actions demonstrated superiority and inferiority simultaneously. This new awareness of disparity often is experienced with feelings of surprise, sudden realization, and sometimes breakthrough. The process is responsible for the production of insight and discovery.

As previously stated, Rothenberg emphasizes the mutuality of the creative process and therapeutic action. Both therapist and client are engaged in enhancing the client's self and social worth, as well as the growth and development of the ego. The client must present with the motivation and willingness to choose new patterns of behavior, just as a creative artist chooses to create new artistic content. The therapist needs to experience the activity of psychotherapy with another as a worthy endeavor and bring to the experience absorption and love for the material of psychotherapy. Rothenberg likens the therapist's experience to that of the artist's love and fascination of the words, paints, and sounds that are used to produce literary, artistic, and musical works.

Rothenberg states that once a client realizes the possibility for change, the therapist's creative skills facilitate the process. Once the client determines what creative outcome is desired the mutual creative process becomes activated. The creative therapist can guide the client through the homospatial and janusian process thus inducing and maintaining creative engagement for the purpose of gaining new and valuable effects.

The Psychotherapeutic Creative Process Model

The psychotherapeutic creative process model shares common features with Guilford's creative problem solving model and Wallas' creative process model. The psychotherapeutic creative process model was developed in order to address the relational aspects that are unique to the therapeutic setting, which creative process models to date have failed to adequately address. This model is the result of an extensive qualitative research study in which 20 therapeutic encounters, involving at least five sessions per encounter, were analyzed for creative process variables. The result of this analysis yielded the psychotherapeutic creative process model which consists of eight stages:

1. preparation for creative therapeutic outcome – problem identification, focused attention on the problem, and problem deconstruction;
2. exploration of problem resolution – exploration of problem solving strategies and exploration of potential benefits of problem resolution;
3. processing shift toward problem resolution – cognitive, affective, behavioral, experiential, problem awareness, intention, readiness shifts, shift from external to internal process, internalization of shift, and internalization of benefits of problem resolution;
4. problem insight;
5. transformation of shift/insight into creative action;
6. implementation of problem solving strategies – successful or unsuccessful implementation of problem solving strategy;
7. actualization of creative therapeutic outcome; and
8. evaluation of new behavior, cognition, or emotion – exploration of goodness of fit, exploration of benefits of problem resolution, identification of obstacles to sustainability, and reinforcement of creative change.

While it appears that this model unfolds in a linear fashion, it is important to make clear that this is not the case. The psychotherapeutic creative process is a fluid and dynamic process, at times multiple stages will happen simultaneously, out of order, or stages frequently revisited. The linear presentation is used only because of the limitation of the medium of reporting.

Stage One – Preparation for Creative Therapeutic Outcome

The first stage of the psychotherapeutic creative process model, preparation for creative therapeutic outcome, includes the process steps of problem identification, focused attention on the problem, and problem deconstruction. In many cases the client comes to the therapeutic encounter with a good idea of what the problem is, however the therapist is able to help the client further clarify, restructure, or redefine the problem in such a way that enables the client to begin to entertain more creative solutions. Yet other clients may know that they have a problem but lack any understanding of what the problem is, thus necessitating the therapist's more active engagement in problem identification. Regardless of what level of problem identification the client possesses at the commencement of counseling, therapist and client work collaboratively to clearly identify the problem.

Once the problem is identified, therapist and client begin to focus their attention on the problem which involves conscious examination of the client's emotions, thoughts, and behaviors connected to the identified problem. This focused attention manifests in problem deconstruction. Problem deconstruction involves exploration of the problem components. The process of deconstruction yields valuable information about how the problem began, what sustains the problem, what gets in the way of the client solving the problem, what benefits are derived from engaging in the problem, what outside forces enable the continuation of the problem, and what solutions have been tried, but failed. As the client and therapist actively engage in this stage one process, the client begins to experience a sense of understanding regarding the problem.

It is important to note that filtering is a part of the psychotherapeutic creative process model. Filtering describes the decision process clients go through regarding whether to focus their attention on a problem or to set it aside and focus elsewhere. As client and therapist work toward problem identification, additional problems may come to light that are related to the problem that brought the client into counseling. An assessment must be made to determine whether or not these newly identified and related problems are relevant to the production of creative therapeutic outcomes. If the new problem is determined to be irrelevant, the conscious decision is made to set the problem aside, thus filtering out the extraneous problem. Filtering intervenes throughout all stages of the creative therapeutic process model.

Stage Two – Exploration of Problem Resolution

The second stage, exploration of problem resolution involves the exploration of problem solving strategies and potential benefits of problem resolution. Before a shift toward problem resolution occurs, it is important to identify benefits that may result when problem resolution is achieved. This exploration results in motivating the client toward change. Often the client receives unconscious benefits from maintaining the problem. During stage one, part of the problem identification process is to make conscious the benefits that come from sustaining the problem. It is equally important to provide the client with the opportunity to explore the benefits that will come with the creative therapeutic outcome.

Once the client is able to generate a list of benefits, discussion of problem solving strategies, including identification of previously unsuccessful strategies, occurs. It often proves useful to revisit these strategies, identify what may have gone wrong, explore alternative approaches to previously failed problem solving strategies. Filtering becomes important during this exploration, as some problem solving strategies might never prove successful and therefore should be filtered out. However, if client and therapist can identify the stumbling block that prevented a viable solution from being realized, develop an alternative approach, a previously failed strategy can be transformed into a viable one.

Divergent thinking, which is a kind of thinking that involves thinking in different directions for a variety of answers to questions that have many right answers, facilitates the process of problem solving strategy exploration. Rarely do life problems have only one solution. Client's are asked to suspend the internal

critic that often gets in the way of divergent thinking and encouraged to actively pursue numerous problem solving strategies.

Stage Three – Processing Shift Toward Problem Resolution

The third stage, processing shift toward problem resolution signals a qualitative shift in the creative psychotherapeutic process. During this stage the client shifts from focusing on the problem to focusing on the problem resolution. As the therapist and client collaboratively explore problem solving strategy options, the client begins to process and internalize the material generated thus far in the process. This process of internalization leads to an internal shift. A shift is defined as an internal movement, in which the newly internalized material acts as a catalyst. At this juncture a once stuck client becomes freed from the mire of the problem and is now able to begin the transformational process of creative change. There are numerous shifts that can occur. These include cognitive shift, affective shift, behavioral shift, experiential shift, problem awareness shift, intention shift, readiness shift, and shift from external to internal processing. The client is not limited to just one type of shift. Multiple shifts can occur simultaneously. Inclusive in this phase is the client internalizing the shift(s) and internalization of the benefits of problem resolution. Therapist and client actively and collaboratively dialog about the shift and this dialogue serves to validate and reinforce the shift that occurred thus facilitating internalization of the shift and the benefits of problem resolution. Filtering can occur at this point as well.

Stage Four – Problem Insight

Processing shift toward problem resolution leads to problem insight, the fourth stage of this model. Problem insight, refers to a core understanding of the nature of the problem and the necessary steps to take toward problem resolution. It is important to note that problem insight can occur at the earlier process step of exploration of problem resolution or even during the preparatory process stage. However, it was observed that in most instances, problem insight occurred following the third stage – processing shift toward problem resolution.

Stage Five – Transformation of Shift/Insight into Creative Action

During stage five, problem insight leads to the client becoming proactive in which the internalized shifts and problem insight gained during the previous two stages is transformed into creative action. Creative action takes the form of implementation of problem solving strategies collaboratively generated by the therapist and client. Creative action can take the form of therapist and client collaboratively developing an action plan to deal with the problem and the client then implements the plan in the real world. Creative action can also occur organically without explicit plan formulation. Once problem insight occurs, the client when faced with the same problem in the real world will automatically respond in a new way. For example, once a client is able to identify and label the problem as difficulty setting limits with others readily identifies this problem when encountering it again automatically, without having articulated a plan

with the therapist, responds in a new way, using new thoughts and behaviors that are adaptive. Problem insight results in automatic creative action on the part of the client.

Stage Six – Implementation of Problem Solving Strategies

Stage six involves the successful or unsuccessful implementation of problem solving strategies. If a problem solving strategy is implemented successfully, actualization of creative therapeutic outcome occurs. Creative therapeutic outcome is manifested with behavioral, cognitive, and/or affective change. If unsuccessful implementation of problem solving strategies occurs, the therapist and client then loop back to any of the previous stages – preparation for creative therapeutic outcome, exploration of problem resolution, or processing shift toward problem resolution – for reworking and refinement of the problem and possible resolutions.

Stage Seven – Actualization of Creative Therapeutic Outcome

This stage involves the actualization of client creative change in which new behaviors, cognitions, and/or emotions become a reality. The client exhibits either new behaviors that are functional and adaptive; thoughts that enable the client to rationally and adaptively deal with challenges; or emotional reactivity that is appropriate and proportional. The client has effectively navigated the necessary process steps to achieve a creative therapeutic outcome.

Stage Eight – Evaluation of New Behavior, Cognition, or Emotion

This stage involves the exploration of goodness of fit of new behavior, cognition, or emotion, exploration of benefits of problem resolution, identification of obstacles to sustainability, and reinforcement of client creative change. Goodness of fit involves the determination of the suitability of the creative therapeutic change to the client's life. Whenever change occurs, there is a chance that initially the client may express awkwardness, discomfort, or feeling of incompetency. It is important during this stage for the therapist to help the client navigate the uncertainty that comes with newness. The challenge is to discern between the discomfort that comes with adjustment to change and a solution

that is a poor fit for the client's life. If the determination is made that adjustment difficulty is the source of discomfort, then the therapist provides support and guidance to enable the client to sustain the change until adjustment is achieved. However, if goodness of fit is the problem, then it is necessary to return to stage three for further processing of problem resolution.

Once the creative therapeutic outcome has become actualized, exploration of benefits of problem resolution is key to sustain client creative change. Benefit identification acts to reinforce problem resolution and resultant creative therapeutic outcome, thereby increasing the likelihood that the client will continue on the path of resolution and avoid returning to maladaptive behaviors, thoughts, and/or emotions. Equally important is identification of obstacles to sustainability. When clients experience the success of problem resolution, it is easy to focus only on the exhilaration and relief of being free from the problem. It is important to inoculate clients by exploring obstacles to sustainability of creative change and generating strategies to deal with potential obstacles. Ultimately, exploring benefits and obstacles serve to validate and reinforce creative client change.

Glossary

Creativity complex The notion that creativity is a syndrome and is multifaceted.

Future problem solving A program in which children practice solving realistic, open-ended problems.

Impulsive cognitive style The tendency to work quickly. (cf. Reflective Cognitive Style).

Incubation Time away from a problem – at least consciously. The person may continue to work on a preconscious level, with an ‘ah-ha!’ occurring when a solution is found.

Let it happen strategies Tactics that involve leaving the problem for a time, allowing incubation and the like to contribute to the problem solving effort.

Old age style Intentional changes made by artists, often in the seventh or eighth decades of their lives.

Reflective cognitive style The tendency to take one’s time when working.

Stage model of creative thinking Proposed by Graham Wallas in 1926, with preparation, incubation, illumination, and verification stages. Time is absolutely required by the second stage and probably necessary for the first and fourth as well.

Ten-year rule Data suggest that ten years of work, or 10 000 h, need to be invested into a domain for expertise to develop.

Time in Personal Processes

Creativity is often defined as a syndrome or complex, the premise being that it is multifaceted. Not surprisingly, then, several different aspects of creative behavior have been connected with time.

Time has, for example, been tied to the cognitive bases of creative thinking. Creative thinking has been defined in associative terms, with the prediction that individuals tend to generate problem solutions in concatenated chains of associations. The first few associations are usually rote, obvious, and unoriginal, but the later and more remote associations become increasingly original. Time is relevant to the associative basis of creative thinking because it takes time for an individual to move through the obvious ideas to find the remote associates. These predictions about remote ideas being original have been repeatedly confirmed. One of the most commonly cited models of the creative process was proposed in 1926 by Graham Wallas, indicating that problem solving consisted of the four stages of preparation, incubation, illumination, and verification. Incubation implies that some time must elapse. During that time the individual is not consciously working on the problem – but is working on the problem on a preconscious level. The preconscious often succeeds in solving the problem because it encounters fewer constraints than the conscious (and logical) efforts. In 1971 J. P. Guilford claimed that Wallas’ description of the stages is primarily designed for problems of great importance – problems that demand a long period of work. Guilford proposed that Wallas’ steps are involved in solving ordinary everyday problems, but they are compressed.

The need for incubation (and time) was also noted by Sidney Parnes. He distinguished between ‘make it happen’ and ‘let it happen’ strategies for creative problem solving. The former are exemplified by very intentional and systematic tactics, such as working backward (starting with the solution and

trying to work back toward the initial state) or turning a problem on its head. The latter are exemplified by things like taking a walk or turning to another task; the assumption is that incubation will occur. This in turn assumes that time (for incubation or at least thinking and processing) is useful.

Incubation is often preceded by the state of fixation. That may lead to an impasse, which is an affective result of the lack of progress. The affect is characterized by negative emotions emerging and the person feeling stuck. He or she may quit consciously considering the problem. This is the time that is required for incubation. In other words the time that is not predated by fixation cannot be regarded as incubation.

Flora Beeftink, Wendelien van Eerde, and Christel G. Rutte examined the differences between interruptions and breaks (often a matter of choice) on impasses and insights. In interruption condition, participants are forced to switch tasks at a predetermined moment; in breaks they could switch tasks when they chose to do so. Both breaks and interruptions contributed to impasses, but interruptions did not contribute to solving more insight problems unlike breaks.

Time may be required by one of the most general of the tactics used for creative problem solving: changing one’s perspective. Changes of perspective can break a mental set or routine and allow creative insight. Perspectives are often changed literally, by finding another viewpoint or way to represent the problem. A new perspective can also be found simply by taking time away from the problem. Every writer knows that one’s own work can be difficult to edit if immersed in it. But if you take time away, editorial work is easier. We become more objective and sensitive to details. The same is true in other areas, where time provides perspective. Unlike incubation, where the preconscious continues to work on the problem, here it is actual and complete time away from the task.

Howard Gruber described how many seemingly instantaneous and sudden insights are actually protracted and spread out

through time. He suggested that insight is *not* a sudden process. Each insight supposedly has a developmental history. According to Gruber, mastery of creativity requires repeated practice which implies that a great deal of time must be available and is then invested. For this reason, hard work and repetition are important for creativity. He called this process *constructive repetition* and defined it as a conscious repetition and revision of a concept to establish its best form for a creative product. As an illustration, Beethoven revised his works 20 or 30 times before he decided the acceptable form of the piece. This is contrary to the popular conception of insights as sudden. The illumination may seem sudden but what led up to it may require that time be invested.

The creative individual may rely on certain cognitive capacities and abilities, such as those mentioned above, when working, but he or she must also be interested in using those capacities or abilities. This interest is described as 'intrinsic motivation.' If intrinsically motivated, the individual will invest time and effort into a task, problem, or domain. Importantly, an event may increase or decrease intrinsic motivation depending on its meaning to the recipient. According to cognitive evaluation theory, if an event is perceived as a pressure to reach a particular goal (as controlling), intrinsic motivation is undermined. On the other hand, if an event is perceived as an internal locus of causality for behavior (as informational rather than controlling), it enhances intrinsic motivation. Therefore, perception of time limits counts. According to Richard Koestner, in a creative activity, people who have no-limit or informational limit spent more free choice time, an indication of high intrinsic motivation, than people who have controlling limits. When it comes to products, Koestner found that the no-limit condition was superior to controlling condition in terms of creativity ratings. Higher technical quality of the products was evident in informational limit condition than the controlling condition.

Timed Tests

Creative potential is often estimated with special tasks or tests. When these tasks or tests are administered, special instructions must be given. Otherwise respondents tend to view the tasks as similar to the academic tests most of us have experienced, and when they do that, creativity is a low priority. On academic tests it is important to find the correct answer, spell it correctly, and earn a high grade. When generating original responses to an open-ended task, there may be no correct answer. There may be many appropriate answers, some of which are original and some of which are not, but there is no one correct answer.

For originality on the part of the respondents, grades, conventional answers, and time must be deemphasized in the task instructions. Instead of imposing a time limit, examiners should allow the individual to make the pertinent decisions about investing time and effort for him- or herself. By allowing individuals to decide for themselves how much or little time to allocate to the task, the distinctiveness of divergent thinking (and originality) from convergent thinking is maximized. Performance on the test is determined by the respondent's intrinsic motivation, which often facilitates creative thinking. The flexible time limits also allow the individual to find remote associates and perhaps incubate.

There is a common criticism of tests, including tests of creativity, which is the most tenable if they are timed. In the natural environment, creative work may rarely have a timed component, at least one that is similar to that used with tests. If we wish to predict real world creative work, the predictor should require the same tendencies as the criterion behavior. This implies that if creative work in the natural environment is rarely timed, so too should the assessment of creative potential be untimed. The rebuttal to this view is that tests are merely estimates of the potential for real-world creative activity, and that they must have constraints on them to allow them to be used in research and educational settings.

Culture

Clearly, cultural norms and expectations can limit an individual's creativity. He or she may not think of some possible solutions to a problem because they are taboo within the present culture. Adults in the United States, for instance, may not consider humor or play as contributions to creative work. Work is supposed to be serious rather than fun. Similarly, in the United States there is often pressure to work quickly and to be productive. It may not be easy to tolerate incubation and to appreciate the value of 'let it happen' tactics. Time is a valuable commodity and incubation may be seen as a waste of time. One step toward avoiding cultural blocks, like the prejudice against humor, play, and incubation, is simply recognizing that they are imposed by culture rather than absolutes.

Expertise as Time Invested

Some domains may require years to develop expertise. Various investigators have suggested that ten years (or 10 000 hours) need to be invested in a particular domain for expertise to develop. To the degree that expertise is necessary for creative work, this may indeed be a requisite investment. In some areas, expertise may be easier to obtain and require less temporal investment. (These may be domains which depend the least on familiarity with a body of factual information.) What may be surprising is that expertise can sometimes actually inhibit creative insight. Experts sometimes make assumptions that preclude original thinking. They sometimes have invested so much into their area of expertise that they are resistant to considering alternatives. Dean Simonton has described other requisites for high-level achievement. He pointed to three tendencies of eminent persons: they start their careers early, they are productive, and they live a long time. Time is involved in each of these. Time is also implied by economic and investment theories of creativity. These use the parallel idea that creative persons tend to invest a great deal into their work. Investments may be temporal. This may sound like another way of saying that expertise takes time to develop, but here it is more that the person concentrates, and frequently, on the task at hand or field of choice. It is possible that investments can work against creative success. In this sense the psychoeconomic theories of creativity support the idea that expertise can sometimes inhibit original thinking. Theoretically, an individual who has invested a great deal in one idea or line of thinking

would experience a 'depreciation' of his or her knowledge if new lines of thought supplanted the old, and this may lead them to resist new lines of thought.

Developmental Trends and Rates

Time is often used as a categorical independent variable. This is exemplified in longitudinal studies, where various follow-up assessments are conducted after a particular interval has elapsed. Louis Terman conducted the most famous longitudinal study, though his (gifted) subjects were selected based on IQ and traditional intelligence. Time is also implied by other developmental research, where changes depend on maturation and the passing of time. Some longitudinal studies have found discontinuities and changes that would not be apparent with any other research design. Other studies have found continuities. Consider Robert Albert's longitudinal study of exceptionally gifted boys. This investigation has been in progress for approximately two decades. One of the key findings of a recent follow-up assessment was that certain subjects were 'cross overs.' By this Albert meant that subjects had changed their interest from one domain to another. The change was apparent only because the longitudinal research design allowed a comparison of career interests and general preferences at several points in time. There are also continuities that can be uncovered only with longitudinal research designs. Mihalyi Csikszentmihalyi and Jacob Getzels, for instance, found that art students who invested more time in the preparation of the subject matter were more original – even 18 years later.

The domain specificity of the creativity peak was also highlighted by Harvey C. Lehman, and later by Dean K. Simonton, in research on exceptional achievement. This line of work suggests that philosophers and social scientists need a longer time to master products than poets and mathematicians. Usually poets and mathematicians peak in their twenties, but social scientists peak in their thirties or forties. Development is a lifelong process, and certain discontinuities appear late in life. Some may facilitate creative work. Many older artists are, for example, less concerned with criticism than they were when younger, and this can allow them to focus on authentic self expression and experiment in their work. Martin Lindauer and others have found that many of the most creative artists intentionally changed their style as they got older – often in the seventh or eighth decades of their lives. These changes to an 'old age style' may have contributed to the artists maintaining a fresh perspective and creative hand. Such changes and perspectives assume that time must pass – the old age style is simply not found in younger individuals. Elapsed time is sometimes not the concern. Time can also be used to calculate other indices of development, such as 'rate.' Rate is the standardization of occurrence as a function of time. Of relevance here are rates of development and rates of creative productivity that reflect individual differences. There is, for instance, evidence that various facets of thought develop at different rates. J. P. Guilford described in detail different kinds of ideational flexibility and how they mature and fail at different rates. Using Guilford's own terms, the 'flexibility of classes' is lost at a different rate than is the 'flexibility of transformations.' Support for this view has been provided by the research on divergent thinking.

Attributions of Creativity and Time in Interpersonal Processes

Time is required for some of the social, interpersonal processes that contribute to creative work or are involved in our judgment of it. Many researchers have argued that the attribution of creative ability is most accurate only after a long period has elapsed. That ostensibly gives the judges a better perspective. The need for a long-term perspective is evidenced by the changes that sometimes occur in reputations. Rembrandt, for example, was not the most famous artist of his time, but he is now one of the best known from his era. The work of Gregor Mendel was largely overlooked for 50 years.

An issue arises when eminence is defined in terms of social attributions. This brings into question of a creative genius being ahead of his or her time. If creative geniuses are ahead of their time, their genius might not be recognized. Records might not be kept of his or her work and no attention would be given to it. The assumption is that the reputation of creative exceptionalism emerges because of the social and cultural context. This may occur in two ways. The product may not receive much recognition during the creator's lifetime; or the exceptionalism may be recognized during the genius' lifetime, but forgotten after his or her death. In fact, necessary resources might not be allocated to the individual because of the lack of appreciation. In that light the creativity might never develop to the level necessary for exceptional achievement. A second interpersonal issue involves the possibility that immediate temporal constraints can undermine creative work. This was implied earlier, in the discussion of task instructions for assessments of creative potential. It was further intimated by the attributional process that some apply to judgments of creative performance. It can be explained by referring back to the economic theory of creativity, because there time was defined as a resource. Time can be invested in one's training or work. This is an interpersonal dynamic when other persons (e.g., parents, teachers, or supervisors) decide how much time we can invest in our training or work.

Time as Personal Construct

The research above, noting the inhibitive effects of time constraints, should not be taken to suggest that everyone will be disturbed by deadlines. Recall here that according to cognitive evaluation theory the influence of limits is only likely when they are perceived as pressure by the person. This is a kind of subjectivity of time. Along the same lines time may be conceived as occurring in routines and schedules, and these could easily be perceived as boring or repetitive. As such they may make it difficult to maintain one's creative efforts.

If routines are imposed by others, they tend to hinder creativity because they are a kind of pressure. Yet according to Mihalyi Csikszentmihalyi, not all routines harm creativity. Some persons work best under pressure. Moreover, time is a function of subjective interpretations, and different people will interpret time periods differently. The subjectivity of time, and the relationship between that interpretive tendency and creativity, is implied by research on 'flow.' Flow is characterized by a loss of self, and a loss of the awareness of time's passing.

The subjectivity of time and a second connection to creativity is suggested by the ability of certain creative persons to look beyond the present. This tendency is epitomized in the 'future problem solving' educational program and in the 'proactive creative work' of some creative persons. Proactive creative efforts may allow us to avoid problems, or solve them when they are minor, rather than solving them or dealing with them when they are so large as to be unmanageable. One part of the subjectivity of time can be explained by 'cognitive style.' Impulsivity and reflective cognitive styles have, for instance, been isolated, and they differ in terms of how much time is required or used by the individual. Perhaps one individual uses a great deal of time because they are not really aware of its passing. Indeed, that is one of the basic premises of the concept of flow. To the extent that creative insights are often protracted, impulsivity might decrease the likelihood of creative work.

Conclusions

Time is thus relevant to several cognitive and metacognitive processes that might be involved in some creative thinking. It is related to incubation and necessary for the remote associates that tend to provide original ideas. Time can be used strategically, in 'let it happen' tactics, and it may be indicative of investments and intrinsic motivations of creative persons. It should be explicitly deemphasized when using tests of creative potential. The cultural basis of time should be acknowledged, even as specifically associated with creative work, as should the value of time as a resource in most organizational and educational settings. Time is used in areas of creativity research in addition to what is reviewed in the present article. Gudmund Smith, for example, varies the exposure time in his Creative Functioning tests, and Norbert Jausovec examined heart rates

as related to stages in the creative process. The relevance of time is widely recognized and even more varied than the present overview might suggest. Very likely, most or even all of the ways that time influences creative behavior should be qualified. After all, virtually all other influences on creativity show optimal levels. Divergent thinking, for example, often supports creative problem solving, but only up to a point. You can be too divergent (and never bring an idea down to earth to make it useful). You can also be too independent, too conventional, too intrinsically motivated. Again, it may be that all influences on creativity are most effective at an optimal rather than extreme level. Time, then, may also have optima. Just to name one example, incubation may be a good thing for creative thinking, but perhaps only for a period of time and certainly not *ad infinitum*. The same optimization may apply to all temporal influences and correlates.

HENRI DE TOULOUSE LAUTREC's paintings and prints are linked in spirit and draughtsmanship to the work of artists such as Daumier and Goya. Lautrec's acute rendering of gesture and movement, combined with the fluent vigor with which he disposed of line and color, ensures him a place among great 19th-century graphic artists. As early as 1900, Picasso, on arriving in Paris, paid homage to Lautrec by producing several paintings in Lautrec's style. Lautrec's artistic successors, among them Expressionists such as Beckmann and George Grosz, took a few pages from Lautrec's own book in their scathing portrayals of decadent German city life. More generally, Lautrec's mature style, in which he handled his media roughly and showed small concern for the conventions of Academic painting, makes him a precursor of Modernist painters. In the spirit of these painters, he treated the medium and the technique (i.e., oil painting and lithography) in such a way that the viewer could not evade the artifice of the process and the materials.

Henri de Toulouse-Lautrec, self-portrait c. 1882–1883 from Musée Toulouse-Lautrec, Albi. Used with permission from Giraudon/Art Resource, NY.

Background

Born into an aristocratic family, Lautrec was afflicted with a glandular disorder that permanently stunted his growth. Yet, even as a sickly child he was noted for his sense of humor and for his intense involvement in the social and visual aspects of life. It was in his large and close-knit family that he acquired amateur drawing skills. As a child he loved to sketch animals, especially equestrian figures and carriages. By his late teens he was taking informal art lessons with a deaf-mute friend, the professional painter of horses Renee Princeteau. Noting the boy's talent, Princeteau advised Lautrec to start taking his art lessons in Paris.

Lautrec studied successively in the workshops of two conservative Parisian painters, Bonnat and Cormon. Even though he was pleasurably challenged by the grind of drawing from plaster casts and nudes, Lautrec never distinguished himself as an academic artist. However, by virtue of living in Paris, Lautrec was exposed to formative cultural influences: the paintings of the Impressionists and Degas (whom he especially admired), Japanese prints, and the disreputable nightlife of Montmartre. It was the habitués and performers in the clubs, theaters, and brothels who became his subject matter. Between 1885 and 1896 he produced most of the oil paintings, lithographs, and posters for which he is famous. The first public successes came with his advertisements for various Montmartre dance halls and “boites a chanson.” He made memorable posters of key figures in the nightclub district, such as the balladeer Aristide Bruant and the performers Yvette Guilbert, La Goulou, and Valentin the Boneless. Critics say that Lautrec created a definitive vision of fin-de-siècle Paris, in much the same way that Baudelaire created a verbal description of a slightly earlier Paris. (See [Figure 1](#).)

In 1897 Lautrec confirmed his notorious reputation by publishing a collection of lithographs titled *Elles*. These were based on studies that he had made while living in a brothel. Between 1880 and 1900 he received commissions for advertisements and for illustrations as well as selling his works in a number of galleries in Paris and elsewhere in Europe. His mother supported him financially and emotionally throughout most of his life and was with him when he died in 1901 at the family estate. Relations with his father remained strained up to the end. Alphonse the Count had little respect for his son's “audacious scribbles” (as he called them) and was initially opposed to any posthumous showings of Lautrec's works.

Methodological Notes: The Systems View Of Creativity

Some social psychologists wisely advocate a systems approach to the study of creative individuals. These psychologists observe that in addition to intellectual gifts of one sort or another, social and historical circumstances must be propitious for individuals to achieve creative eminence. To put it more simply, if creative individuals are to emerge, they need to be present at a time and place when their special abilities are in demand. Thus, a systems approach to the study of creative people requires the researcher to go beyond a focus on the

Figure 1 Henri de Toulouse-Lautrec, French, 1864–1901, *At the Moulin Rouge*, oil on canvas, 1893–1895, 123 × 141 cm, Helen Birch Bartlett Memorial Collection, 1928.610. Photograph © 1998, The Art Institute of Chicago. All rights reserved. Used with permission.

special qualities of the creator and to include a consideration of the intellectual domain that this person has mastered and the social organization of the field in which the person's work is recognized. For this reason, the discussion of Lautrec that follows suggests both endogenous factors and exogenous factors.

The endogenous aspects of his creative activity are those associated with the gifts and afflictions with which he was born. The exogenous features of Lautrec's life include factors such as the happy accident of his birth into a loving and well-to-do family and the historical fact that Lautrec began to produce art at a time when the French Academy of Art was losing its grip on the French art world. What emerges from the discussion that follows is a sketch of his special traits, the luck, the misfortune, and the social and historical circumstances that, taken as a whole, contributed to his emergence as a significant artist.

When we look at Lautrec's life, we can identify several key factors: (a) his precocious gifts as observer and draughtsman; (b) thematic, technical, and emotional continuities between childhood and adult art; (c) the crucial role of emotional and financial support offered by his family; (d) Lautrec's persona as an artist; and (e) the impact of class and historical setting.

Lautrec's Precocious Gift for Sure and Vital Line and His Eye for Physical Gesture and Expression

The record of Lautrec's juvenile artistic activity suggests that he fits the profile for childhood giftedness. According to Winner gifted children possess three key traits: (a) precocious ability in a given discipline or area of knowledge; (b) an intense desire to master a given medium or skill; and (c) the drive to solve problems in their own way, rather than using formulas provided by others. In all respects young Lautrec was a typically gifted child.

Precocious drawing ability

Lautrec's drawings from a young age demonstrate the quality of his rendering skills and the rapidity with which he acquired them. Lautrec's graphic profile (based on his juvenile drawings and paintings) shows that he was a prolific and accomplished draughtsman. In this respect he is like many other visually gifted children who pour out huge quantities of drawings during their early years. It is evident that he possessed a high degree of visuospatial intelligence. About 2500 of Lautrec's drawings and paintings exist that date from ages 6 to 17. (These drawings were saved for purely sentimental reasons by his doting mother and relatives.)

As expected, not all of the drawings are phenomenally accomplished, but a significant number are noteworthy. In some of his earliest drawings of carriages and horses, he demonstrated an unusual mastery of line and movement. His use of sweeping contours to suggest the body of a horse in motion is unusual in the work of a 6-year-old child. As in the drawings of other, less gifted children, we find a mix of accomplished and less skilled drawing performance all in the same picture. Lautrec's sketches of his favorite subject matter—horses—are more accomplished than his renderings of birds—a less favored topic.

An examination of the collected juvenile work reveals the presence of multiple graphic streams. These streams indicate the early emergence of what Gruber and Davis call "networks of enterprises"—a hallmark of the way that creative individuals work. Among Lautrec's juvenile images one finds life studies, caricatures / broadsides, illustrations, and a visual vocabulary taken from both academic and popular art. Several of these varied approaches can also be found, all in the same work, in some of his adult creations. For example, in *Le Cirque Fernando* (see Figure 2), the sinister ringmaster is flat and cartoonlike, whereas the horse and equestrienne are rendered in a much more plastic manner.

Delight in mastery

As a child, Lautrec showed an intense desire to master new problems and to meet representational challenges. The sketches on the margins of his school notebooks and textbooks give us a glimpse of a child struggling successfully with all aspects of rendering: mastery of spatial depth, articulation of limbs, fall of clothing, and the interaction of figures with each other.

Although Lautrec's family encouraged him to draw and paint as a form of gentlemanly diversion, he did not receive formal lessons until middle adolescence. Yet sketches from his childhood reveal that he set himself all sorts of impromptu lessons and problems. In one case, we find a set of sketches of what are probably toy circus acrobats perched on the tops of several pages in his French Latin dictionary. (In his letters from the period he mentions his fascination with an American toy circus.) On each of five pages he shows a different tumbler or acrobat engaged in gymnastics on a pole. The ink sketches look as though they were all executed in one sitting and demonstrate how well his pen kept up with his prolific imagination. These sorts of drawings are typical of the material from this period and show that he actively pursued visual ideas and schooled himself in drawing. Later in his artistic apprenticeship in Paris, he wrote to his mother that he sorely missed the more demanding artistic standards set by an earlier painting

Figure 2 Henri de Toulouse-Lautrec, French, 1864–1901, *Equestrienne (At the Circus Fernando)*, oil on canvas, 1887–1888, 100.3 × 161.3 cm, Joseph Winterbotham Collection, 1925.523. Photograph © 1998, The Art Institute of Chicago. All rights reserved. Used with permission.

teacher (Bonnat). So even when it came to the drudgery of drawing from casts and nudes, Lautrec enjoyed the technical challenge demonstrating his delight in mastery.

Marching to the beat of a different drummer

As a child and adolescent, Lautrec curbed whatever impulses he may have had to arrive at his own solutions to artistic problems. He was not consciously iconoclastic, although one of his fellow students in the Paris studio school noted that even his life studies tended to be more expressive and eccentric than was quite acceptable. However, it was not until he was on the threshold of maturity that his original artistic tendencies showed themselves. Winner observed that in many instances gifted children do not go on to make significant contributions to the field in which they show such early promise. But, as we know, Lautrec's unusual childhood performance did bear fruit.

Three Continuities between Childhood and Adult Art

Rapid and characterful sketches

Lautrec's early drawings of animals sometimes suffer from an understandable lack of anatomical knowledge. But what they lack in this area they more than make up for in terms of emotional power. In his childhood and adolescent studies of animal expression and motion, Lautrec was developing skills that he was to use throughout his career. Some critics feel that above all, it is this capacity to identify the essential features of expression and gesture that makes Lautrec's images so memorable. Hughes says:

He would not generalize; every figure acquires a specific energy, and each countenance is its own face, not merely a mask of passion or a symbol of social role. A little bareback rider's squinched up face above the massive churning crupper of a stallion in the *Cirque Fernando*, 1887–'88; the Cyrano nose and signature black gloves of Yvette Guilbert. . . these images live on as obdurately as the traits of Dickens' characters.

In fact, one can identify some of the sketches that Lautrec made in his schoolbooks and textbooks that prefigure the

powerful renderings that were to come from his mature hand one or two decades later. Two examples illustrate this. On page 55 of a school notebook (dated 1875–1880), there is a sketch of a heavily muscled horse with an arched neck. In one of his first mature canvasses, *Le Cirque Fernando* (1888), we find the same horse (see **Figure 2**). The rear quarters are slightly below eye level, but we can still see the broad back and the equestrienne. Carefully observed anatomy and the characteristically low viewing angle are already present in the schoolboy sketch made 10 to 15 years earlier. Above all, Lautrec's energetic line is plainly there, defining both incarnations of the horse.

An equally compelling instance of the adult use of childhood experimentation with an expressive linear sketch can be found on page 552 of Lautrec's copy of his French Latin dictionary. There we find a drawing of a face made around 1878. The woman is rendered in a few sure lines and the portrait is noticeable for its closed eyes, wide cheekbones, thin lips, flaring nostrils, and high forehead. Her expression is supercilious. In Lautrec's lithograph of Yvette Guilbert, *Linger Longer Lou* (1898), we find a similar effect created by the same means: inflected lines that suggest thin lips, high cheekbones, closed eyes, and flared nostrils. In some of Lautrec's other studies of Yvette Guilbert we find the same blueprint, sketched in late childhood on the back page of his dictionary. It is as though he learned how to construct a particular expression, which then became part of his stock in trade.

It is plain from an examination of Lautrec's juvenile sketches that his gift for telling characterization based on a masterful control of line was first developed as a schoolboy and that this capacity informed his adult work. It is worth noting that the relationship between Lautrec's childhood work and his mature oeuvre bears out Gardner's 10-year rule. Gardner's idea is that with many creative individuals it takes a decade between the emergence of a novel idea and its mature expression. This is certainly the case with the two examples cited.

A strong affinity for narrative illustration: lautrec's seminal collaboration with bruant

Another connection between childhood drawings and adult work is Lautrec's lifelong penchant for narrative and humorous

commentary. From his earliest days, Lautrec was a student of the social scene and an inveterate satirist. Forced by circumstances to watch his able-bodied cousins play, he early developed the habit of observation. When he was convalescing at a health spa in the mountains, far away from his cousins, he amused his absent family by sending comic verbal and visual depictions of the hapless guests. A crisis in his uncle's vineyards became the occasion for an illustrated journal outlining the battle waged and won against the vine blight. At the age of 17 Lautrec collaborated with his schoolmate Etienne Devismes in illustrating a maudlin story about an old cavalry mare named Cocotte. Still later, in Paris, it was Lautrec's interest in illustration that led him into his first artistically productive (and commercial) collaboration with Aristide Bruant, café owner and balladeer.

Lautrec's affinity for illustration resulted in the development of important stylistic changes in his work. According to Murray, Lautrec's first serious collaboration with Bruant the nightclub singer led the artist to find a visual approach that was for the first time identifiably his own. To create the illustrations, the artist studied popular newspaper drawings. These images supplied him with a repertoire of genre scenes, and some of these were to become Lautrec's stock-in-trade. Murray also suggests that the collaboration with Bruant had a strong influence not only on Lautrec's subject matter but also on the manner in which he chose to depict the singer's lurid stories. Bruant's musical delivery was harsh and unrefined. Some of the same coarseness is reflected in Lautrec's choice of cheap materials (cardboard) and his deliberate lack of technical polish.

Thus, Lautrec's business association with Bruant was a truly formative relationship, resulting in his choice of what we now know as Lautrec's typical subject matter and the development of his typical visual treatment. As a result of Lautrec's working relationship with Bruant, his art began to move in the direction of what we, from our perspective, see as a proto-Modern aesthetic.

Emotional distance from his subject matter

There is an important emotional continuity between Lautrec's childhood and adult work. This is the consistent psychic distance that he maintained between himself and his subjects. He was doubly distanced from his subjects. This double distance was due to his painful awareness of his physical deformity (something he despairs of in his letters to his family) as well as to his cherished identity as a nobleman. As a child he was fascinated by animals of all sorts. About 40% of the existing drawings that he rendered between the ages of 6 and 19 are of animals alone or of animals with people. As an adult he was still "at the zoo," but this time he was a disabled nobleman looking at the underclass of Montmartre. It is no coincidence that a couple of critics have noted that Lautrec casts a telling but cold eye on his human subjects. Lautrec himself refers to his prostitute models lolling about "like animals."

It is probably due to his strong identification as an aristocrat that we look in vain to his studies of marginal people for a progressive social commentary. Some images are quite telling. For instance, the highly accomplished drawing of an African man dancing in a bar for the amusement of its clients

(*Chocolate Dansant*) carries no special critique of racism. Similarly, in the Dreyfuss affair, Lautrec took no sides at all. And although he illustrated the work of Jewish authors, he had no qualms about contributing illustrations to antisemitic novels as well. Social issues per se did not interest him. What concerned him was solving the formal and technical problems of portraying the inhabitants of the demimonde. Lacking both an aesthetic and a social agenda, he was a voluptuary. If he had a grand project at all, it was to be the engineer of his own psychological survival—and his art along with his gregarious activities was the principal means he used to achieve this end.

The Crucial Role of Emotional and Financial Support Offered by His Family

Theorists have written about the importance of the family as a support system for exceptionally able individuals. It is a common error to believe that genius will out, and that people with exceptional abilities do not need support or instruction. Quite the contrary—children with special abilities require the nurturance and intense support of parents and family. We can see the effect of such support in the case of Lautrec. Although his mother never had much appreciation for his art, she was a selfless and devoted parent. She took charge of his health problems and throughout his life made sure that Lautrec's material needs were supplied. Lautrec's father was another matter. Once it became clear that Henri would never ride to hounds nor look like a gentleman on or off a horse, Alphonse pretty much gave up on his son. There were periods during Lautrec's childhood that his father was not there for almost a year. On the other hand, the rest of the large family was close-knit and took delight in Lautrec's wit and imagination. This family became Lautrec's first audience. And it was the family (particularly his Uncle Charles) that encouraged him in his art.

However, the relationship between Lautrec and his family was by no means idyllic. Throughout his life, Lautrec was very dependent on his mother, and when she grew upset with his drinking and carousing, she abruptly left Paris without informing him. This sudden departure precipitated a psychological episode that ended with Lautrec briefly staying in an asylum. The incident reveals the difficulties that both mother and son experienced in dealing with each other. At the end of his days, Lautrec turned to his mother, who nursed him through his final illness.

Lautrec also may have considered commercial business to be a mark of independence. Even though there were no pressing financial reasons, Lautrec was fascinated by the idea of selling his work and of engaging in the *petit bourgeois* activity of producing posters and illustrations for trade. The notion of their son as a tradesman must have been at least as unpleasant to his patrician family as the certain knowledge that he was awash in the fleshpots of Paris. But Lautrec pursued his business ventures in Paris, perhaps for several reasons. First, he was not getting anywhere in the academic art world. He did not achieve success in his academic art exams. Thus he was forced to seek another audience for his artwork. Second, the prospect of earning money must have been emblematic of a certain degree of independence. Last, it may have pleased him to tweak his patrician family's sensibilities by threatening to succeed as a businessman.

Lautrec's Persona as an Artist

In addition to refining a style and subject matter that was truly Modern in spirit and attack, Lautrec contributed another element to the attributes of the modern artist. He actively constructed a flamboyant private and public life. With his outrageous antics, his notorious drinking and dressing up, he contributed to the stereotype of the artist as a public figure, the bohemian and tormented genius. Like his father, Lautrec was flamboyant. As Frey points out, both father and son liked to show off (in French *S'afficher*). Lautrec was of course best known for his *affiches*—his posters. The son elaborated his marginality by stressing his physical deformity through wearing odd costumes and by deliberately associating in public with his very tall cousin.

He behaved in ways that were calculated to shock and surprise the bourgeoisie (e.g., he spent months painting in a bordello). The prototypical Modern artist (and the Romantic artist before him) was always understood as an obsessed and intense person, one whose behavior was always close to the edge of—and sometimes beyond—the bounds of social convention. One critic has recently suggested that there is a strong parallel between Lautrec's artistic persona, with his entourage of Parisian followers and freeloaders, and the pop artist Andy Warhol's penchant for strikingly odd personal presentation and his retinue of camp followers.

The Impact of Class and Historical Setting

This article has already examined the factors that may have charged Lautrec's business venture with psychological meaning. There is little doubt that Lautrec sought recognition from his peers, and when it was not forthcoming from the academic world (one of his studio teachers informed him that his drawings were "atrocious"), Lautrec turned to the world of commercial art. As we know, he achieved a high level of success in this setting, for his posters were so sought after that on some occasions Parisians would rip them down to keep as soon as they were displayed. At the same time that Lautrec was having his public successes, the structure of the French art establishment was changing.

Standards for "good art" were in flux and artists organized themselves into alternative settings for the display and sale of work that met with official displeasure. The famous Salon de Refusees (an exhibition by artists of works that had been refused a showing in the French Academy) is an example of the avant-garde community taking matters into its own hands. But, during his lifetime, it was Lautrec's public work and his popular illustrations that helped establish his name. Yet the forces that were then eroding the power of the French academy

contributed to the rise of artistic Modernism, and it was the ascendancy of this aesthetic paradigm that assured Lautrec of his immense influence.

Summary

Several key features contributed to Lautrec's emergence as an artist of note: (a) his early and sustained fascination with a medium (drawing) for which he showed a precocious affinity; (b) a precocious capacity for close observation and rendering of animal movement and expression, which laid the groundwork for his studies of people; (c) the defining experience of being an intelligent and engaging child, who was often forced to observe the world from the sidelines (this sense of alienation was replaced in adulthood with a painful self-awareness of permanent physical abnormality and of aristocratic class identification); (d) a lifelong delight in entertaining others through dressing up and verbal and visual invention; (e) the emotional and financial support of family members (particularly his mother); (f) ambivalence toward his own family values (i.e., he identified strongly as a nobleman, but at the same time wanted to earn a living in bourgeois fashion as an artist); (g) a formal apprenticeship in the arts, starting with encouragement at the family level and culminating with study in two professional ateliers (this apprenticeship was not crowned with any recognition—his informal activity as a poster maker, illustrator, and frequenter of Montmartre bars was his true apprenticeship as this was the schooling that won him lasting fame; and (h) the luck to develop an unacademic representational style at time when the bastions of French academic art were crumbling.

Transforming Illness and Visual Art

T Zausner, Saybrook University, San Francisco, CA, USA

Glossary

Compensation Compensation is the act of substituting something to take the place of another thing that is missing. Consciously or unconsciously, many artists have created in their work what they feel is missing in their lives.

Coping mechanism A coping mechanism is a method we use to cope with stress. When faced with serious illness, artists often use creativity as a coping mechanism to distract themselves from the stress and discomfort of being sick.

Resilience Resilience is the capacity to adapt to new circumstances and bounce back from hardships even when

life has not worked out as we had hoped it would or as we had planned. It is the ability to keep going forward despite setbacks.

Self-efficacy Self-efficacy is the way that people view themselves and their actions with the conviction that the things they do make a difference. Creating works of art brings a sense of self-efficacy and accomplishment.

Transforming illness The transforming illness is a time of poor health that acts as a catalyst for transformation because it becomes a challenge to surmount. By using creativity to cope with illness, artists have changed their work and their lives.

Creativity and the Transforming Illness

Nietzsche's phrase "What does not destroy me, makes me stronger" is evident in the transformational power of major illness. Throughout the centuries, visual artists of diverse backgrounds have used creativity to turn poor physical health into a transforming illness, an experience that alters both their lives and their work. There are as many types of transforming illnesses as there are people who have them. Artists have used conditions such as cancer, AIDS, arthritis, quadriplegia, learning disorders, vision problems, deafness, and the aftermath of serious accidents as opportunities for self-evolution. A transforming illness may be an acute episode or a chronic condition, yet whenever it appears, life takes a new trajectory and things are never the same.

Transformation occurs through an interface between an illness and a person's creative response to the illness, with specific aspects of the physical condition influencing both the creative process and the art produced. Some individuals have become eminent artists after a major illness while those that were already practicing professionals have had their way of working altered and their art deepened and changed. The transforming illness can occur at any age from the beginning of life to its end, and may happen more than once. By using creativity and physical illness as a combined impetus for transformation, artists can alter their personal experience, self-expression, and ultimately cultural history.

Aspects of the Transforming Illness

There are multiple aspects to the transforming illness such as resilience, using creativity as coping mechanism, self-efficacy, mastery, compensation, and the experience of flow. Using a debilitating physical condition to improve both your life and work is an example of resilient behavior. Resilience is the capacity to bounce back from setbacks and adapt to events in life that are neither comfortable nor planned. Artists will often

use creativity as a coping mechanism during illness as a way to manage stress. Our minds can generally focus on only one thing at a time, which makes creativity an excellent coping mechanism during illness because it can distract a sick person from physical discomfort by redirecting attention toward a creative activity. The folk artist Maud Lewis (Canadian, 1903–70), who had a lifetime of pain from severe juvenile rheumatoid arthritis, spoke about this distraction saying, "As long as I've got a brush in front of me, I'm all right." Arthritis became a transforming illness in Lewis' childhood because she turned to art as a way to pass the time when poor health kept her home from school. Despite severely limited use of her hands, Lewis became a professional artist. Preferring to use her right hand to paint even though her left hand was less affected by arthritis, Lewis propped up her right hand with her left one in order to keep working.

The distraction that artists experience during creativity is explained through what the psychologist Mihaly Csikszentmihalyi described as a time of flow. In this enjoyable state where self-consciousness fades away, people can become involved in a task to the extent that they have a diminished awareness of stimuli from the outside world. The positive feeling engendered during a state of flow acts to further whatever activity is generating the experience. When creativity produces the state of flow, it becomes an impetus to continue making art.

The creative expression that takes place during illness can also be a welcome experience of self-efficacy and mastery, imparting a feeling of strength that counteracts the weakness stemming from physical problems. In addition, artists have used the subject matter in their work as compensation for activities they feel have been denied them because of illness. After a debilitating traffic accident that required a long convalescence, the painter Frida Kahlo (see [Figure 1](#)) (Mexican, 1907–54) said, "As the accident changed my path, many things prevented me from fulfilling the desires which everyone considers normal, and to me nothing seemed more normal than to paint what had not been fulfilled."

Making art during illness can become a healing experience, which like the state of flow, further encourages the activity.

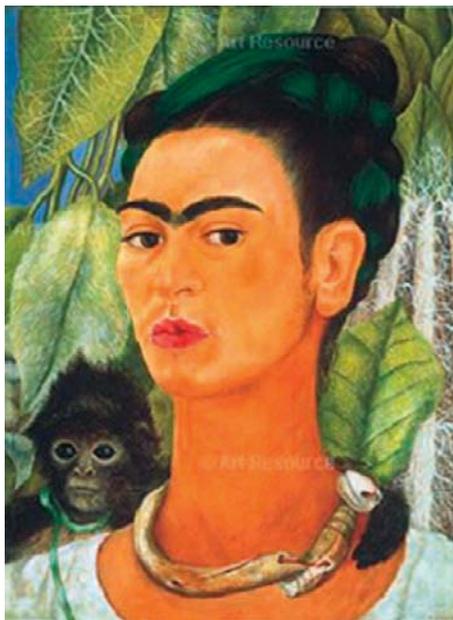

Figure 1 Frida Kahlo (1907–54) © ARS, NY *Self Portrait with Monkey*. 1938. Oil on Masonite, support: 16 x 12" (40.64 x 30.48 cm.). Bequest of A. Conger Goodyear, 1966. Location: Albright-Knox Art Gallery, Buffalo, New York, NY, USA. Photo Credit: Albright-Knox Art Gallery/Art Resource, NY Image Reference: ART389405.

The French painter Henri Matisse believed that not only was creativity healing but so were its products. He would hang his work around the beds of sick friends because he was convinced the bright colors would help them feel better as they did for him when he was sick.

The Early Transforming Illness

Many eminent artists began their careers as the result of an early illness. Some conditions were present at birth while others were contracted. Yet in all cases, the artists used creativity to pass the time when they were sick. The early transforming illness differs from its occurrence in adulthood because it is necessary for the child to have at least one attentive caregiver. In examining the lives of resilient children who came from backgrounds of hardship, the psychologists Emmy Werner and Ruth Smith found each resilient child had at least one nurturing relationship and that this supportive relationship was life changing for them. For young artists, the caregiver was not only nurturing but also encouraged the child's creativity and provided art supplies, which can be pivotal in an early transforming illness.

When Andy Warhol (American, 1928–87) became sick at age eight the art supplies his family gave him during his long months of convalescence shaped the work he would create as an adult. Warhol had rheumatic fever that progressed to chorea, an illness of the central nervous system that caused violent tremors. Although they were of very modest means, his mother believed that creativity would help him recover. She gave him coloring books, comic books, paper doll cutouts, and movie magazines while his brother Paul gave him a camera and taught him art techniques. As an adult, Warhol's paintings

had black outlines and swatches of color like coloring books; he made images of movie stars and comic book characters; the camera became central to his work, and he used paper doll cutouts in his early graphic design.

At age 18, Frida Kahlo (Mexican, 1907–54) was severely injured in a traffic accident. Incapacitated for months, her mother had a carpenter build an easel for her to use in bed and her father, a photographer and amateur artist, gave her his oil paints. Kahlo had been a premed student until she began making art during her convalescence. "Instead of studying to become a doctor," she stated "And without paying much attention, I began to paint." Kahlo had a prior transforming illness at age seven when she contracted polio and began to draw. Her father encouraged her talent and also taught her how to use a camera. Even though Kahlo sketched constantly and took art lessons, she planned on a career in medicine until the traffic accident altered her life.

Mobility problems early in life also turned Henri de Toulouse-Lautrec (French, 1864–1901) to a career in art. Research suggests he had pycnodysostosis, an inherited condition producing brittle bones that heal poorly, problems with walking, and dwarfism. Unable to be athletic like his relatives, Lautrec was instead a periodic invalid throughout his early years. Then his condition worsened as a result of two falls he sustained as a teenager that broke his leg bones. Lautrec's uncle, an amateur artist, had given him art lessons since early childhood and during his convalescence from the accidents, he focused on creativity. Acknowledging the role of illness in his life, Lautrec insisted, "One thing is certain, if my legs had been a bit longer I would never have become a painter."

Parental Pressure, Illness, and Careers in Art

For some individuals, whose families wanted them to follow more secure and established professions, it was an illness in childhood and young adulthood that halted parental pressure and allowed them to become artists. The desire to see a sick child recover was paramount to the caregivers, even if it meant that the young person would choose a less secure vocation. When Lawrence Alma-Tadema (English born in Holland, 1836–1912) developed tuberculosis as a boy, his family believed he wouldn't live much longer. In response they allowed him to stop preparing for a career in law and take art lessons. Alma-Tadema's health recovered and he became a professional painter. George Tooker (American, b. 1920), who had suffered from ulcerative colitis and a chronically inflamed appendix since childhood, acceded to family pressure to have a career in finance although he wanted to be an artist. When Tooker's intestinal problems became extremely severe in his early twenties, his parents relented and he began a career in art.

As a teenager, Henry Ossawa Tanner (American 1859–1937) knew he wanted to be an artist but his family pressured him to be a businessman. He had been a sickly child and the stress of painting at home while going to work severely compromised his health. Tanner's parents, fearing he might die, gave in and permitted him to become an artist. Tanner had a second transforming illness in his early twenties. As a young artist painting in Paris, he contracted typhoid fever and went home to Philadelphia to recuperate. It was on this trip home that Tanner reconnected with his African-American heritage and celebrated his

ethnicity in the best-known paintings of his career. Although all of these men were very sickly as children, they found art to be healing and all three of them lived long lives.

Eye Problems in Childhood and Their Influence on Art

It may appear paradoxical that an individual with poor eyesight would decide upon a career as a visual artist, yet this has happened repeatedly and with a variety of visual impairments. When the visual condition occurs in childhood, then as with other early illnesses, it is important to have an encouraging and nurturing caregiver, one who focuses on the young person's desire for creativity rather than on the presence of a visual disorder. Albert Pinkham Ryder (American, 1847–1917) had the good fortune to have such a caretaker in his father. When Ryder developed a severe inflammation of both eyes in response to a childhood vaccination, his father, knowing that his son liked to draw, gave him art supplies. The gift changed Ryder's life. He said, "When my father placed a box of colors and brushes in my hands and I stood before my easel with its square of stretched canvas, I realized that I had in my possession the wherewith to create a masterpiece that would live throughout the coming ages." Ryder's eyesight remained problematic throughout his life. Unable to see fine lines, he used broad areas of color and painted from his imagination. Ryder's poor vision created strength in his art.

When Matthew Brady (American, c. 1823–96) was a teenager, he also had a severe eye inflammation and turned to art. While making a trip to find medical care, Brady met the painter William Page, who encouraged the boy and gave him art lessons. Later, in his twenties, Brady changed from painting to photography. With diminished sight, he needed assistance to focus the camera and adjust the dials but it was he, who arranged the poses, composition, and lighting. Although Brady is well known for his portraits of Abraham Lincoln, his most famous photographs are of the Civil War. While both Ryder and Brady had lifelong vision difficulties, sometimes an eyesight correction can turn a child to art.

Nell Blaine (American 1922–96) said two things influenced her to become a painter, "One was making art when I was a sick child in bed and the other was the improvement in my eyesight from glasses and operations." When Blaine was finally able to see well, the world looked so beautiful to her that it became the subject of her art for the rest of her life. Sometimes eyeglasses can only give a partial correction as they do with Raymond Hu (American, b. 1977), who works with his eyes just inches away from the paper. Yet with parental encouragement, art lessons, and supplies, Hu started making art as a teenager and continues working today. Despite the poor fine motor control that is associated with his condition of Down syndrome, Hu perseveres and forged a new watercolor technique combining Asian and Western elements.

Learning Difficulties: Dyslexia, Attention Deficit Disorder, and Prosopagnosia

Learning disorders have also turned individuals to art. They are widespread, affecting about 10–30% of the population with

dyslexia being the most prevalent. Dyslexia, which is usually inherited, is noted by problems with reading, spelling, and writing. Now a recognized learning problem, people with dyslexia in the past were often considered to be less intelligent even though some of them like Leonardo da Vinci (Italian, 1452–1519) were geniuses. People with dyslexia often have difficulty learning a foreign language and Leonardo, who appears to have had a type of dyslexia known as surface dysgraphia, could never master Latin. As a result, he could not be a professional notary like his father nor attend university where classes were given in Latin. Instead, Leonardo decided he would become a "disciple of experience" and do his own empirical research rather than quoting the work of others. Focusing his keen mind on the natural world, he recorded notebooks filled with scientific observations. Leonardo also became an artist, a profession where education was not written in Latin but given orally in Italian.

Leonardo also appears to have a mixed form of attention deficit disorder that contains both daydreaming and restlessness as well as the ability to hyperfocus, which is the capacity to concentrate for an extended period of time. While Leonardo's restlessness often prevented him from finishing long-term projects, it helped him create short-term works such as drawings. By the end of his life, Leonardo made over four thousand drawings, a number four times greater than any other individual of his time. Leonardo employed his ability to hyperfocus during the long hours he is recorded as working on his art. He used his propensity to daydream to create inventions such as his machines. When assembled over 500 years later from Leonardo's original drawings, these machines worked perfectly.

The sculptor Auguste Rodin (French, 1840–1917) also had dyslexia. His parents wanted Rodin to have a career in the professions or civil service. Although Rodin eventually learned to read, he was unable to master Latin, spelling, or mathematics. Realizing this, his parents allowed him to study art. Both Rosa Bonheur (French, 1822–99) and Pablo Picasso (Spanish, lived in France, 1881–1973) had dyslexia. Yet Bonheur and Picasso may have become artists even without learning disorders because their fathers were professional painters who gave them art lessons from an early age.

Dyslexia has also affected the career choices of contemporary artists. Greystone Elizabeth Abbott (American, b. 1959) became a ceramic artist in response to an academic impediment in college. Yet the dyslexia that spurred her career change brought out a connection to her Native American heritage that had lain dormant until she began decorating her ceramics with tribal imagery. Chuck Close (American, b. 1940), who has attention deficit disorder and dyslexia, received art lessons in childhood and insists, "Art saved my life." In response to being considered an unintelligent, inattentive, and lazy student at school, Chuck Close worked long hours teaching himself to read. The discipline he developed as a child shapes his disciplined work habits as a professional artist. Close also has prosopagnosia, which is an inability to recognize faces. People with prosopagnosia, also called face blindness, cannot see a face in its entirety but instead comprehend the face as comprised of many separate bits of information, which when combined create their perception of a face. Close's work is completely comprised of faces created from separate small bits of information that the viewer combines into a whole image, thus seeing a face prosopagnosically, as does Chuck Close.

Adult Onset of Illness

When physical illness occurs in adulthood, either acute or chronic, it can change an established artist's way of working and may also bring benefits from what may have initially appeared to be a disaster. During the winter of 1894–95, Odilon Redon (French, 1840–1916) became ill and described his condition as “being struck by exhaustion like a thunderbolt.” Prior to that time Redon had focused on black and white work but by the middle 1890s he had begun to use color. After 1895, color work became his dominant form of expression, and Redon stated, “I am leaving black behind me.” Consuelo Gonzalez Amezcua (American born in Mexico, 1903–75) also had a transforming illness in adulthood. Amezcua was a sculptor who worked in limestone but inhaling the rock dust as she carved left her with breathing problems. Forced to change mediums, Amezcua started drawing and found she had a gift for color.

The ceramic artist David Drake (American, 1800–c.1870) was also a poet. Known as “Dave,” he had a transforming illness while a slave in South Carolina. A master potter who created large clay vessels that were used to store food before refrigeration, Dave was the first African American ceramic artist to sign his vessels and also the first to write poems on them. Sometime before 1857, Dave lost a leg, making it impossible for him to stand and kick the potter's wheel he used to shape his clay. Determined to keep working, Dave had Harry Simkins, a slave whose arms were disabled, kick the wheel for him. By 1859, Dave Drake was making the largest ceramic works of his life.

When the kimono designer Itchiku Kubota (Japanese, b. 1917) was having a second exhibition of his art at age 60, he contracted acute hepatitis. While in the hospital Kubota thought about his work and decided to develop a new style of kimono design combining ancient Japanese techniques with French Impressionism and scenes of nature. Kubota, who became very successful, spoke about the influence of having hepatitis saying, “This was the time of deepest import in my life as an artist.” Pierre-Auguste Renoir (French, 1841–1919) started to develop rheumatoid arthritis at age 56 and despite his efforts at exercise, the illness progressed. Sitting in a wheelchair with swollen immobile fingers, Renoir continued to work. With small gauze pouches to hold his brushes, the artist moved his arms rather than his wrists to make art. His son Jean Renoir admired his father's determination and said, “The more intolerable his suffering became, the more he painted.”

Creativity in Response to Cancer

One of the most prevalent illnesses in adulthood is cancer. Currently it is estimated that about one out of every three women and one out of every two men will develop this illness during their lifetime. Like the general population, artists get a variety of cancers but for the following individuals, the illness becomes a challenge that they face with creativity in a variety of ways. Some artists change their way of working or use the work specifically to address their emotional response to illness, while others like Vincent Desiderio (American, b. 1955) find that having been sick has strengthened them emotionally.

Desiderio, who had an aggressive type of nasal pharyngeal cancer, said that the ordeal of illness and treatment with chemotherapy and radiation was grueling but it changed him. He stated he now lives in the present moment and has developed greater internal strength because he no longer requires ‘validation from outside.’

Although they had different types of cancer, Darcy Lynn, Dan Savage, and Nancy Fried used art to depict their psychological response to illness and treatment as a way to manage the stress. The images they produced were often graphic depictions of medical procedures, shunts, vomiting, and breast removal that also showed their emotional anguish. After they recovered, all three individuals who remain well today used the art they created during illness as a way to give hope to others who were sick. In 1991 when Darcy Lynn (American, b. 1956) was diagnosed with Stage IV immunoblastic lymphoma, a non-Hodgkin lymphoma, she documented her entire treatment through a series of paintings and drawings. After her recovery Lynn gave lectures on the role of creativity in healing to medical personnel saying, “I fought illness with the best weapon I had – my art.”

Dan Savage (English, b. 1982), who was 20 years old when he was diagnosed with an aggressive form of testicular cancer, also depicted his treatment. Creating daily images of medical procedures and his response to them, Savage said, “I accepted it and used it for inspiration.” After his recovery, Savage became a public speaker to emphasize the necessity of early detection and treatment: “I show there is life after cancer.” Nancy Fried (American, b. 1949) had cancer four times during the years 1986–90. She had three separate types of breast cancer and also cancer of the appendix. In response, she began making sculptures of her ordeal. She showed herself with one breast after a mastectomy, having severe burns from radiation, and depicted her agony about being sick. Her sculptures became widely known. Fried, who did not have breast reconstruction and refuses to wear a breast prosthesis, openly presents herself as a one-breasted woman saying, “By making something private public, you find you aren't the only one.”

Artists with AIDS

AIDS (acquired immunodeficiency syndrome) is a pandemic but nowhere is it more prevalent than in Africa. Thirteen South African women, members of the Bambanani Women's Group, contracted AIDS and made art in response to their illness. Their names are Babalwa Cekiso, Thobani, Nomawethu, Victoria, Nloyiso, Nondumiso Hlwele, Thozama, Bongwiwe, Bulelwa Nokwe, Ntombizodwa Somlayi, Ncedeka, Maria, and Nomonde. Their creativity was part of the Memory Box Project from the University of Cape Town. It was originally intended to be expressive arts therapy for dying individuals to help alleviate stress and build a legacy to leave their children. Then with the introduction of ARVs (antiretroviral medication), the women started to recover. Despite the sometimes violent prejudice against people who are HIV positive, the women used their art as a political statement to highlight the importance of extending medical care to other low-income individuals with AIDS. They also want to encourage those living with HIV: “We want to teach people living with HIV how to live

with HIV. We want people outside to know that it is not the end of the world.” Keith Haring (American, 1958–1990) also made a political statement about having AIDS. A very successful artist with a strong interest in human rights, Haring created posters about AIDS awareness and established a foundation to continue his work. It is the Keith Haring Foundation that carries on his commitment to assist both AIDS organizations and children. John Dugdale (American, b. 1960) was a commercial photographer who used AIDS to change careers and do the fine art photography he always wanted to do. Despite the multiple opportunistic infections associated with AIDS that caused him to lose half of his hearing and most of his eyesight, Dugdale, who says he views the world as if peering through six Baggies, has achieved success as a fine art photographer and insists that, “In illness there is an unbelievable opportunity for freedom and change.”

Color Vision Deficiency and Its Influence on Art

One of the most common visual impairments is color vision deficiency, also known as color blindness. Usually an inherited condition, it affects one in ten men and one in two hundred women. The degree of impairment can range from a slight inability to see colors to a profound lack of color discrimination. Although people with color vision deficiency have problems perceiving color, they have an enhanced ability to distinguish gradations of light and dark along with an acute perception of textures and patterns. Color vision deficient artists use this acuity in the gradations of light and dark that empower their work.

One of the most famous artists in Western culture, Rembrandt Harmenszoon van Rijn (Dutch, 1603–69), is believed to be color vision deficient. A. Hyatt Mayor, a curator at the Metropolitan Museum of Art, who was the first to recognize this in Rembrandt’s work, also noted that Rembrandt’s difficulty in perceiving colors gave him an increased sensitivity to tones of light and dark (see Figure 2). He said of Rembrandt that “seeing the world more or less in browns freed him to calibrate luminosity with a delicacy as expressive as any palette of colors.” Color vision deficiency also helped Rembrandt with his etchings, which was a black and white medium in the seventeenth century.

Although it is unusual to find a female artist with color vision deficiency, Kaethe Kollwitz (German, 1867–1945) appeared to have this condition. Kollwitz, who showed talent at an early age and wanted to be a painter, realized in art school that her color perception was flawed. She said, “In the painting class I made no progress. Color was my stumbling block.” In response, Kollwitz stopped making oil paintings and focused on black and white or brown and white imagery in etchings, drawings, and lithographs. She also turned to sculpture, another medium without color in which she could excel. Paul Manship (American, 1885–1966) also had color vision deficiency and changed to sculpture after difficulties with color in his paintings. Charles Meryon (French, 1821–68) was another artist with color vision deficiency who stopped painting and achieved success with his black and white etchings.

Lack of color in an artist’s work cannot be used as the sole criteria to assess a person’s level of color vision. Odilon Redon and Chuck Close worked almost exclusively in black

Figure 2 Rembrandt Harmensz van Rijn (1606–69) *Belshazzar's Feast*, about 1636–8. Oil on canvas, 167.6 x 209.2 cm. Bought with a contribution from The Art Fund, 1964. (NG6350). and white for the first half of their careers before going on to become major colorists. Caravaggio (Italian, 1573–1610), born Michelangelo Merisi, showed an excellent sense of color in his early work but preferred a reduced palette emphasizing light and dark in his later paintings.

Artists with Macular Degeneration

Macular degeneration, which is a disease of the retina, is one of the most common causes of vision loss in older adults. In this illness, the macula, which is the central part of the retina, becomes damaged leaving the affected individual with only peripheral vision. Although this illness usually found in individuals aged over 55, Edgar Degas (French 1834–1917) had his first symptom at age 36. The condition, which began in his right eye, eventually affected his left eye as well. Even without central vision, Degas was determined to work. Unable to stand the glare of the sun, Degas painted indoors, creating interior scenes, portraits, and images of ballet dancers. When his eyesight deteriorated so that he could no longer see the fine lines his brush made with oil paint, Degas changed to pastels where the thick chalk lines were easier to see. These pastels are his most popular works. As his vision worsened and Degas could no longer see the chalk lines, he turned to sculpture, using his hands to help in his determination to remain creative.

For most of her life, Georgia O’Keeffe (American, 1887–1986) had excellent vision but in her later years, she developed wet macular degeneration in both eyes along with a rupture of capillaries in the retina of her left eye. Faced with diminishing vision, O’Keeffe started to simplify her forms. She also worked from photographs and from her memory saying, “You paint from your subject, not what you see.” For a while, O’Keeffe, like Degas, turned to sculpture, but she returned to painting, stating that it was central to her life.

Deafness and Art

Deafness, which is a widespread condition, can be an early influence toward a career in art. It may happen when deaf children use art as a means of communication with their hearing parents as it did with John Lewis Clarke, Ann Silver, and Harry R. Williams. When John Lewis Clarke (American, 1881–1970) was three, he became deaf from scarlet fever. As a boy who was unable to speak, he used clay from the Montana riverbanks near his home to sculpt animals as a way of telling his parents what he had seen that day. Clarke, who became a sculptor specializing in animals, eventually learned to sign in two languages, his Native American Blackfoot sign language and the ASL (American Sign Language) that he learned in schools for the deaf. Ann Silver (American, b. 1949), who was born deaf, also used art in childhood as a way of communicating with her hearing family. A professional artist, Silver still uses art as communication but now it is to promote deaf culture. Harry R. Williams (American, 1948–91) was eighteen months old when he lost his hearing after a reaction to the antibiotic streptomycin. At age four Williams started to draw in an effort to communicate with his hearing parents and as an adult, he became famous in the deaf community for his exquisitely drawn symbolist paintings.

Perhaps the best-known artist with a hearing problem is Francisco Goya (Spanish, 1746–1828, also known as Francisco de Goya y Lucientes). In 1792, Goya lost his hearing after a severe illness that kept him incapacitated for months. Goya's precise diagnosis is unknown but after becoming deaf his art transformed and his production increased. Goya began his career as a painter of colorful canvases with scenes of pleasant pastimes but after losing his hearing his work became darker, more structured, and filled with political and psychological content. After his illness, Goya turned into a romantic painter and is considered a precursor of modern art.

Accidents and Their Legacy in Art

Creativity that starts during convalescence from serious accidents may begin a career in art as it did for David Cox and Frank Day. David Cox (English, 1783–1859) was a blacksmith who broke a leg and started drawing during his recovery. Unable to return to the forge Cox studied painting. He became very successful, exhibiting at the Royal Academy and writing books on art. Frank Leverall Day (American, 1902–76) was a migrant agricultural worker when a farm accident in 1959 broke both of his knees. Day, who began to make art in the hospital rehabilitation program, continued for the next sixteen years until his death. As a Konkow Maidu from California, Day created over two hundred paintings of Native American customs, ceremonies, and legends. Art became a way of preserving his culture for Day, who said, "If I do not do this, all things will be forgotten."

Traffic accidents, a leading cause of disability and death, can inflict severe injury whether people are drivers of cars like Ginny Ruffner or passengers like Howardena Pindell. In 1979 Pindell, an art professor, was riding to work at her university with two colleagues when a woman, who had been given pain medication, swerved across the meridian and hit their car.

Pindell was trapped in the back seat, her hips misaligned and unconscious from a concussion. In response to the trauma, Pindell said, "My work changed drastically." She went from abstract painting to autobiographical imagery featuring a slave ship to acknowledge her African-American heritage. While the hip injury healed, Pindell still has neurological problems. Although she cannot see all the objects in her visual field, Pindell says she now has the ability to focus intensely on repetitive tasks and uses this ability to create intricate patterns in her paintings.

Ginny Ruffner (American, b. 1952) described her near fatal auto accident in 1991 as "five weeks in a coma, five months in the hospital, and five years in a wheelchair." Trying to avoid another car that had cut across both lanes Ruffner lost control of her vehicle, crossed the median, and spun into ongoing traffic where she had a head-on collision with a first car and then was hit by a second one. In addition to great physical damage, Ruffner suffered a shearing brain injury; her doctors did not think she would live. Yet despite paralysis of her left side that included her drawing hand, double vision, spasms, and a seeming total loss of memory, Ruffner survived. When friends and family brought images of her work, Ruffner began to retrieve memories of her art and started to draw with her right hand. She said, "I knew I would make art again" that making art "was what brought me back." Ruffner now creates by making drawings and supervising assistants who build the finished sculpture. In addition to her previous medium of glass, Ruffner has expanded her work to include metal and book design.

Working with Quadriplegia

Auto accidents can also result in quadriplegia as they did for Ernie Pepion and John Callahan. Yet after being injured both men changed their lifestyles, went to college, and became artists. Ernie Pepion (Eewokso, American, 1943–2005), who worked from a motorized wheelchair with a hand and forearm brace to support his right hand, said, "I am an artist, Blackfeet Indian, and am physically disabled." Pepion used his paintings as political/psychological statements to counteract prejudice against quadriplegia and people of color. John Callahan (American, b. 1951), now one of America's leading cartoonists, is also an author, filmmaker, and a role model for other disabled people. Callahan draws by sitting in a motorized wheelchair with a tablet on his lap using his left hand to brace his right.

Sports accidents are another cause of quadriplegia. Cindy Bernhardt (American, b. 1963) was a freshman in college when she was injured in a gymnastics accident and Trevor Wells (English, b. 1956) was an apprentice carpenter age 21 when he was injured playing rugby. Completely unable to use their hands, both of them started making art in hospital rehabilitation programs and went on to have success as painters by holding brushes in their mouths.

When a blood clot lodged in his spine at age 47, Chuck Close (American, b. 1940) became quadriplegic. With very limited movement in his arms and legs, Close paints while sitting in a wheelchair with braces on his legs and a Velcro brush holder attached to his wrist. Two years before the illness Close, who had painted in black and white, began

experimenting with color. After the incident, his palette expanded and he has become a colorist. A disciplined worker who paints steadily, Close stated that "Every day when I roll out of my studio and look over my shoulder, I say 'That's what I did today.'"

Multiple Transforming Illnesses

While Frida Kahlo, Henry Ossawa Tanner, Nell Blaine, Itchiku Kubota, Chuck Close, Lawrence Alma-Tadema, and Odilon Redon all had more than transforming illness, few individuals have had their lives and art as affected by incidents of poor health as Henri Matisse (French, 1869–1954). He had five transforming illnesses. Matisse's first transforming illness came at age 20 when intestinal problems he had since childhood flared into an acute attack. Forced to recuperate for months, and hoping that creativity might help his boredom, Matisse asked for art supplies. Upon receiving them from his mother he said, "The moment I had this box of colors in my hands, I had the feeling that my life was there." When Matisse was in his late forties, bronchitis, his second transforming illness, forced him to move to the south of France. The beautiful colors of the Mediterranean brightened his palette and he became a great colorist (see Figure 3).

Intestinal cancer at age 70 was Matisse's third transforming illness. After an operation that went poorly, Matisse became an invalid for the rest of his life. Unwilling to stop working, he started drawing from his bed and then cut out pieces of colored paper while working in a wheelchair. Compositions made of colorful cut paper became a main form of expression for Matisse and include some of his best work. His fourth

Figure 3 Henri Matisse (1869–1954) *The King's Sadness* (La Tristesse du roi). 1952. Cutout. Inv. AM 3279 P. Photo: Philippe Migeat. © Succession H. Matisse, Paris/ARS, NY. transforming illness was a gallbladder condition that came soon after the intestinal surgery. Refusing another operation, Matisse sublimated his pain by making book illustrations. The fifth transforming illness came in 1942 when Matisse's poor health required a nurse. The young woman who was his nurse later became a nun and in 1947 she asked him to design a church. Matisse was 84 when he finished the *Chapel of the Rosary* and said, "I consider it to be my masterpiece."

The courage and determination of Matisse and other artists to face hardship with creativity indicates the transforming illness is a widespread phenomenon and fundamental to the human condition. Yet the transformation of trauma into creativity is not limited to the visual arts but is found throughout the life histories of accomplished people in all domains (Goertzel and Goertzel, 1962; Sandblom, 1996). Like the steel in the blade of a samurai's sword that repeatedly meets the flames and the hammer, these individuals who endure adversities emerge stronger and more resilient – and they continue to be creative.

Glossary

Cortical arousal Level of brain activation, measured physiological through brain waves, ranging from quiet and unfocused dreaminess to intense and sharp concentration.

Incubation A stage in the creative thinking process in which preliminary problems gestate for an unspecified period of time without conscious attention to their resolution.

Insight Often referred to as illumination or the ‘aha’ experience, a stage in the creative thinking process, following incubation, in which previously unconscious connections become revealed to the conscious mind.

Intuition A vague and anticipatory feeling of an implicit solution to a creative problem that is based on a hunch supported by extensive knowledge and experience in a given domain.

Preconscious A level of arousal that lies between the conscious and the unconscious in which playful, analogical,

and combinatory mechanisms function to aid creative thinking.

Primary process A tendency, according to psychoanalytic theory, to satisfy sexual and aggressive tensions indirectly through imaginative, emotional, and irrational means.

Progression in the service of the ego A cognitive style process employed by creative thinkers to facilitate the conscious organization and communication of valued ideas.

Regression in the service of the ego A cognitive style process employed by creative thinkers to delve into the unconscious and interrupt rational constraints on new ideas.

Secondary process A tendency, according to psychoanalytic theory, to resolve instinctual tensions through the use of logical, realistic, and conscious mechanisms.

Sublimation In psychoanalytic theory, the unconscious displacement or redirection of sexual and aggressive drives into socially acceptable and creative activities.

Anecdotal Background

At least as far back as Archimedes in the bathtub, the emergence of a creative solution to a problem, with less than fully conscious attention, has been the subject of both conjecture and awe. How was the ancient Greek scientist, by engaging in a very ordinary activity, able to determine the method for measuring the amount of gold in the king’s crown through the displacement of water? Inspiration deriving from unconscious sources is presumed to be a primary factor in achieving poetic success, creating an artistic legacy, producing musical compositions, and other inventive or creative accomplishments, as well as in resolving scientific conundrums. The unconscious well-springs of creative activity are imbued with mystery, reverence, and even fear for their potential disappearance. Creators whose work may depend upon a fragile coalition of characteristics and circumstances are wary that the muse may depart, that the guiding spirit or the divine inspiration will leave them barren. There is concern that what may not be readily grasped – the essence of their creative powers – which may not be obvious to conscious exploration, could be easily and inexplicably lost. Perhaps, the creative unconscious represents to both creators,

and to those who study them, simply a summary of what is still beyond our grasp: a more complete analysis of what it means to be creative and how to best actualize the potential for producing creative work.

Accounting for how the unconscious contributes to creative achievements in various fields does not depend exclusively upon stories dating back several millennia. Many examples range from the mathematician Poincaré’s demonstration of Fuchsian functions, to the chemist Kekulé’s discovery of the benzene ring, to Coleridge’s poem about Kubla Khan, to Darwin’s theory of evolution, to Mozart’s musical melodies, and to Gutenberg’s invention of the printing press. In fact, the classic collection of first-hand reports published by Brewster Ghiselin in 1952 has been one of the most widely cited publications in the creativity literature. These and other descriptions often reveal a strong belief on the part of the creator that subconscious processes are quite involved in the path from dimly perceived to fully thought out creative ideas.

The apparent automaticity in creative activity noted by Ghiselin, however, is not to be interpreted as antithetical to conscious processes, but instead as a balancing factor that aids in loosening the normal constraints of reality:

(A)utomatic invention, far from being a sign of diminished, imperfectly functioning consciousness, is a healthy activity supplementary to conscious invention and in no way inconsistent with it. The automatic functioning in invention is, rather than an inferior or suspect substitute (or an exalted one), an extension of activity beyond the limited scope of that which is shaped by insight, the conscious activity, which is an observant adjustment of exactly appreciated means to known ends. Something beyond that fully observable conscious construction takes place, to the advantage of consciousness, or of the consciousness able to make use of it. (p. 17)

Examples of the interplay between conscious and unconscious factors from the reports of the creators in Ghiselin's volume include the musician Roger Sessions who claimed that the composer "is not so much conscious of his ideas as possessed by them (and) often is unaware of his exact processes of thought till he is through with them" (p. 49), the sculptor Henri Moore who stated that for the artist "the nonlogical, instinctive, subconscious part of the mind must play its part in his work, (but) he also has a conscious mind which is not inactive" (p. 73), and the poet Amy Lowell who defined the need for "an extraordinarily sensitive and active subconscious personality, fed by, and feeding, a nonresistant consciousness" (p. 110).

The challenge for researchers in the realm of creativity in the twenty-first century is to effectively demonstrate how processes of thinking that a person is not aware of can lead to significant creative achievements. Beliefs from ancient times have carried over into the social and biological sciences of the past century. It is difficult to ignore the persistence of creators from a variety of domains that unconscious influences are critical components in the development of their work. While the lack of concrete evidence to support claims about unconscious processing may not be sufficient to give up this notion, building a case that fully explains how this is accomplished is likely to be several decades away. However, understanding the potential foundations for interweaving the conscious and the unconscious aspects of creative thinking is a worthy beginning.

Freudian Roots

Comprehensive psychological elaboration of the relationship of creative thinking to unconscious processing was first explored in the work of Sigmund Freud. Based on his few retrospective studies of the lives of creators such as Leonardo da Vinci and Dostoevski, Freud attempted to explain creativity as motivated by the desire to maximize personal gratification. The essential concept that pertains to creativity from a psychoanalytic perspective suggests that the sublimation of tensions resulting from unconscious instinctual drives is responsible for all human progress. Furthermore, sexual and aggressive needs are expressed indirectly through a mechanism which Freud labeled as primary process thinking. In contrast to the more rational, logical, realistic, mature, and clearly conscious secondary process thinking, the primary process is imaginative, irrational, emotional, childlike, and uncontrolled. It is presumed that the creative individual is somehow able to employ primary process thinking to effectively thwart anxieties while engaging in culturally sanctioned behaviors (e.g., writing a song, producing a play, constructing a theory, or inventing a new machine).

Psychoanalytic theory cast a long and dominating shadow over twentieth-century efforts to explain the nature of creative thought, particularly in the artistic and literary milieu where the residue of emotional conflict seems to be played out more directly in the works of fiction, composition, and painting. Personality qualities associated with the development of parent-child relationships, disguised by the defensive alterations of the unconscious or in the context of regressive and spontaneous activity, possibly interwoven with elements of neurotic or even psychotic behavior, served as a rich mine to be explored for creative ores. Freud was surely not alone in his approach to untangling the threads of creative motivation; however, his views had serious limitations which led Albert Rothenberg to conclude, in his 1990 treatise entitled 'Creativity and Madness,' that Freud merely replaced "the Platonic idea of possession by an external factor . . . to a factor that is external to awareness" [the unconscious] p. 50.

Although Rothenberg does not dismiss the value of unconscious influences on creative activity, he and others have pointed out that Freud's definition of the unconscious as a kind of repository for creative ideas contradicts the *sine qua non* of creativity – originality. Is it really possible to create something truly unique if the elements of the achievement already reside in the past, locked away in the unconscious until stimulated by anxiety or insanity? In addition, Rothenberg also questioned how the motivational power of the unconscious to direct creative behavior is commensurate with its distorting functions to alter thought so that it cannot be easily recognized by the conscious. Whatever benefits might be obtained by immersion into the emotional themes and flexible play with material in the unconscious, creative accomplishments ultimately require the unity, organization, and control that must be accessible to awareness.

The key legacy of psychoanalysis is that the distinguishing feature of all creative individuals is their mastery of the ability to utilize the primary process to the degree that ideas can be transformed into meaningful and communicable symbols. Freud himself acknowledged that he did not understand how this actually worked. Standard criticisms of psychoanalytic theory may illuminate why Freud was never able to complete his explication of the creative process. For example, retrospective accounts of creativity do not permit the researcher to actively examine the thoughts or behaviors of the creator. Second, the limited sampling and lack of empirical methodology makes generalization extremely difficult. Finally, the heavy emphasis on sexual and aggressive instincts appears to reduce the scope of application from creativity in diverse realms of human achievement. One of Freud's most important colleagues, Carl Jung, provided another variation on early psychoanalytic theories of the role of the unconscious in creativity.

Neoanalytic Concepts

Movement away from the orthodox psychoanalytic view, emphasizing creative acts as a result of instinctual drives and the sublimation of anxieties, was fostered by the neoanalytic theorists who stressed the control of primary process thought and its adaptive connections with the secondary processes of

the ego. In contrast to describing creativity as a defense mechanism or in terms of coping with frustration, the modifications of Freud's doctrine were to effectively reverse the transcendence of the id over the ego and to allow creative activity to attain a higher priority than sexual or aggressive instincts. The most significant conception forwarded by the neoanalytic tradition was regression in the service of the ego, detailed in 1952 by Ernst Kris. This process consisted of an oscillation between two phases, usually over a lengthy period of time. An inspiration phase involved the breakdown of rational barriers to allow the influence of external, varied ideas and images within the mind. Counterbalancing this process, Kris also postulated an elaboration phase in which the constraints of reality are meaningfully imposed to select and synthesize the critical themes of a problem.

In the introduction to his 1973 volume on theories of creativity, Morton Bloomberg further outlined the process:

During controlled regression, the ego, or rational element, maintains the power to regain command over any large-scale invasion by unconscious material which threatens with selfish and forbidden pleasures. Hence the id, or instinctual impulses, neither overthrows the ego nor is it sealed off from consciousness. The ego uses chaotic, irrational, bizarre thinking to play a constructive role in problem solving and directs the individual away from self-destructive action. (p. 3)

Therefore, the neoanalytic position engendered a shift from an essentially irrational, unconscious eruption of material controlling the creative process to a somewhat more cognitive approach in which creativity is shaped by reason and critical evaluation.

Lawrence Kubie, another psychoanalyst, suggested in his 1958 book that preconscious processes must mediate between the primary or unconscious level and the secondary or conscious level of thought. He stressed the adaptive and healthy aspect of creative thinking and believed that the playful, analogical, and combinatory mechanisms of the preconscious should not be "anchored either to the pedestrian realities of our conscious symbolic processes or to the rigid symbolic relations of the unconscious" (p. 141). Both Kubie and Kris share with Freud a basic tenet of the psychoanalytic perspective; that is, the source of creative inspiration is not readily accessible to awareness. Whether the emphasis is on the preconscious, a regression to the unconscious, or to the unconscious itself, neoanalytic theorists relegate creative drive to the nonconscious or subconscious realm. The question remains whether this psychoanalytic structural division of consciousness, including the conflict between primary and secondary processes, adequately accounts for the nature of creativity activity.

One example of the type of early neoanalytic research that promoted the value of unconscious mechanisms as a healthy approach to creative accomplishment was to employ projective techniques, such as the Rorschach inkblot or Thematic Apperception Tests (ambiguous drawings), in order to assess the process of adaptive regression. Robert Holt's method for scoring the Rorschach has the advantage of allowing researchers to measure both the use of primary processes as well as the extent that they are adaptively controlled by secondary processes. While the validity of projective techniques has been a controversial topic, particularly with respect

to clinical diagnosis, their contribution to understanding the notion of adaptive regression has potential pending further investigation. In his extensive 1980 review of primary process thinking and creativity, John Suler concluded that the majority of "projective test studies provide evidence that the *integrative control* of primary process is an important aspect of creative thinking" (p. 153).

In his 1993 analysis of the myths associated with creative thinking, Robert Weisberg has suggested that there is little evidence to support any version of psychoanalytic theory. He discounts both primary process thinking and the role of the unconscious as at all significant to creativity. Instead, he argued that creative production is the result of ordinary thought processes, augmented by particular abilities, specific areas of training, and high levels of motivation. Weisberg acknowledged that the neoanalytic approach involves a blend of primary and secondary process thought, but that the "emotionally laden, unconscious associations based on unsatisfied childhood needs are still assumed to be limited to primary process thinking" (p. 31). Thus, the legacy of Freud and his neoanalytic followers was an unfinished portrait of the relationship between affective and cognitive processes in creativity.

Incubation, Insight, and Intuition

The history of the unconscious in creative thinking is apparently linked to a variety of similar terms that all imply the lack of conscious attention as part of the process in which the creator is able to follow through a sequence from the germ of an idea to its more complete resolution. Three examples of this type of concept include incubation, insight, and intuition, all of which have been discussed widely as representative of the nonconscious components of creativity. Complicating the analysis of such terminology are related words – for instance, insight may often be referred to as illumination. While Weisberg and other researchers continue to insist that all creative thinking is based on logical, ordinary, problem-solving processes, and that incubation, insight, and intuition are old myths, many contemporary theorists maintain support for these nonconscious contributions. In her 1996 chapter on affect and cognition, Sandra Russ presented a model that incorporates several elements of primary process thinking, such as adaptive regression and insight abilities, as facilitating factors in creative thought.

Perhaps the earliest well-developed conception of the notion of incubation in the understanding of creative thinking was postulated in 1926 by Graham Wallas. He articulated four stages – preparation, incubation, illumination, and verification – in what was described as a linear process of thought. During the incubation stage, the preliminary ideas of the preparation stage are allowed to gestate for an unspecified period of time while the problem is not pursued consciously. The culmination of the incubation process is the explosive stage of illumination, which is to be followed by the final, and more prosaic, verification stage. Although Wallas did not really discuss how the process of incubation worked, nor did he recognize the nonlinear possibilities of these stages, later metacognitive theorists, Bonnie Armbruster for example,

in reviewing the self-analysis of several creative thinkers, concluded in 1989 that “during the incubation stage the interconnected network of flexibly organized knowledge . . . is being restructured into new schemata” and, that unconsciously, “(c)reative individuals may have a superior metacognitive ability to separate the wheat from the chaff” (p. 179).

Illumination, or insight (the ‘Aha!’ experience), is the moment when the previously unconscious connections become revealed to the conscious mind. Armbruster again stated that illumination is the “recognition of a mental representation that fulfills, or has the potential of fulfilling, the goal of the creative enterprise” (p. 180). The presumed spontaneity of insightful experiences in creative thinking is undoubtedly exaggerated, embellished by selective memory, frequently divorced from the context of the lengthy preparation leading up to it, and probably far rarer than popular reports would suggest. Nevertheless, the transitions from preparation to incubation to illumination in the creative process do reflect the notion of unconscious, and as of yet not fully identified factors, in the accomplishment of many extraordinary human creations. The concept of insight in problem-solving dates back very clearly to the 1930s work of the Gestalt psychologists on resolving mental blocks and avoiding the pitfalls of repetitive and routine mental pathways. Yet Robert Sternberg and Janet Davidson have edited in 1995 a large volume entitled *The Nature of Insight* which suggests that interest in this area has resurfaced.

Caught between the subconscious wanderings of the incubation stage, and the momentary flash of insight or illumination, is the sense of creative intuition. In her 1995 review of the intuition concept, Emma Policastro defined it as an implicit form of information processing in which vague and anticipatory perceptions orient and constrain the direction of a creative search. Intuition can be viewed as the unconscious bridge from incubation to insight. The research team of neurobiologist Antonio Damasio provided evidence in 1997 that the intuitive hunches of people are nonconscious signals that “act as covert biases on the circuits that support processes of cognitive evaluation and reasoning” (p. 1294). Similarly, in his 1988 chance-configuration theory of creative thinking, Dean Simonton suggested that the intuitive genius is characterized by “numerous infraconscious but behaviorally and emotionally active associations” (p. 46) that provides the opportunity for combining appropriate elements in new ways. It is evident that intuition is based on extensive experience and knowledge within a particular domain, somehow connected at a nonconscious level, and yet the explanation of this phenomenon still leaves many unanswered questions.

Brain Physiology

Creative thinking is, of course, ultimately dependent on the functioning of the human brain, conscious or otherwise. Damasio was not the only neurobiologist to speculate about the unconscious as a legitimate realm for conducting scientific research, but he has very clearly postulated a brain mechanism that assists in the solving of problems through a covert examination and preselection of options of which only a few are presented for conscious evaluation. In his 1994 analysis of

the fallacy of Cartesian dualism, Damasio cited the views of creative scientists who support the interconnection of reason and emotion. Although the goal of his work is not to discuss creativity per se, the reality of the unconscious is stressed: “It is as if we are possessed by a passion for reason, a drive that originates in the brain core, permeates other levels of the nervous system, and emerges as either feelings or nonconscious biases to guide decision making” (p. 245). It is important to recognize that Damasio is not maintaining that the unconscious is the source of problem solutions, merely that those decisions are facilitated by the activation of multiple regions of the brain.

One of the more persistent beliefs in recent decades has been that creative thinking is predominantly a function of the right hemisphere of the brain. In contrast to the logical and conscious processing of the left hemisphere, the right brain is purported to specialize in the emotional and symbolic processing necessary for creativity. However, a number of empirical investigators, such as Ingegerd Carlsson in 1992 and Klaus Hoppe and Neville Kyle in 1990, have concluded that cooperation between both right and left hemispheres is characteristic of the brains of creative thinkers. There is little evidence to conclude that either the unconscious or the primary process would be attributed to right hemisphere functioning while conscious and secondary process thinking would be relegated to the left hemisphere. As R. E. Ochse pointed out in 1990, there is a common tendency to misconstrue levels of consciousness as particular regions of the brain rather than as a continuum of arousal. Referring to the unconscious as a particular brain structure reflects the nineteenth-century biology that served as the basis for psychoanalytic theory.

Reformulation of the role of the primary process in creative thought was summarized by Colin Martindale in 1989 as a state of defocused attention occurring during a period of relatively low cortical arousal. He believed that connections among different ideas, represented by interneuronal associations, are at the heart of creativity. In states of low cortical arousal, the creator is able to shift easily his or her focus from one node (cluster of neurons) to another. The simultaneous activation of many nodes increases the probability that relationships among them will emerge. In higher states of cortical arousal, more intense focus is placed on a fairly limited number of nodes, decreasing the likelihood that connections will be achieved. Several studies by Martindale and his colleagues have provided support for these differences in levels of arousal, particularly during the inspiration stage of the creative process. In addition, he suggested that creative individuals are “more variable in their level of arousal than are uncreative people; that is, they may show more extreme fluctuations” (p. 219), perhaps a physiological rewording of the concept of regression in the service of the ego.

While Ochse also recognized the merit of low levels of arousal in dissipating attention so that new combinations of elements might form, she further suggested that creators will use these ordinary mechanisms more effectively because they “engage persistently and independently in activities relating to their field of work, and thereby acquire a potentially valuable store of automatic routines” (p. 247). Low levels of arousal, whether in dreams, drug-induced states, or everyday reveries,

do not necessarily lead to creative achievements with any greater certainty than do the primary process or regression mechanisms forwarded within the psychoanalytic perspective. Therefore, it is neither the amount nor the process of unconscious thought that distinguishes the creative person, but the depth of content related to their field that may better permit 'automatic' integration of different ideas. Unconscious automaticity is apt to occur in any individual with respect to relatively trivial insights, whereas the most creative breakthroughs depend upon a large repertoire of experience and knowledge that have been established through an extensive network of neuronal interconnections.

Cognitive Models

Parallel to the developments in understanding brain physiology in recent decades has been the explosion of knowledge from cognitive and information processing researchers. It is no surprise that contemporary theorists have attempted to integrate the introspective reports and psychoanalytic processes presumed to be operable in the creative unconscious with the cognitive models that have typically addressed more logical and conscious elements of thought. Probably the earliest effort in this direction was the 'blind-variation and selective-retention' model advocated by Donald Campbell in 1960. He drew an analogy between the evolutionary process of genetic mutation and the almost random combination of ideas that might fuse in the mind of the creative thinker. Dean Simonton elaborated extensively on this approach in 1988 when he proposed his 'chance-configuration' theory in which original work is dependent upon a rich but flexible set of associative connections that provide the context for chance variations. He stated that:

In chance permutations, mental elements evoke other elements by such rare routes that any configuration so generated must be considered an essentially random confluence of psychological events. The appearance of unpredictability is reinforced by the fact that so many of the associative linkages operate at the infraconscious level, making it difficult to reconstruct cognitively the origin of chance configurations. (p. 48)

Previous dismissal of Freudian theory, including references to unobservable phenomena such as the unconscious, has led to isolation and rejection of neoanalytic theorists, resulting in the lack of cooperation in exploring complex notions like creativity. The resurgence of interest in revised perspectives on the unconscious is exemplified by a collection of eight articles on the topic in a 1992 issue of the *American Psychologist*. In the lead article, Elizabeth Loftus and Mark Klinger concluded that there is no longer any question about the existence of unconscious processes in human thought, but consensus about how such mechanisms operate has yet to be achieved. Although the current literature on unconscious cognition is much too voluminous to be reviewed here, much of the empirical support for this concept has been produced by Anthony Greenwald and his associates. One conclusion that he reported in 1995 was that his evidence is consistent with a view of the unconscious that can be supported by the newer parallel distributed network interpretation of the traditional serial information

processing approach. In sum, there appears to be no inherent contradiction between contemporary cognitive research and a significant role for the unconscious in creative thinking.

Excellent illustrations of the renewal of interest by cognitive theorists in the unconscious are the books and edited works of Steven Smith, Thomas Ward, Ronald Finke, and colleagues. In their 1997 collection, entitled 'Creative Thought,' they defined the field of creative cognition as a "relatively new area of investigation that attempts to characterize creativity in terms of fundamental cognitive processes acting on previously stored knowledge" (p. 4). Chapters in their 1995 book, *The Creative Cognition Approach*, included George Mandler's discussion of the unconscious influences on creativity (particularly the 'mind popping' that follows an incubation period), Kenneth Bowers and associates' analysis of the interplay of conscious and unconscious processes in the conceptualization of intuition, and Jonathan Schooler and Joseph Melcher's research which indicates how the conscious verbalization of thoughts may inhibit the achievement of creative insights. In their other 1995 book, *Creativity and the Mind*, Ward, Finke, and Smith described incubation, intuition, and insight all in terms of the unconscious activation of a network of associations.

A somewhat different angle was suggested by Lloyd Noppe in 1996, drawing on the psychological differentiation theories of Heinz Werner and Herman Witkin, as well as the neo-Piagetian constructive-operators model of Juan Pascual-Leone. This model incorporates the cognitive styles of fixity-mobility and field-dependence-independence in an affective-cognitive blending of the primary and secondary processes of regression and 'progression' in the service of the ego. The strategies of creative thinkers are flexible enough to adapt to the demands of complex problems because they effectively balance the combination of executive processing skills with a rich collection of relevant experiences. Creators are systematic and analytic thinkers, but they are also amenable to a relaxed formation of impressions based, at first, on varied elements that may be disconnected and not fully formulated. Regression to unconscious levels of awareness, including sensitivity to the knowledge and issues of one's specific field of creativity, must be coupled with a corresponding progression through a rational and organized set of strategies for communicating the breakthrough.

Mihaly Csikszentmihalyi's 1996 analysis of his interviews with 91 creative individuals provided fresh documentation of the value of the unconscious. While again the methodological ambiguities of introspective self-reports of the creative process still apply, he found frequent reference by these creators to the notions of insight, intuition, and incubation. Csikszentmihalyi distinguished between the psychoanalytic concept of the unconscious, driven by the motivation to achieve resolution of hidden tensions, from cognitive accounts, which posit no predetermined direction, only the potential for attaining useful connections. He further points out that irrelevant connections would eventually dissipate whereas the useful ones would emerge into consciousness. In focusing on the relationship between the conscious and the unconscious, Csikszentmihalyi describes a difficult contradiction: "not to miss the message whispered by the unconscious and at the same time force it into a suitable form. The first requires openness, the second critical judgement" (pp. 263-264).

Contemporary Controversy

At the present time, Weisberg continues to maintain that experimental evidence for the existence of unconscious processes in creativity is required, but not yet demonstrated. He dismisses anecdotal reports as unscientific and minimizes the contributions of previous laboratory studies as inconclusive. Weisberg, however, does acknowledge the necessity of explaining apparently unconscious mechanisms such as incubation, illumination, and primary process thought, given the frequency and certainty with which so many creative persons report such phenomena. The ordinary thought processes he purports to be responsible for creative thinking do not yet account for the unconscious inspiration that appears to motivate many creators.

In his impassioned analysis of the conscious and unconscious aspects of the mind, Guy Claxton has reviewed historical and cultural traditions of trust in thought that is not largely logical and rational. He describes the Western ideal of scientific thinking as limited and exclusive of alternative ways of knowing and understanding the world. It is important to recognize that he does not reject conscious processing as valuable to the creative process, but he does call for the rediscovery of how the unconscious equally contributes to creativity. Citing such diverse sources as Shakespeare's plays, Einstein's theories, and Buddhist philosophy, Claxton maintains that our society needs to balance our obsession with analytical science by greater acceptance of ambiguous, paradoxical, and patient reflection about creative issues. He believes that the "voices of philosophy, poetry and imagery are relatively weak in a world that largely assumes that only science and reason speak with authority. Thus, paradoxically, it is only science itself that can bring credible tidings of unscientific ways of knowing" (p. 226).

During the last decade, experimental research has, in fact, been conducted that is highly suggestive of the value and the veracity of unconscious elements in creative thinking. Sophie Ellwood, Gerry Pallier, Allan Snyder, and Jason Gallate, for example, recruited a sample of Australian college students to participate in a study of the incubation process in solving convergent thinking tasks. Taking a break and doing something totally different was found to be more effective at enhancing problem solving than either working continuously or working on related types of activities. The researchers concluded that their results were strongly supportive of an incubation effect.

A series of studies involving college students in Amsterdam were designed to investigate the unconscious-thought theory (UTT) of social psychologist Ap Dijksterhuis and his colleagues that was originally proposed in 2006. There are a number of

important components in the theory, but they include the relevance of processes such as incubation, the complementarity of the conscious and the unconscious, and the significance of the unconscious for dealing with complexity in promoting creative thinking. The results of the experimental research were interpreted by the Dijksterhuis team as particularly indicative that previous investigators have underestimated the fundamental role of unconscious processing in creative thought.

Similarly, there is empirical literature that supports the role of intuition in attaining creative insights. Janice Langan-Fox and Debbie Shirley have reviewed issues in the nature and measurement of intuition as well as offering a demonstration of how this process might be defined. They are also optimistic that people can be trained to improve their intuitive abilities. As evidence for the reality of unconscious processing seems to mount, researchers may begin to give up their skepticism about unscientific suppositions. If we are not cautious about spilling the water from the bathtub, we may end up throwing out Archimedes with it. Creativity does not seem to flourish without submission to the unconscious components of the mind.

Glossary

Attention deficit hyperactivity disorder

(ADHD) Symptoms include heightened activity, inattentiveness, and impulsivity.

Convergent thinking Generating one 'correct' answer for a given problem.

Cortical activation Brain activity during any given task.

Creativity A product or an idea that is novel and useful.

Divergent thinking Generating multiple answers for a given problem.

Giftedness Above average intellectual ability.

Underachievement Student's actual performance below his/her ability level.

What Is Underachievement?

Underachievement refers to a level performance that is below an individual's actual ability level. In contrast, overachievement refers to a level of performance that appears to be higher than one would expect given the individual's ability level (although some question whether it is logically possible to achieve above one's potential). Gifted underachievers typically have average or above average academic achievement, yet many do not perform on a par with their abilities. Thus, underachievement can, and should be, differentiated from low achievement. Defining underachievement requires that we are able to measure ability. The most common yardstick for measuring ability is IQ, an easy and widely employed index and significant predictor of future academic performance.

Who Underachieves and Why?

The causes of underachievement can be divided into internal factors such as personality, motivation, gender, ethnicity, and language, and external factors such as family, peer group, teacher, school, and social environment, and culture. Both kinds of causes can lead to underachievement due to low self-confidence, a low ability to persevere, lack of goals, and feelings of inferiority.

Internal Factors

Personality

In 1992, L. J. Emerick showed that gifted underachievers exhibit independence of thought and judgment, willingness to take risks, perseverance, above average ability, creative ability, and an intense love for what they like doing. Gifted students tend to be sensitive to teachers who are critical, rigid, officious, and unsympathetic, as well as to negative social feedback, which can all contribute to emotional conflict and the development of underachievement, as studied by J. R. Whitmore in 1980. Gifted underachievers with emotional problems have relationship problems with teachers, such as demanding behavior, excessive attention seeking, hostility, and rebelliousness, and relationship problems with peers,

including being either intensely competitive or fearful of competition.

Personality inventories of male high ability students show that male high ability dropouts are more assertive, independent, rebellious, cheerful, expressive, frank, and talkative than male high ability nondropouts. S. P. Lajcie and B. M. Shore discussed in 1981 that this might indicate that school pressures for conformity, rather than a lack of interest in school, create potential dropouts. Further, such characteristics can prevent the students from being selected for gifted programs, even if they have superior ability and other talents.

Motivation

Motivation plays an important role in underachievement. Two types of motivation can be distinguished: mastery goals and performance goals motivations. Mastery goals motivation leads to pursuing competency in a chosen field. Students who adopt such goals are self-efficient, persist in the face of difficulty, and are high achievers. Performance goals motivation, on the other hand, leads to hiding of existing ability and being afraid to make mistakes, seeing them as a sign of weakness. Students who adopt these goals tend to be low achievers.

Gender

Boys are more likely to underachieve than girls, with 50% of gifted boys performing below their level of ability. In addition, boys are more likely to drop out of school. However, there is evidence suggesting that there is an equal representation of males and females among underachieving students (e.g., Preckel et al. 2006). The cause for this inconsistency in findings may be that girls' problems and needs are more difficult to identify, and therefore their underachievement is easier to overlook.

Language and ethnicity

English proficiency tends to be associated with greater academic achievement for students whose first language is not English. However, maintenance of their first language is also associated with greater academic achievement because balanced bilingual students tend to perform better academically than monolingual students. Value systems within different communities and cultures have a high impact on academic achievement. For Asian

American and Hispanic American students, strong ethnic, culture, and language retention is associated with successful academic achievement. These students incorporate both cultures into their life experience, and draw resources available to them from either their own or American culture. However, African American students experience the opposite in that ethnic and culture retention tends to be associated with less successful academic achievement. It is more difficult for these students to achieve success if they retain their own cultural norms, in which academic achievement can be considered as "acting white."

External Factors of Underachievement

Poor family relationships and inconsistent standards, peer group, teacher, school, and social environment and culture are external factors that can lead to underachievement.

Parent, peer group, teacher, school, and social environment and culture

In 2001, of the Ph.D.s awarded in the Sciences, 80% were white, 9% were Asian, 4% were African American, 4% were Hispanic, and less than 0.5% were Native American. One of the likely reasons for the persistent underachievement of African American (and some other minority) students is the disproportionate numbers who live in poverty, which often include inadequate learning materials, under-qualified teachers, high administrator and teacher turnover, and overcrowded schools. Other factors include low teacher expectations, lack of access to more rigorous courses, and disproportionate referral to special education. Kozol showed in 2005 that African American students in gifted programs may disengage psychologically because of the lack of diversity in gifted education programs. African American students, and gifted students in particular, do not know that their school counselors or their interactions with counselors are ineffective.

However, African American students attending middle-class schools still do not perform at the level of their white and Asian counterparts. One of the contributing factors is attributed to parents' involvement in their children's education. African American parents tend to have lower academic expectations for their children compared to white parents. For African American students, peer pressure plays a significant role in their underachievement as well.

Comparative studies of ethnic differences in academic achievement tend to label whole groups of African American students as 'underachievers.' Such labeling can damage the way educators perceive African American students' intellectual capabilities and can reinforce the ecological fallacy. Majority and minority students have different reasons for academic achievement and retention in school. Inadequate preparation has been widely assumed to be the cause of most poor academic performance. However, programs that target such causes are not universally successful. Such programs improve academic achievement of majority students, but minority students can still lag behind. Other factors tend to influence minority students' academic performance. Minority students lack minority role models and advisors, who are available to support and advise them and this may be the reason for this disparity.

Teachers' lack of cultural awareness also explains minority students' underachievement, and thus schools need to provide

additional training and educational support to meet the needs of such teachers.

Creativity and Underachievement

Role of Creativity in Underachievement

Creativity is critical for the highest levels of academic achievement. It is a better predictor of outstanding adult accomplishments than measures of intelligence or school grades. In social sciences, for example, creativity explains more variability in performance than reasoning capacity, speed, or memory. In addition, creative thinking is more related to final dissertation marks than to exams or continuous assessment performance.

Neuropsychology of Creativity and Underachievement

Some studies have argued that neural efficiency explains differences in human intelligence – that is, brains may function more efficiently in highly intelligent individuals. (Staudt and Neubauer, 2006)

Highly intelligent individuals use less mental activity (i.e., higher alpha power) than average intelligent ones to perform the same kinds of tasks. Further, there are differences on the neurophysiological level between highly creative individuals compared to less creative ones. Highly creative individuals show less mental activity (i.e., low cortical arousal) than average creative ones while working on open-ended problems. Similarly, highly creative individuals show lower levels of cortical arousal than less creative ones during an inspirational (i.e., thinking of a story) phase but not during an elaboration (i.e., writing down the story) phase (From Staudt and Neubauer in 2006). In 1980, Whitmore showed that underachievers are highly imaginative as well as creative and perform better on holistic or divergent tasks than on analytic or convergent problems. They show a different cortical activation pattern, with greater neural efficiency in frontal cortical areas, compared to achieving students. Differences between achievement and underachievement groups (i.e., underachievers' lower activation) are found in that brain regions which are prominent for creative and divergent problem solving – the anteriorfrontal/frontal cortex. Defocused attention with a lower level of frontal lobe activation and low arousal is important for producing creative ideas. Creative problem solving is generally accompanied by lower levels of cortical arousal. Thus, underachievers might be more creative than achievers because of their lower level of cortical activation in the anteriorfrontal/frontal brain regions (from Staudt and Neubauer in 2006).

Creativity in classroom and at home

See the detailed discussion by K. H. Kim in 2008.

Characteristics of a Creative Student

Creativity can be a gift. However, it is just as true that creativity can be a curse for some students in traditional school environments, where it can lead to underachievement. It has been well documented that highly creative students experience difficulty in traditional school environments. For example, 60% of 400 eminent creative individuals had serious school problems.

Despite strong support for the importance of creativity, classrooms generally do not appear to be creativity-fostering places, primarily due to the biases of teachers and traditional classroom organization, lack of meaningful curriculum differentiation, and lack of originality in classroom-based enhancement efforts.

When highly creative students are forced into traditional school environments, they may become troublesome to teachers and disruptive in the classroom. They may resent the constraining structure of the classroom, excessive rules and regulations, and the press for the conformity. They avoid unpleasant academic tasks and interactions with teachers or peers and can become troublemakers, which can in turn negatively affect the classroom environment for others. Eventually, these creative individuals can develop into underachievers.

Not surprisingly, teachers prefer students who are achievers and teacher-pleasers, rather than disruptive or unconventional creative students. Teachers frequently perceive creative student behaviors as 'misbehaviors.' Creative students often display characteristics disliked by teachers such as hyperactivity, argumentativeness, selfishness, stubbornness, and independence. Many of the traits associated with attention deficit hyperactivity disorder (ADHD) also seem to be present in children who have been identified as gifted, talented, or creative. For example, compared with students who can focus attention easily, students with ADHD gather and use more diverse, non-verbal, and poorly focused information, and show higher figural creativity. In fact, teachers may mistake a highly creative student who is energetic and unconventional as having ADHD. This disconnection between teacher's preferences and highly creative students may lead to a discrepancy between classroom expectations and a creative student's educational needs. Therefore, educators are encouraged to be mindful of the creative talent in young people by recognizing and nurturing it to reduce underachievement, the school dropout rate, and other negative spin-offs.

Teachers' Preferences and Perceptions

Teachers tend to prefer students who conform to their requests, and exhibit socially acceptable behaviors. When questioned about the characteristics of their ideal student, teachers list easily manageable behavior and logical thinking as some of the most desirable traits. G. A. Davis and S. B. Rimm discussed in 1994 that teachers tend to prefer students with a high IQ rather than students who are both highly creative and highly intelligent. Some teachers see creative children as a source of interference and disruption. In fact, teachers' judgment of their favorite students is negatively related with creativity.

Although teachers agree with the abstract goal of fostering and encouraging creativity in children, their in-class demeanor and nonverbal behaviors appears to be antithetical to such a goal. For example, teachers report that they value qualities such as curiosity and independent thinking in their students, but students report that their teachers' behavior suggests that they value obedience and devalue asking questions and self-sufficiency. In fact, the work on teachers' views of the creative personality generally has been interpreted by Davis and Rimm as indicating that creative children in the classroom will be ignored or even punished.

Many teachers perceive highly creative students as nonconformists, easily distracted, and experiencing obstacles in fulfilling their academic obligations. E. P. Torrance and H. T. Safter discussed in 1999 that most teachers show a general lack of understanding about the nature of creativity and the characteristics of creative students. They most often associate creativity with artistic ability. Teachers often confuse characteristics of gifted high achievers with creative characteristics. When teachers are asked to think of a creative student, they frequently describe high achievers who possess some creative traits. However, intelligent people produce high quality products, but not necessarily novel ones. Therefore, if traits of creativity are confused with traits of high intelligence, a large majority of creative students will be overlooked.

Funding limitations may lead to situations where teachers are overloaded by class sizes. Naturally teachers seem to gravitate to students that are easier to handle, respectful, not disruptive, follow along in class, and accept their teaching unquestioningly. This may lead to rigid classrooms, which discourage new and unique ideas and demand obedience, rote memorization, and conformity. Ultimately, this combination can stifle creativity and lead to underachievement of highly creativity students.

Structure and Conformity

Teachers who prefer conformity are frustrated by many characteristics of highly creative students. Highly creative children, especially highly creative boys, have a reputation for having wild or silly ideas. After a child gains a reputation for being silly, it is difficult for teachers and classmates to see good ideas as anything but silly. This is exemplified by a third-grade teacher who had emphasized conformity to behavioral norms so much that she could not recognize the achievements of a certain highly creative student, even though this student had learned more than any of her other students (from E. P. Torrance in 2000).

As gifted students move forward in school, their desire to conform, fit in, and be accepted by teachers and peers causes many of them to disavow their uniqueness (as discussed by Torrance and Safter). A teacher's desire for conformity can also drive students to nonconformity. Nonconformity can become a drive in highly creative individuals with exceptional mental abilities, whose natural thought processes can lead to exploring concepts and methods that diverge greatly from the norm, especially when they are faced with pressure to conform.

Parental Influences

Parental attitudes can impact a child's creativity in a similar manner to teachers' attitudes. Parents of highly intelligent and highly creative children emphasize different characteristics when asked to describe their children. Parents of intelligent children tend to describe their children as polite and studious. Parents of creative children, on the other hand, tend to describe their children as enthusiastic, open to experience, and having a lot of interests. There is a strong relationship between preschool children's creativity test scores and their mothers' chaotic or rigid family style.

Parents may feel threatened when their highly creative children express their creativity. Some of the questioning, experimenting, and wild ideas can be annoying. Creative behavior may be interpreted as aggressive or even hostile, and it becomes just that if ideas and questions are rejected. Children who show creative activity consciously ask annoying questions and challenge the *status quo*. In response, parents may react by punishing this exploration of alternatives and discouraging their child's abilities.

Creativity and Society

Sensitivity, Risk-Taking and Socialization

Highly creative students face social difficulties due to their unique personality characteristics and needs which may not be experienced by other students. What distinguishes creative adolescents from their less creative counterparts is their greater independence and rebelliousness, deeper feelings and fuller range of emotional expression. Creative people are highly sensitive and are easily disturbed. They integrate feminine and masculine characteristics more fully, and demonstrate higher originality, imagination, and divergent thinking. In addition, compared to students with high IQ, highly creative students exhibit much higher degrees of humor. They enjoy taking risks and being in unusual situations. Torrance showed in 2000 that if a student asks an unusual question or advances a new idea, the student runs a risk of ridicule by classmates and by the teacher. This risk of ridicule may tend to discourage risk-taking, which is important in the acquisition of skills and knowledge.

Evidence of the anti-creativity effects of childhood socialization can be described by a 'fourth grade slump,' which is a drop in creativity test scores after the third grade. The observed drop may be caused by peer pressure and demands for conformity in the classroom. In addition to creativity, curiosity declines by fourth grade among gifted students.

Gender Roles

Gender role expectations may have an impact on underachievement and creativity. Creative individuals seem to diverge from sex norms because both sensitivity, which is traditionally a feminine virtue, and independence, which is considered to be a masculine virtue, are essential for creativity. Torrance indicated in 2004 that some students may sacrifice their creativity in order to maintain their masculinity or their femininity, which can lead to emotional issues and other problems for highly creative students. Teachers who are sensitive to gender issues among their students are in a position to soften the negative impact of sex-role stereotyping.

Suppression of Creativity and Emotional Problems

An entirely different problem may manifest when highly creative children suppress their creativity and become overly conforming and obedient. They are likely to grow up with a lack of confidence in their own thinking and be overly dependent upon others in making decisions. They fail to develop because

they have not been provided situations in which it is safe to practice without negative evaluation. The psychological dangers are severe if creative needs are strong and suppression is severe or prolonged. Torrance showed that in such cases, tension is likely to be overwhelming and psychosis can result. Creative people derive meaning from expressing their creativity, and denying them the opportunity to express their creativity can lead to numerous problems. Students may succumb to peer pressure and conformity, which can lead to the denial and inhibition of their creative ability. It may create personal tension, feelings of social stress, estrangement, and eventually may even cause a breakdown. Ultimately, such stifling of creativity affects creative students' quality of life.

Loneliness is a serious problem for highly creative students, especially if they do not have anybody who can listen to their original ideas without criticism. However, this is often the reality for creative children – they find themselves isolated from, and even teased by, peers and sometimes go through school unnoticed. Because creativity involves independence of mind, nonconformity to group pressures, or breaking out of the mold, highly creative students can experience problems of adjustment. They must either repress their creativity or learn to cope with the tensions that arise from being different. Repression of creative needs can lead to personality breakdown, while expression of those needs leads to loneliness, conflicts, and other problems of adjustment (see Torrance in 1994).

Unrecognized Creativity

Many unrecognized, creatively gifted, students are somewhat shy or nonassertive in the classroom. Some are children who teachers report to be in frequent conflict with classmates. The disruptive child usually consumes a lot of teacher attention, but does not show exceptional academic achievement or potential. Some students become highly creative when they enter special programs for the gifted, but most of them have learned to suppress creative impulses or had not yet discovered them. This means that such students may only become aware of their potential for creative productivity and the intrinsic rewards derived from the act of creating, once they are placed in an environment that encourages creativity.

Students' creativity can contribute to their underachievement as indicated by the real world measure of grades. It appears that some classroom interactions discriminate against creative ability such that students who try to use this ability achieve less well. Students with only high IQ, for example, achieve more than students with only high creativity scores, and students with combined high intellectual and creative skills do equally well on achievement measures, but have significantly lower school grades. In addition, those students who use their creative ability in the classrooms achieve less well than those who use their intellectual skills.

Creativity and Behavior Problems

Students with behavioral problems obtain statistically significantly higher scores on flexibility and originality measures. For example, youth delinquents from a Juvenile Justice System showed that approximately 18% of those screened turned out

to be gifted in some way. It is possible that these students' creative personality played a role in their problems.

Discrimination against creativity may go as far as to force creative students to drop out of high school or college. In fact, dropouts outperform nondropouts on creativity tests. Similarly, high school underachievers are found to be more creative compared with a group of normal achievers. Evidence suggests that creativity is related to school offenses. Popularity and misbehavior appear to be most predicted by creativity scores, whereas fluency and elaboration contribute more than other creativity subtests to the misbehavior correlation.

What Can We Do About It?

The characteristics of gifted underachievers are similar to the characteristics of highly creative underachievers. The same models and procedures can be used for mentoring and fostering highly creative and gifted underachieving students. Once creative students are in an environment that meets their needs, they perform much better, although reversing the underachievement may take a long time and be difficult.

Students' different weaknesses or difficulties and strengths can be hidden behind similar academic achievements, regardless of underachievement or overachievement. Thus, before educators make a diagnosis to design suitable and differentiated instruction for each student, identifying strengths and explicitly building on them is as important as carefully identifying each student's difficulties or weaknesses.

Less Restrictive and Less Evaluative Environments

Creative children's underachievement is minimized when school settings are least restrictive. The best learning environment for creative students allows them to move around and be physically active as much as possible, rather than being confined to their seats. Creative students also seem to thrive in challenging environments because without challenges creative students become frustrated and may lose interest in an activity. One of the primary problems is the failure of the school to give creative students challenging tasks in a less restrictive setting. Torrance showed in 2000 that misbehavior can often be seen as a reaction to the unchallenging, boring, and reproductive tasks given to highly creative students in restrictive school settings.

Further, students' creativity is fostered when teachers minimize the use of assessments in making social comparisons. When students focus on self-improvement, they are more likely to take risks, seek out challenges, and persevere in the face of difficulty. For students to be willing to express their creativity, they must feel that their ideas, especially those who are unconventional, are welcome in the classroom.

Play and Fun

Abundant play facilitates maturation of the frontal lobe inhibitory skills that gradually come to regulate children's impulsive primary-process emotional urges. Many parents and school systems neglect play needs, assuming that treating children like little adults facilitates the construction of well-conducted

citizens. However, human socialization occurs when children's brains are allowed to learn and develop in culturally rich, mind-supporting environments, including those that support a variety of self-generated social activities encompassed by the concept of 'natural play.'

If creatively gifted children are engaged in an academic activity that is fun and playful, they will become more motivated to learn and grow to fulfill their potential. Therefore, teachers and parents must continuously bring fun as the most important attribute to creative children's learning. Teachers need to incorporate play and fun fully into gifted education. Highly creative students should be encouraged to have pride in their own work instead of making external rewards a goal. Intrinsic motivation should be modeled by intrinsically motivated adults. Children should be shown the value of being creative for creativity sake, rather than for competing with their peers. Creative students should be given a choice of which activities to pursue, and on how they follow such activities. And again, play, fun, and imagination should be emphasized as much as possible. Teachers, parents, and families can help creatively gifted students by allowing them to pursue topics of strong interest. Allowing students to explore a variety of topics and skills and then giving them the time to pursue some in depth is a way of reversing underachievement. Creative students seek more challenge than average students. They prefer tasks they are intensely interested in, and would rather work independently than within a group. Creative students value freedom of choice: They become more motivated and engaged if given freedom to choose activities rather than receiving direction on specific pursuits. The freedom to pursue topics of strong interest often results in high levels of achievement.

Creative Teachers

Teachers who foster creativity allow choice of topics, welcome unorthodox views, interact with their students outside of class, and conduct classes in a more informal manner. In addition, teachers who make a difference help students fall in love with a subject so intensely that it becomes the center of the student's future career image. This future-image and passion is the best predictor of future creative achievement (see the 1994 book by Torrance).

Adult mentorship and understanding can have a strong impact because creative students are natural outsiders who often flounder in attempts at meeting seemingly contradictory needs. Teachers and counselors must help creative students learn to tolerate and understand their separateness, and they must help them find someone with whom they can communicate. Creative students need to develop and maintain self-confidence in their abilities to go beyond the limits of the known and familiar, and to endure in the face of risking failure to truly excel. Adults play an essential role in supporting creative students in their pursuits.

Highly creative teachers tend to have overachieving creative students, whereas less creative teachers have more underachieving creative students. The goal of guidance is not to promote individuality and creativity, but to encourage a healthy balance of individuality, creativity, and conformity. If students achieve a balance between creativity and conformity, they can enhance one another.

Teacher Training

Teacher training in creativity and nonconformity is one highly recommended change. Teacher training has an impact on teachers' conformist attitudes and interactions with students. Training in creativity influences teacher attitudes toward highly creative gifted students and training reduces sex role stereotyping. Teachers who have a gifted education background respond differently to gifted students when compared to preservice teachers or teachers without a gifted education background. Unfortunately, many elementary school teachers tend to be politically conservative and conforming. These teachers have a difficult time with students who are nonconforming and speak their mind. Rather, they prefer students who are submissive and conform to teacher's rules. Thus, it is important that teachers are trained on what types of behaviors are associated with creativity and giftedness, and do not ignore or punish such behaviors. If teachers are exposed to a sufficient range of information about individual gifted, talented, or creative students, they will be sensitive to the students' multiple intelligences and will also be less likely to respond to students' gender, social class, and racial information.

Voice and Choice

All students, but creative students in particular, have a strong need for voice and choice. Creative students need the option of voice to express their creative ideas, and choice to pursue those ideas. Stifling creative students' voice may cause them to withdraw or to rebel. Conversely, they will explore their own possibilities and strengths, and develop their own learning style when voice is given to them. Classroom meetings empower students, giving them some control over their environment and a chance to voice and process diverging viewpoints. Teachers who provide some open-ended assignments or open-ended components find success in bringing out the creative

potential in their students. Finally, concentration on meaning rather than rote memorization will benefit a highly creative student.

VINCENT VAN GOGH was an artist for 10 years, from 1880 to 1890. As a mature artist, he is known for his distinctive style of undulating lines and bold colors. During his mature phase he was capable of executing works in a rapid fashion, sometimes up to three a day spending less than an hour on each. He spent 9 years of deliberate repetition to evolve his competencies to a level where he could execute rapidly and automatically. In spite of his diverse ways of behaving, van Gogh possessed a remarkable unity of mind and spirit, as can be seen in the many letters—more than 700 of them—that he wrote over a period of 20 years.

Childhood (1853–1876)

On March 30, 1852, Anna Cornelia Carbentus van Gogh, 33 years old, gave birth to her first child. It was stillborn. Christened Vincent Wilem van Gogh was buried in the graveyard of the local church. Exactly one year later, on March 30, 1853, she gave birth to a healthy male, and he too was named Vincent. As a schoolchild, the young Vincent walked past the local cemetery in which a gravestone bore his name and birthday. Vincent's father, Theodorus van Gogh, was a Protestant pastor at the village of Groot Zundert in North Brabant in the south of Holland, near the Belgian border. Vincent van Gogh was the firstborn to Anna and Theodorus. They had five more children: Anna Cornelia, Theodorus, Elizabeth Huberta, Cornelis Vincent, and Wilhelmiën Jacoba. During his adult years, Vincent would remain close to Wilhelmiën, his youngest sister, and extremely close to his younger brother and staunch supporter, Theo. The collaboration between Theo and Vincent remains one of the most remarkable interactions in the history of art, and it is difficult to imagine Vincent's creativity without

the support of, and feedback from, his younger brother. Van Gogh came from a relatively unremarkable background. His ancestors had been art dealers, consuls, goldsmiths, preachers, and there had been a sculptor. Other than art dealership, Vincent's family showed no propensity for the type of creativity demonstrated in his work.

Johanna Bonger, Vincent van Gogh's sister-in-law, reported that, as a child, van Gogh had a difficult temper, was often troublesome, and was strongly self-willed. She noted he had a great love for animals and flowers and delighted in collecting things. There was, however, during his childhood, no indication that young Vincent was precocious nor had an unusual talent for art. On August 1, 1866, van Gogh was apprenticed to a branch of the prominent Paris art dealers Goupil & Cie at The Hague. He was exposed to various works of art and, under the supervision of H. G. Tersteeg, assisted in the sale of paintings, photographs, engravings, lithographs, and reproductions. Van Gogh worked at this apprenticeship until he was fired in 1876 for conducting himself in a manner antithetical to the firm's interests; for one, he would commonly and inappropriately discuss the merits of the works of art with customers, and he frequently talked them out of sales.

Searching (1876–1880)

From 1876 until 1880, when van Gogh was 23 to 27 years old, he engaged in multiple activities in the pursuit of a meaningful career. He was variously a teacher, a book dealer, and a minister.

Vincent van Gogh, at the age of 23, four years prior to his decision to become an artist, was an intelligent, enthusiastic book dealer working in Dordrecht, Holland. A fellow lodger wrote of him:

He was a singular man with a singular appearance into the bargain. He was well made, and had reddish hair which stood up on end; his face was homely and covered with freckles, but changes and brightened wonderfully when he warmed into enthusiasm, which happened often enough. Van Gogh proved laughter repeatedly by his attitude and behavior—for everything he did and thought and felt, and his way of living, was different from that of others of his age.

In May 1877 van Gogh left Dordrecht and his job as a book vendor and went north within Holland to Amsterdam. There he refined his idea of working. Sensing that he was impulsive, he recognized that he needed to exercise patience and discipline and wrote to his brother:

I have a lot of work to do and it is not very easy, but patience will help me through. I hope to remember the ivy "which stealth on

though he wears no wings"; as the ivy creeps along the walls, so the pen must crawl over the paper.

He was referring to the writing he was required to do for his theological studies—he was preparing for an exam he needed to pass for entrance into a university. Van Gogh outlined his intention to proceed with his theological studies in an ongoing, logical manner and expressed his belief that there were certain commonalities between studying religion and painting: "[C]oing on step by step . . . must lead to a good result. . . . But it takes time. . . . A great deal of study is needed for the work of men like father [a pastor] . . . just as for painting."

Van Gogh started as an artist late. During 1878 to 1880, while he had his job as a lay minister in Belgium, he sketched the miners who made up his congregation. At this time he wrote:

I still can find no better definition of the word art than this, . . . art is man added to nature . . . — nature, reality, truth, but with a significance, a conception, a character, which the artist brings out in it, and to which he gives expression . . . which he disentangles, sets free and interprets.

He recognized in June 1879 that artistic development involves the conscious quest for novelty, and in this regard wrote, "the artist has put things in a new light . . . all things have become new."

In 1879, van Gogh secured a position as a lay minister with miners in Belgium. As was his custom, he threw himself into this job, giving away his belongings, living on bread and water, and taking sick miners into his own home. His church superiors reprimanded him for his excessive zeal and ultimately he was dismissed.

While a minister, he sketched the miners, and it was after his dismissal that he went through a period of existential crisis during which he questioned the direction of his life's work. After several months of soul searching, the answer emerged clearly, and in June 1879 he noted in a letter to his brother Theo that an artist's vocation was a sublime, admirable one. Further, he wrote passionately of his intention to engage in a quest for a distinct style and his belief that a concept for a work precedes the execution of a work. Van Gogh worked as a lay minister with miners. They provided an image for him regarding positive character traits and productive ways of working: "[T]hey are intelligent and quick at their difficult work," he wrote in 1879, "brave and frank." (New York Graphic Society, Letter 129, originally April 1879). He saw his work proceeding by quick actions and slow progress, like the miners with whom he so obviously identified:

[T]hey are short but square-shouldered, with melancholy deep-set eyes. They are skillful at many things, and work terribly hard. They have a nervous temperament — I do not mean weak, but very sensitive. They have an innate, deep-rooted hatred and a strong mistrust of anyone who is domineering. With miners one must have a miner's character and temperament, and no pretentious pride or mastery, or one will never get along with them or gain their confidence.

It was during July 1880, at the age of 27, after being fired from his position as minister, that he wrote to Theo of his intention to become an artist. This begins a collaboration between Vincent and his brother that will last for 10 years

until Vincent's death. Theo agreed to send Vincent a monthly allowance in exchange for his artworks.

Getting Started (1879–1882)

During the summer of 1880, van Gogh experienced a philosophical and spiritual crisis, and after a period of intense rumination he decided to devote his life to being an artist. At the beginning of his tenure as an artist, he outlined his idea of art:

[A]rt is man added to nature . . . nature, reality, truth, but with a significance, a conception, a character, which the artist brings out in it, and to which he gives expression . . . which he disentangles, sets free and interprets.

In October of 1880 Vincent moved to Brussels to begin art studies; he read books on art and perspective and studied copies from prints, especially Millet. His decision to become an artist was preceded by certain ideas about work: that effective results require commitment and hard work, that to do something with fluency and ease one must spend a great amount of time in preparation, that the miner served as a metaphor for the quick execution of one's actions. Earlier, van Gogh tried executing his sketches in a quick manner. "I am sending you a hasty sketch," he wrote to his brother, "but I . . . need to study the . . . masters."

His interest in hard work persisted, and on September 24, 1880, he wrote to Theo that "I am in a rage of work, though for the moment it does not produce very brilliant results." In the same letter he noted the best work is "conscientiously done, with the evident intention of portraying the truth without any straining after effect."

In September 1880, van Gogh wrote of a metaphor that was to guide his work over the succeeding several months: a weaver at a loom. The effective artist and weaver, according to van Gogh, both learned their craft so that the work could be executed unconsciously, with ease and at a cautious, steady, deliberate pace. He wrote, "with his dreamy air, somewhat absent-minded, almost a somnambulist—that is the weaver." During this time, van Gogh rendered more than 36 pictures of weavers at looms. He varied the positions and the lighting, each time seeking the best arrangement of forms.

During his seminal attempts at art in July 1880, van Gogh acknowledged the need to construct and reconstruct a product by first beginning with an initial sketch or rough draft, developing it into a more refined sketch, and again reforming it into a completed work. He wrote, "as the rough draft becomes a sketch, and the sketch becomes a picture—little by little, by working seriously on it, by pondering over the idea, vague at first, over the thought that was fleeting and passing till it gets fixed."

In 1881 he returned to his parents' home in Etten to join Theo and an artist friend Van Rappard. After a brief stay at Etten, he moved to The Hague in 1881 to study with his well-known artist cousin Anton Mauve. He set up his own studio at The Hague, and he met and lived with a reformed prostitute named Clasina Hoornik, nicknamed Sien by him, and her two children. During August of 1881, after concentrating for several months on drawing and multiple media (e.g., charcoal and watercolor), he tried his hand at oil painting for the first time.

After some seminal attempts, he decided that his skills were too poorly developed for this demanding medium and returned to the basics, which meant drawing and related media.

During August 1882, he made a second attempt at oil painting after a year of drawing. Again he decided that he was not yet ready for the demands of painting, and he returned to drawing.

Van Gogh's early experimentations with oil painting led to a tube-squeezing insight—the realization that squeezing the paint directly from the tubes opened up possibilities for new effects. It happened when he was painting out-of-doors. He wrote to Theo:

It struck me how sturdily those little stems were rooted in the ground. I began painting them with a brush, but the surface was so heavily covered, a brush stroke was lost in it—then I squeezed the roots and trunks in from the tube, and molded it a little with the brush. Yes—now they stand there rising from the ground, strongly rooted to it.

As important as the tube-squeezing insight is to van Gogh's mature style, he elected to shelve it, along with all efforts at oil painting, and focused his efforts on drawing and related media, such as pencil drawing and lithography. He believed that oil painting was the most demanding of all media, and to do justice to its demands he believed that he needed to develop his skills for other tasks, such as drawing. "Drawing is the backbone of painting" he was fond of saying. He realized the tube-squeezing insight was valuable. But he had no overall mental structure for style to which it could be adapted. Put aside temporarily, he reactivated it when other mental structures evolved to more complex levels that were able to accommodate the innovative tubesqueezing insight. The tube-squeezing insight foremost demonstrates that van Gogh's creativity was a combination of long periods of planful work along with spontaneous play and chance events.

Van Gogh went to The Hague, Holland, in December 1881 and left in September 1883. During this 20-month period he wrote approximately one-quarter of his total letters, he redefined his ideas about models, he clarified his notions of love through his romance with Clasina Hoornik, and he rendered a total of 357 existing works, done in multiple media, including pencil, charcoal, chalk, ink, lithography, watercolor, and oil; only 7% of this output was oil painting.

Drawing dominated van Gogh's activities during the first two years of his tenure as an artist. In August 1882 he wrote, "But I have attached great value to drawing and will continue to, because it is the backbone of painting, the skeleton that supports all the rest." He did not address painting seriously until his third and fourth years as an artist; he was very planful to ensure that his drawing skills were acceptable to him before he undertook his adventures at oil painting. He mentioned that "before I began to paint, I had been drawing so much and studied perspective in order to build up the composition of the thing I saw."

When van Gogh began his activities as an artist in 1880, he brought to that experience a wide range of knowledge from previous enterprises, such as knowledge of literature, religion, and teaching. Once firmly committed to art, he subdivided that enterprise into various tasks and purposes, a notion he addressed in the following passage written during October 1884:

I have bought a very beautiful book on anatomy, *Anatomy for Artists* by John Marshall. . . . I have also what they use at l'Ecole des Beaux-Arts, and what they use in Antwerp. . . . The key to many things is the thorough knowledge of the human body. . . . Besides, I am quite sure that color, that chiaroscuro, that perspective, that tone and that drawing, in short, everything has fixed laws which one must and can study, like chemistry or algebra. This is far from being the easiest view of things, and one who says, "Oh, one must know it all instinctively," takes it very easy indeed. If that were enough! But it isn't enough, for even if one knows ever so much by instinct, that is just reason to try so hard to pass from instinct to reason.

Van Gogh was addressing multiple issues and multiple activities. Not all of the ideas expressed, such as approaching art like an algebraic equation, were used by him later in the form found here. But leading himself down certain pathways, from which he may retreated or abandoned completely, served a constructive function of having a pattern to reconstruct in his own manner. An initial pattern for reconstruction was provided during this early phase of development by his adoption of classical placements and poses of models resulting from academic influences, from the Holland experiences, and art instruction books.

After 20 months at The Hague, van Gogh decided to move to Drenthe, north within Holland. He left The Hague with vastly improved skills and greatly refined ideas about his working and during his last summer there he noted, "Last year I repeatedly tried to paint figure studies, but the way they turned out made me desperate. . . . [N]ow there is nothing that keeps me from carrying it out, because drawing comes so much more easily to me than last year."

He left The Hague a much better and more confident artist, but still recognized that he had a long way to go to develop an individualized style. "I know that I'll have to make many studies," he told his brother Theo, "therefore a great deal of painting must be done this year, and then there will come more light."

Van Gogh The Painter (1883–1888)

Experimenting with the interaction between oil and various media was an early preoccupation for van Gogh because he wanted to test the waters. His plan was to eventually tackle and conquer the demanding medium of oil painting on canvas and toward this end he wanted to develop a finely tuned skill for understanding the properties and attributes of oil interacting with other substances. This strategy as part of his overall plan did not go wasted.

Ever looking for the unusual interaction of materials and media, during the spring of 1883, van Gogh rendered a group of drawings that involved the experimentation of the interaction between printer's ink and various media. In regard to this he wrote:

But now about the drawings. I have done a few with printer's ink, and this week I made some experiments in mixing that printer's ink with white. I found out that it can be mixed in two ways—that is, with the white from the tubes of oil paint and, probably even better, with the ordinary powder zinc with white which can be obtained at any drugstore; it must be diluted with turpentine, which doesn't soak into this paper or cause spots on the black like oil does, because it dries

quickly and disappears. One gets much stronger effects working with printer's ink than ordinary ink.

Some of van Gogh's ideas regarding experimentation came from other artists. During May 1882 he wrote, "One can do great things with charcoal soaked in oil, I have seen Weissenbruch do it; the oil fixes the charcoal and at the same time the black becomes warmer and deeper."

In September 1883 van Gogh decided to leave The Hague and go to Drenthe, in northern Holland, for a new "field of action," in his words. He and Sien decided to break up. She returned to prostitution and several years later committed suicide. The breakup caused van Gogh considerable pain, and at Drenthe he wrote, "I often think with melancholy of the woman." Although his best-known works are paintings, van Gogh proclaimed in June 1883 his early experimentation with charcoal and ink: "[M]y dislike for working with charcoal is disappearing more every day. One reason for this is that I have found a way to fix the charcoal and then work it, for instance, with printer's ink."

Van Gogh engaged in a process of associating and consolidating previously unrelated elements and synthesizing them into a broad, purposeful plan. Van Gogh's broad plan throughout his production was to construct an effective artistic style, based on a notion of action and undulation. He wrote, "I tried to put sentiment into the landscape, and to convey the convulsive, passionate clinging . . . yet . . . half torn quality of the tree, to capture the struggle for life, to faithful to nature."

Van Gogh very strongly believed that a skill for drawing must be established before advancing to painting. Further, while drawing, he kept in mind the use of drawing as a springboard for skilled painting. In the same letter he wrote, "Though *The Roots* is only a pencil drawing, I have brushed it in with lead pencil and scrapped it off again, as would if I were painting." Scraping a pencil drawing functioned as a cognitive strategy to bridge the skills of drawing and painting. Scraping an oil painting is a method of revision; the artist removes parts that are unsatisfactorily rendered. One method of revision employed by van Gogh was scraping-and-repainting. In the following passage he describes how he scraped off areas of paint when he was dissatisfied with an effect. He would then repaint the area and, if still not satisfied, scrape and repaint until his intention as achieved. Over time, van Gogh became extremely competent at examining, analyzing, criticizing, and revising his efforts; this is the type of thinking we can call "self-regulation." He established a finely tuned sense of which efforts were poor and which were excellent.

If I have now painted so many studies in a short time, it is because I work hard, literally working all day, scarcely taking time even to eat or drink. There are little figures in several of the studies. I also worked on a large one and have scraped it off twice, which you perhaps have thought too rash if you had seen the effect; but it was not impatience, it was because I feel I can do better by grinding and trying, and I absolutely want to succeed in doing better, however much time, however much trouble it may cost.

Revision was important to the van Gogh's creative process. He utilized other types of revision in addition to painting-scraping-repainting. Not only would he alter an individual work in an effort to improve its structure, but he would

revise a concept by rendering a series of works. His group of sunflower paintings provides an example. He began by painting solitary flowers; then, work by work, introduced two, then three, and so on, until he worked his way toward the magnificent bouquets well known to the public. Revision, thus, is an important aspect of creativity. Effective creators are adept at generating seminal ideas and evolving them into coherent systems.

Van Gogh's use of his studio was an important aspect of his working. He would sketch his subject matter on location, making note of the source of lighting. He wrote, "I enclose a little sketch which I made in the soup kitchen. They sell the soup in a large passage where the light falls from above, through a door to the right."

He would take his initial sketch and use it as a guide to set up the same scene in his studio, positioning models and, by a careful manipulation of the light coming in through the windows (covering some of the windows with curtains), re-create the original scene that was recalled from the sketch. Sketching on location has its advantages and disadvantages. One disadvantage is that the scene is fleeting; people are moving about, and, for the artist, getting accurate details is difficult. A re-creation of the scene in his studio, based on the initial sketch, allowed van Gogh the luxury of attention to details and to careful drawing that was difficult to achieve on location. Further, as can be seen in the following passage, van Gogh drew a backdrop to his models in the studio based on his on-location sketch. He set up the scene in his studio much like a stage manager would arrange the props and actors for a play. He wrote:

Now I tried to find that same effect in the studio. In the background I put a white screen, and on that I drew the hatch, according to its real position and measurements; I closed the farthest window at the bottom, so that the light falls from P, exactly as in the place itself.

The *P* he refers to is a spot from which the light fell on his models in the studio, replicating the source of light in the original scene. His studio was a transitional arena for him to mediate the source of inspiration and the final work. He added, "You see, when I have the models posing there, I get exactly the same effect as in the real soup kitchen."

Van Gogh consistently made a distinction between *sketches* and *drawings*. A sketch was spontaneous, incomplete, the starting point for further work; a drawing was a finished product. Recreating scenes in his studio allowed him the opportunity to evolve an initial sketch from an ill-defined, seminal idea to a completed drawing. He wrote to Theo, "[T]omorrow I'll have the house filled of people . . . from the neighborhood, and . . . these persons . . . will pose for the drawing of which this is the first rough sketch."

Typical of his attitude toward working with multiple media and executing rapidly during his period at The Hague is the ideas expressed in the following passage, written to his brother Theo during February 1883:

But I shall have to put up with many more failures, for I believe that in water color much depends on a great dexterity and quickness of touch. One must work in it before it is dry to get harmony, and one hasn't much time for reflection then. So the principal thing is not finishing each one separately, no, one must put down those twenty or thirty heads rapidly, one after the other. Here follow a few curious

sayings about water colors: "L'aquarelle est quelque chose de diabolique"; and the other is by Whistler, who said, "Yes, I did that in two hours, but I studied for years to be able to accomplish this in two hours."

This passage highlights several characteristics about van Gogh's ideas for working at that time, 1883. First, he was heavily influenced by James Abbott McNeil Whistler's notion that rapid execution required years of preparation: "Yes, I did that in two hours, but I studied for years to be able to accomplish this in two hours."

Whistler, in the mid 1800s, took the well-known art critic John Ruskin to court. Ruskin had accused Whistler of "flinging a pot of paint into the public's face," meaning that the artist had quickly dashed off his works and was trying to pass them off as serious works of art. Whistler, on the stand, pointed out to the court that although he executed the works in a spontaneous, quickly brushed manner, he spent a long time in pre-execution training. Van Gogh was very impressed by Whistler's notion that the appearance of spontaneity in art requires arduous preparation. Second, van Gogh was unafraid of failure and of taking risks—and actually thought that failure was necessary as a source of growth. Van Gogh felt that in order to learn, one fails, and then he exclaimed, "Forward—and what the devil do I care if I fail—if I fail, then I'll try again." Third, van Gogh expressed the belief that reflection is most effective when it precedes and follows a work. An artist needs to consider what is going to be done, but also needs to consider what *has* been done so he can decide what to do next. For van Gogh, each work in a group (such as the 36 weavers) provided inspiration and correction for the next. Fourth, van Gogh believed that a rapidly executed work (based on careful preparation) was aesthetically more expressive and pleasing than one that was not.

Vincent van Gogh loved experimentation. In his quest for a novel artistic style, for example, he used lithographic crayon to do drawings, a use that this type of greasy crayon was not specifically designed for, and he included bread crumbs into the drawings to experiment with various values of tone. As he related to his brother:

I wrote to Rappard about the crayon yesterday, because I had to write him about various things concerning lithography; and as I wanted to send him a few sketches done with it, I used it for some drawings of our baby, in different positions, and I found it is very well suited to sketching, too. One can bring in demitones by means of bread crumbs.

Van Gogh left The Hague in September 1883 and arrived in Paris 2½ years later. In between he stayed at Drenthe (September to November 1883), Nuenen (December 1883 to November 1885), and Antwerp (November 1885 to February 1886).

During this time he continued working by the principles and ideas established at The Hague, and the culminating work of this period was his monumental *Potato Eaters*, the depiction of peasants sitting about a table having dinner, for which he executed more than 150 studies of heads before rendering the final painting.

Van Gogh moved to Paris to live with his brother Theo in March 1886. Since he was living with his brother, he had no need to write, hence, there is little correspondence during this 2-year period.

Maturity As An Artist (1888–1890)

Van Gogh decided in 1888 to leave Paris and go to Arles, a small, picturesque town in the south of France, to discover, in his words, "a new light." During his stay at Arles, from February 1888 to May 1889, van Gogh achieved full maturity as an artist and established his own individualized style. He also spent a 2-month period sharing housing and collaborating with Paul Gauguin. During this time, he had the first of seven "attacks" of mental illness during which he severed an artery in his ear; he did not cut off his ear as some people have incorrectly described the famous incident.

More than ever he accelerated his efforts and intentions to work quickly, execute rapidly, and at the same time render effective figures. Van Gogh was ever the one to isolate problems of execution and then work on them tirelessly until he arrived at a solution. He wrote:

Oh! someday I must manage to do a figure in a few strokes. That will keep me busy all winter. Once I can do that, I shall be able to do people strolling on the boulevards, in the street, and heaps of new subjects. While I have been writing this letter I have drawn about a dozen. I am on the track of it, but it is very complicated because what I am after is that in a few strokes the figure of a man, a woman, a child, a horse, a dog, shall have a head, a body, legs, all in the right proportion.

By 1888 van Gogh had progressed to the point that he would execute a painting in one sitting. "More than once," he wrote, "I have done a size 30 canvas in one day, but then I did not stir from the spot from morning till sunset except to eat a morsel."

Van Gogh worked rapidly, and when his efforts did not please him he would scrape off and repaint sections. In addition, he would add finishing touches, when appropriate, after a painting would dry. Van Gogh worked rapidly and revised by scraping and adding details after drying. A close look at *Starry Night* (at The Museum of Modern Art in New York City) reveals that some of the stars in the sky were painted as part of the original conception and that some were added after the painting had dried. Similarly, if you examine *Pipe with Chair* (executed at Arles), it is evident that the pipe and other details were added after the painting dried.

During September 1888, at Arles, France, van Gogh was faced with a specific problem in regard to painting at night. He was inspired by the contrasting colors, the quality of light, and the overhanging sky with its many glistening stars of a nearby outdoor cafe. Although the subject was well lit and easy to see, the canvas on which he wished to paint was not, and he had difficulty mixing paints and seeing his palette. He overcame the problem by experimenting with a wide-brimmed hat that had candles secured on it in various positions. What a sight he must have made to the residents of the small town of Arles! Surely, they thought him eccentric at best, and when in December of 1888 he had the first of several epileptic seizures and mutilated his ear, the candle-donning behavior could have added to their notion that he was insane and may have led to their subsequent efforts to encourage him to leave the town.

Among their reactions to him after the infamous ear-slicing incident were a petition circulated requesting that he leave and sporadic incidents of the local children taunting him at his window.

Van Gogh closed out the final 14 months of his life at two towns in France, St. Remy (in a mental institution being treated for seizures) and Auvers-sur-Oise. During periods of mental dysfunction, he did not create. In between attacks, he continued developing the ideas about creating he had previously set in motion. In this regard he wrote:

My work is going very well, I am finding the thing that I have sought in vain for years, and feeling this, I am always thinking of that saying of Delacroix's that you know, namely that he discovered painting when he no longer had any breath or teeth left.

At this point, his powers of rapid execution were refined so that he could quickly execute a rendition of a work by Delacroix in his own individualized style. He wrote, "[I]f you could see me working, my brain so clear and my fingers so sure that I have drawn that *Pieta* by Delacroix without taking a single measurement." The miner had been, and remained, a stabilizing metaphor for his working style, and he saw himself "like a miner who is always in danger makes haste in what he does."

Van Gogh continued to work purposefully, valiantly between epileptic attacks. In May of 1889, shortly after a psychotic episode, he wrote, "At present all goes well, the whole horrible attack has disappeared like a thunderstorm." He added his observation that his ability to render art firmly and quickly was improving: "I am working to give a last stroke of the brush here with calm and steady enthusiasm."

If there is any doubt that van Gogh was purposeful regarding his art can be dispelled, I would suggest by his description of his paintings of flowers, writing during May 1889:

I am doing a canvas of roses with a light green background and two canvases representing big bunches of violet irises, one lot against a pink background in which the effect is soft and harmonious because of the combination of greens, pinks, violets. On the other hand, the other violet bunch (ranging from carmine to pure Prussian blue) stands out against a startling citron background, with other yellow tones in the vase and the stand on which it rests, so it is an effect of tremendously disparate complementaries, which strengthen each other by their juxtaposition.

Van Gogh continued to paint right up until the end. "I have painted . . . vast fields of wheat under troubled skies," he wrote in the summer of 1890, "and I did not need to go out of my way to express sadness and extreme loneliness." "Well," he stated in his last letter, found unfinished on his person when he shot himself, "the truth is, we can only make our pictures speak." And speak they did and do to countless people of all nations and languages. Van Gogh never wavered from his intention to establish a new visual vocabulary for the expression of universal emotions.

During his adult years, van Gogh wrote copious letters. Most were to his brother Theo, who retained the great majority of them. Conversely, and unfortunately, Vincent did *not* retain the letters sent to him by Theo, so we have essentially a one-way correspondence. One of the reasons van Gogh's letters are powerful is that they are pure "thinking aloud" materials. He carried paper with him and jotted down his thoughts while he was creating. His writings are not distorted by the passage of time and the haziness of memory that attends it.

Van Gogh wrote many letters to his brother Theo, and to other friends and collaborators. The letters give a firm picture of van Gogh's thinking during critical phases of creativity. They also supply us with a profile of the shifting quality of his moods and of the quality of his emotions toward significant persons, places, and activities. Quotes from his letters were utilized in this work to demonstrate the rich world of emotional and cognitive states he experienced and to show that his ideas provided the basis to produce art. In his letters, van Gogh reveals the gentleness, love of humanity, and clarity of thought about his art that he maintained throughout his creative process—properties of his personality that are not so apparent in the sensationalistically magnified actions of his brief psychotic behavior.

Van Gogh Chronology

- 1853–1870: Childhood in Holland; firstborn of six children.
- 1870–1880: Various jobs, including art dealer, lay minister, schoolteacher, book seller.
- 1880: Makes decision to devote his life to becoming an artist.
- 1880–1883: Early development as an artist, devotes this period solely to drawing; lives at The Hague and learns from his teacher Anton Mauve.
- 1883–1886: Moves back with parents at Nuenen; culmination of Dutch period.
- 1886–1888: Goes to Paris; encounters the Impressionists and palette enlivens; lives rest of his life in France.
- 1888–1889: Lives at Arles in south of France; collaborates with Gauguin; first attack of mental disturbance (the infamous ear-slicing episode in December 1888).
- 1889–1890: Voluntarily stays at St. Remy, a mental hospital.
- 1890: Stays at Auvers; treated by Dr. Gachet; suicide.

Lev Semenovich Vygotsky 1896–1934

Psychologist

Author of *Cultural-Historical Theory of Human Development*

This article is reproduced from the previous edition, volume 2, pp. 691–699, © 1999, Elsevier Inc.

LEV SEMENOVICH VYGOTSKY has become famous in the scientific world as the creator of the cultural historical theory of psychology. Born at the end of last century into a Jewish family living in one of the provincial towns of the Russian empire, he is thought by many to be one of the major figures in 20th century psychology. Among L. Vygotsky's major works available in English are Thinking and Speech (published in 1934; published first in the United States in 1962 as Thought and Language), Tools and Symbols in Child Development (written in 1930, published first in English in 1978, and in Russia at the end of the 1980s), and The History of the Development of Higher Psychological Functions (published in the 1960s). He also wrote a series of articles dealing separately with the development of creativity in childhood and adolescence.

Lev Semenovich Vygotsky.

Background

Lev Semenovich Vygotsky was born in the town of Orsha, Vytebskaya oblast' (former Mogilev guberniya) in Byelorussia on November 5, 1896 (old calendar style). In 1897 his family moved to the city of Gomel, where Lev Vygotsky spent his childhood and his school years. Orsha and Gomel were towns inside of the Pale, a few provinces where Jews were allowed to stay permanently in the Russian Empire. Lev returned to Gomel after finishing his university education in Moscow in 1917 and stayed there until January 1924.

Vygotsky's early interest in humanities and art was influenced by his family, one of the best educated in town. His father, Semen L'vovich Vygotsky (1869–1931), had graduated

from the Commerce Institute in Kharkiv and worked as a banker. A very respected man in the Gomel community, he devoted a lot of time organizing activities in different service organizations, including an educational association that created one of the best public libraries in the city. Family history, recorded by Lev Vygotsky's daughter, Gita Vygodskaya, stresses that the personality of Lev's father was not easy to deal with—he was often stern, but this did not prevent him from being a loving father.

The heart and soul of the family was Cecilia, Lev's mother. At home she upheld an atmosphere of love and care. She was well educated and, like her husband, fluent in several languages. By training, she was a teacher, but she never got a chance to work in school; her whole life was dedicated to raising her eight children and running the household. Lev was the second child in the family.

Lev received his elementary education at home, studying independently and having a tutor for consultation. He passed an exam for the first 5 years of elementary school and entered into a private all-boys secondary school. Lev was a very good student in all subjects, and teachers often commented on his gifted abilities. His favorite subjects were literature and philosophy, both objects of his youthful fascination and involvement. In 1913 Lev graduated with a gold medal from the gymnasium, a secondary school in prerevolutionary Russia that prepared students for the university.

With his honored diploma he could have been accepted by any university to study philology, his favorite subject, but for a Jew in prerevolutionary Russia such a course of study would not have been very practical: philology graduates became, in most cases, teachers in public schools, a position not available for Jews. Lev's parents advised him to become a doctor because this would allow him to live outside of the Pale.

Lev was admitted to medical school at Moscow University, but a month later he realized how distant medicine was from his true interests, and he transferred to the law school at the same university. This school opened the way for a career as a lawyer, which would have allowed him to live outside the boundaries of the Jewish settlements. But his deep interest in the problems of literature, art criticism, philosophy, and the philosophical analyses of art led him, in 1914, without interrupting his education at the law school, to enroll in the Historical-Philosophical Department of Shanyavsky's University. Soon after, however, he became interested in psychology, and he combined his training in law, literature, and history with psychology.

Vygotsky's first publications, written during his student years and recently discovered by his daughter, were devoted to the problems of literary criticism. His student graduation paper

“The Tragedy of Hamlet, Prince of Dutch, W. Shakespeare” had an unusual history. It was published 52 years after he wrote it and gained a reputation nationally and internationally as one of the most original and unique analyses of *Hamlet*. Few student graduation papers receive serious attention from the international academic community more than 50 years after they were written.

In 1917, after graduating from both universities, Lev Vygotsky returned to his family in Gomel. According to his daughter and biographer, Gita Vygotskaya, the seven years that Lev Vygotsky spent in Gomel before moving to Moscow were important in his professional and personal development. The time after the Great October Socialist Revolution (1917) and the civil war that followed were very difficult for Lev Semenovich’s family, which suffered diseases and the death of two of Vygotsky’s brothers. Nevertheless, during this time, Vygotsky was active in teaching in the pedagogical college, managing a theater, and publishing his own journal of literary criticism. Most important, he conducted scientific studies of the psychology of art and the psychology of education, which resulted in his first famous books *The Psychology of Art*, which was written in 1925 but first published in 1965, and *Pedagogical Psychology*, which was published in 1926 then “arrested” (withdrawn from libraries and destroyed) and forbidden for more than 60 years. This book was republished only at the end of the 1980s. After a very impressive presentation at the Second Psychoneurological Congress in Leningrad in 1924, Lev Vygotsky received an invitation to join the Moscow Institute of Psychology. He accepted the invitation. During the next 10 years of Lev Vygotsky’s career, he built a new psychology, a new approach to the study of human development, and a powerful school of thought.

He did all this as a Russian intellectual who was actively involved in building *Soviet psychology*, an effort to revise and reform psychology along Marxist lines and to build a new, objective materialistic psychology. The new Soviet psychology was challenged to address the practical needs of a new regime to form new educational, clinical, and academic systems.

Vygotsky together with his closest friends and colleagues, Alexander Romanovich Luria and Aleksei Nikolaevich Leont’ev, started this enterprise at the time when nobody knew how to build a “new psychology.” Vygotsky began by analyzing what he believed to be a “crisis of contemporary psychology.” He was very ill and in hospital at the time he wrote a book *The Historical Meaning of the Crisis in Psychology* (this book was finished in 1927 but was not published until 1982). At that time, psychology was divided into different scientific schools. While analyzing the theoretical differences of these schools, Vygotsky concluded that, in reality, two camps existed in psychology. One camp was *objective* psychology, built on the principles of natural sciences. I. M. Sechenov and Ivan Pavlov, and their studies of reflexes, were among the most famous representatives of this camp. The second camp was phenomenological, idealistic, *subjective* psychology. Vygotsky’s attempts to unite the contradictory objective and subjective fields resulted in the creation of the cultural historical theory of human development. From 1924 to 1934 Vygotsky had more than 270 published articles, monographs, and books.

Ironically and tragically, the rise of Stalin’s political regime resulted in closer, potentially dangerous scrutiny of Lev

Vygotsky and his colleagues as they worked enthusiastically to build a new Marxist psychology. They tried to save their activities by moving from Moscow to Kharkiv (Ukraine), where their situation was not so politicized. Vygotsky spent much of his last 7 years in trains traveling from Moscow to Kharkiv to Leningrad. During this time he worked intensively, knowing that he was terminally ill with tuberculosis. Vygotsky died prematurely in 1934 at the age of 37. His death spared him from the suffering inflicted on other leading intellectuals by the Stalin regime. His likely fate, if he had lived longer, is indicated by the treatment of his research. His work was banned in the Soviet Union and was preserved only as oral history by his family, colleagues, and friends until it was rehabilitated in 1956.

Despite Stalin’s effort to obliterate his research and ideas, and his short, difficult life, Vygotsky is now viewed by many as one of the most influential figures of 20th century psychology and pedagogy. Remarkably, the books and articles he wrote more than 65 years ago continue to inspire and excite new researchers and research, and to influence practitioners.

Vygotsky Psychology

The efforts of Vygotsky and his colleagues to build a new Soviet psychology led them into diverse areas of investigation. All of these areas were linked to the same core ideas of his theory and were drawn from and tested with empirical studies, many performed with innovative techniques. Because Vygotsky’s work on creativity flows from and is closely related to his cultural historical theory of psychology, it is important to introduce key elements of that theory before discussing how they relate to creativity.

According to Luria, Vygotsky liked to call his approach “instrumental,” “cultural” and “historical” psychology. Each term reflected a different feature of a new approach to psychology that Vygotsky proposed to explain the development of higher psychological functions. The term *instrumental* reflected the fundamental idea of the mediated nature of higher psychological functions. Unlike basic reflexes, which could be analyzed as a simple stimuli-response situation, complex psychological functions incorporate in their structure new elements— internal and external tools—that transform the whole structure of mental functioning. The analysis of tools, which individuals actively use as instruments to modify and master their own behaviors, became a necessary part of Vygotsky’s new approach.

The term *cultural* emphasized that aspect of Vygotsky theory that views cultural development as a unique direction in the development of the child, reflecting socially constructed ways in which society organizes the various types of tasks faced by a growing child and the physical and mental tools that society provides to the young child to master those tasks. The *historical* aspect of Vygotsky’s theory is closely connected to the *cultural* aspect. The set of tools provided by a given culture were invented and developed during the long course of human history. Thus, tools like language, arithmetic or algebraic systems, maps, and signs have a long history of development and accumulation of their social influence before they become available as special instruments for a child’s individual development. Because the invention and

development of cultural tools continues, *historical* also means not only something from the past, but also contemporary aspects of life that are in process of change, linking the past and the future.

The historical method of psychological analysis differs greatly from the traditional methods used in the West. Vygotsky wrote that the concept of historically based psychology is misunderstood by most researchers. For them to study something historically means, by definition, to study some past event, and hence they naively imagine an insurmountable barrier between historic study and the study of the present-day behavioral forms. In Vygotsky’s view, to study something historically means to study it in the process of change. That is why he argued that the historical study of behavior is not an auxiliary aspect of theoretical study, but rather forms its very base. In fact, studying something in the process of change is the basic demand of the dialectic method, which is an essential element of Vygotsky’s theory.

The *dialectical method*, incorporated by Vygotsky in his work owes much to Hegel’s dialectic concept, which was later used by Marx and Engels. The Hegelian dialectic concept views things as in constant change and movement. It is concerned with interrelations and interactions. The sources for constant movement and development, the driving force of change, are conflicts and tensions between the contradictory aspects of things. As a result of these conflicts and tensions, development was viewed as constant transformation: nothing can be stable, everything is in a constant process of becoming.

Vygotsky viewed the very essence of psychic development as lying in the change of the *interfunctional structure of consciousness*. He criticized the atomistic and functional models of analysis, which treat psychological processes in isolation while ignoring their interdependence and their organization in the structure of consciousness as a whole. Rejecting methods of research perfected to study separate functions, Vygotsky suggested that psychology’s main problem for investigation should be the changing relationships between psychological functions and their developmental changes. The basic characteristics of Vygotsky’s theory are summarized in Table I. As this framework shows, Vygotsky separated higher psychological functions (like creativity) from natural psychological functions, then compared them based on their origins, structure, functioning, and complexity.

As Table I shows, natural psychological functions are genetically inherited (their origin), they are unmediated (their structure), they are involuntary (their way of functioning), and they are isolated from each other (their relation to other mental functions). In contrast, higher mental functions are socially acquired, “instrumental,” mediated by social means, voluntarily coconstructed and controlled, and exist as a part of a broad system of functions rather than as separate elements (see Table I).

Vygotsky On Creativity

The starting point for understanding Vygotsky’s view of creativity is that he believed that creativity is a higher psychological function. It is one of the complex and multidimensional human characteristics that distinguishes us from animals. Creative imagination is linked to the free processing of elements of our experience, creating their free combinations. It requires an inner freedom of thinking, activity, and cognition that is possible only for “cultural man.” Vygotsky stresses that it is freedom of creativity that distinguishes us from animals even more than intellect does.

He characterized creativity as the ability of humans to deal not just with the past or react to the present, but the ability to deal with change and with the future. Such an ability is lacking in animals, children of early age, and primitive humans. They all are unable to act creatively, to reach beyond the concrete situation and free themselves from a total dependency on the present. Vygotsky viewed imagination and creativity as equal parts of all aspects of cultural life, including artistic, scientific, and technical creativity. In this sense, all that is the work of the human hand, the whole world of culture, was distinguished in his view from the natural world because it is a product of human imagination and creativity based on imagination.

To explore Vygotsky’s views on creativity, the framework in Table I is used to structure the remainder of this section. We discuss these key points: (a) creativity has social origins and is culturally and historically determined; (b) creativity has a mediated structure; and (c) creativity exists not as a separate function but as a part of a more complex system, and changes during developmental stages.

Social Origins of Creativity

Vygotsky believed that the origins of individual creativity can be found only in the individual’s social relationships with the world. Creativity, like all other higher psychological functions, begins in the social environment and then through the process of *internalization* moves from the “outside” into the “inside.” His view was the opposite to the Piaget’s, who believed that intelligence is started and matured from inside the individual and then is directed from the inside to the outside. Internalization, according to Vygotsky, is a dialectical process that occurs during a child’s interaction with others: children watch other people speak, think, or behave in certain ways and thus can learn how to speak, think, or behave this way themselves. A child can learn how to think creatively only by first trying to do it together with other people. After that, the child can then internalize and model what has been done socially at first.

Once the process is internalized, it becomes a property of the inner psyche, even though Vygotsky never drew a real line between the inner and outside because the dialectic nature of internalization is a mechanism of human development. Vygotsky described this basic idea in his theory, which he called the *general law of cultural development*, as follows: Each higher psychological function in child development appears on the stage twice. It is seen first as a social collective activity, an interpsychological function. At the first stage of

TABLE I
Main Criteria of Differences between Natural and Higher Psychological Functions

Psychological functions	Origin	Structure	Functioning	Complexity, integration
Natural psychological functions	Mainly inherited	Unmediated direct	Involuntary	Relatively isolated
Higher psychological functions	Social origins, culturally acquired	“Instrumental,” mediated by cultural tools (verbal and external), which transforms the structure of mental functioning	Activity, voluntarily co-constructed and controlled	Systemic, always arise as part of complex integrated functional systems

development, adults are viewed as external agents mediating the contacts that children have with the world.

Second it is seen as an individual activity, which is the inner manner of a child's thinking, an intrapsychological function. At the second stage, the tasks that the child initially shared with an adult could be performed alone, they are internalized. As a higher psychological function, creativity follows this pattern in development. Because Vygotsky believed that a child can acquire abilities for creative thinking through the interaction with adults, there was no doubt for him that creativity, creative thinking, could be enhanced through appropriate teaching. Vygotsky believed that good teaching can lead to the development of a child's creativity if it is based on the principles of the *zone of proximal development*.

The concept of the zone of proximal development is a very influential Vygotskian idea. It is defined as the distance between (a) the actual development level of a child, as determined by independent problem solving and (b) the level of the child's potential development, as determined by problem solving carried out under adult guidance or in collaboration with more capable peers.

Creativity has Mediated Structure

As noted earlier, Vygotsky described the cultural development of higher psychological functions as a dialectical process that goes beyond incrementally improving the elementary functions to stimulate fundamental changes in the direction of development. Thus higher psychological functions like creativity are not built *on* (on the top of) the elementary functions, but are separate, new psychological systems. This radical transformation of the structure and the functioning of higher psychological processes is based on the use of signs, words, symbols, and other cultural tools, which become psychological tools for organizing behavior. The structure of higher psychological processes become mediated and, in some cases, could be flexible, depending on the nature of tools that are used.

According to Vygotsky, creativity as a mediated activity means that creativity as a higher psychological process could have a very different structure, depending on what cultural tools are available at a given moment and which kind of cultural tools a person uses for its mediation. The direction of creativity depends on the tools that are supplied to a given individual, which is determined by the culture and history of the society in which the person lives. Vygotsky argued that it would be a miracle if the imagination could create something from nothing, or if it had another source of creation besides previous experience. He stressed that the creative activity of imagination is found to depend primarily on rich and varied previous experiences. The richer the person's experience, the more material his imagination has at its disposal. Accordingly a child has less imagination than the adult because he or she has less rich and diverse experiences.

Vygotsky wrote that any inventor, even a genius, is always a plant growing at a certain time and in a certain environment. His creativity issues from needs, which are given to him. He operates with the possibilities that exist around him. Because of this, we can trace the historical development of technical areas and the sciences. He stresses that no inventions of

scientific discoveries can occur before the materials and psychological conditions necessary for their creation are at hand.

So, Vygotsky viewed creativity as a mediated activity and he attempted the scientific analysis of different types of mediation. He specifically studied symbolic mediation, which is originated during the interaction in child play as a visual, perceptual mediation and then transformed during adolescence into the verbal, symbolic mediation.

The Development of Creativity

Rejecting the model of development as the linear, gradual accumulation of small changes, Vygotsky described development as a dialectical transformation that includes both evolutionary and revolutionary changes. He applied this approach to analyze creativity and noted that even though creativity usually appears to be a "catastrophic act," it is actually the result of a very lengthy internal maturation. For Vygotsky, evolutionary changes (maturation) and revolutionary shifts (catastrophic act) in creative behavior were not opposite forms, as could be viewed from the "commonsense" point of view. Instead, he viewed them as mutually dependent forms of the dialectical process of the development of creativity.

Vygotsky argued that creativity, as one of the higher psychological functions, cannot be studied separately without taking into account its relationships with other psychological functions in different stages of the development of the individual. For Vygotsky, the dialectic of the relationships among memory, perception, abstract thinking, and motivation play a major role in the systematic analysis of creativity and imagination and its development.

Vygotsky wrote that creativity as a higher psychological function does not appear suddenly; instead it develops slowly and gradually from more elementary and simple forms to more complex forms at each age level of childhood, which has its own form of creativity. It does not appear by itself in the behavior of the child as a separate psychological function, but it emerges in direct dependence on other forms of activity and other psychological functions.

Vygotsky found that creativity in childhood differs from the creative abilities of adults. The imagination of children is poorer than the imagination of adults. In the process of child development, the imagination also develops, reaching maturity when the child become an adult. He describes child play as the first activity during which creative imagination appears, mediated mainly by perception, memory, and visual thinking. During the same period, a child first becomes aware of differences between reality and imagination and develops the ability to undertake symbolic play. [See PLAY.]

In the adolescent stage of development, creativity begins a revolutionary shift that is caused by the appearance of new powerful mediators, inner speech and abstract thinking. At this stage of development, creativity changes due to complex interfunctional connections between imagination and abstract thinking. In Vygotsky words, creativity "is intellectualized." It enters into a system of intellectual activity and begins to play a completely new function in the structure of adolescent personality. From the developmental point of view, argues Vygotsky, imagination in the adolescent is the successor of children's play.

Vygotsky argued that imagination of the adolescent is more creative than a child's fantasy, but it is not productive in comparison with the fantasy of an adult. Only in adulthood does creative imagination and creative thinking reach maturity in the form of artistic, scientific, and technological creativity. [See IMAGINATION.]

Conclusion

Drawing on his cultural-historical theory of psychology, Vygotsky attempted to analyze creativity from inside of culture and history. He regarded individual creativity as a higher, mediated psychological process, whose origins could be found only in the individual's social relationships with the world. Vygotsky view of creativity is optimistic: He sees that humans have the ability to develop creativity and to formulate the fundamental laws of its development.

Glossary

Aggregate units Units of analysis that tabulate cases across time or space. Examples include counting creative geniuses in consecutive generations or the number of Nobel laureates in different nations.

Content analysis A systematic method of extracting useful information from documents, artifacts, or products.

Generational time-series analysis A statistical method in which a transhistorical sample of eminent personalities are assigned to consecutive 20-year periods and then subjected to various statistical analyses.

Integrative complexity A measure of the extent to which an individual can differentiate alternative perspectives and then integrate those perspectives into a coherent viewpoint.

International war Enduring and organized military conflict between two or more sovereign or independent states. Sometimes referred to as balance-of-power wars.

Intranational war Enduring and organized military conflict within a single sovereign or independent state. Can include civil wars, rebellions, and revolts.

Power motivation The need to influence on or exert dominance over other individuals, whether aggressive, sexual, or social; the desire for prestige and respect.

Time-lagged relations Associations between two variables that occur after some time delay, the length of the lag being dependent on the time needed for the causal variable to have an impact on the effect variable.

Time-series analysis A series of measurements on the same case spread over consecutive periods of time; most often the assessments are equally spaced.

Introduction

Is personal and societal creativity positively associated with peace and prosperity? How does warfare affect the creative output of a given individual or nation? Does war determine both quantity and quality of cultural and intellectual activity?

A superficial glance at history might lead us to suspect that war features positive relation with creativity. At the individual level we might cite the example of Ludwig van Beethoven: many of his masterworks seem to have appeared during the height of the Napoleonic Wars. Indeed, he had originally planned to dedicate his Third 'Eroica' Symphony to Napoleon himself. At the societal level we might mention the Golden Age of Greece, a period of high cultural achievement framed by the Persian and Peloponnesian Wars. The Italian Renaissance provides another apparent example. Did not Leonardo da Vinci devote part of his creativity to designing weapons? And did not Michelangelo help design fortifications? Of course, it is also possible to come up with counterexamples. On the one hand, the famed Pax Romana – a period of relative peace during the Roman Empire – also was associated with a great cultural florescence, such as the so-called 'Silver Age' of Latin literature. On the other hand, it would seem that World War II had a devastating impact on creativity in Europe and Asia.

Rather than continue to pit one anecdote against another, it is possible to address this question in a more objective and

quantitative manner. In particular, the optimal approach is to apply historiometric methods to biographical and historical data. Fortunately, a large number of diverse studies have been conducted on this issue. The vast majority of these investigations focus on how war might influence creativity, so that research will be discussed first. But a smaller number have looked at how creativity might be involved in war, a possibility examined toward the end.

Effects of War on Creativity

In general, war can affect creativity in two ways: quantitative and qualitative. The first concerns the actual output, such as the number of creative products produced in a given year. Does warfare help or hinder the odds that creativity will appear? The second concerns the nature of the output, such as its thematic content or stylistic characteristics. Does peacetime creativity look different than wartime creativity?

Quantitative Effects

How does war affect creativity? It turns out that this question is much more complex than first meets the eye. Research cannot begin to provide an answer until the investigator first responds to three subsidiary questions.

First, what exactly is meant by war? At the very least two different kinds of war can be distinguished. On the one hand are the wars between sovereign states, such as World War I among several European nations. This type of conflict is sometimes referred to as an international war. On the other hand are the wars that take place within a given sovereign state, such as the English Civil War of the mid-seventeenth century. This type of conflict is sometimes called an intranational war. However, these two labels do not exhaust all of the possibilities. For instance, another kind of war is the imperialistic or colonial war where one modern nation-state subjugates foreign peoples, especially those who have a tribal rather than national political structure. Needless to say, different varieties of war need not have the same impact on creativity. Complicating the situation all the more is the issue of how to assess the state of war. Is it merely a matter of counting the number of nations that have declared war? Or should the number of pitched battles or war casualties be taken into consideration? What about the war's economic costs?

Second, what exactly is meant by creativity? It has become customary to distinguish between two levels of creativity, 'little-c' or everyday creativity and 'Big-C' or genius-level creativity. War might not exert the same influence on both. In addition, it is obvious that creativity appears in many different disciplines. At the very minimum, scientific creativity must be separated from artistic creativity. Yet it may be necessary to make finer distinctions as well. Certainly more expensive art forms like architecture might suffer more from military conflict than less expensive forms like poetry. In the case of the sciences, applied disciplines like medicine and technology may receive a boost at the expense of pure disciplines like botany and mathematics.

Third and last, what is the unit of analysis? This turns out to be a very complex issue. To begin with, the investigator must decide whether the units are going to be individual or aggregate. Individual units concentrate on samples of creators or their creative products. Such units are designed for asking whether people are less creative if they grow up in wartime conditions. In contrast, aggregate units concern samples of individuals organized into larger entities, such as nations or civilizations. Such units are best for addressing whether societies that more often engage in war are more likely to have fewer creative geniuses. Another issue is whether the units are to be cross-sectional or longitudinal. Cross-sectional units could entail samples of individual creators or independent nation states. Longitudinal units, in contrast, would examine one or more units across time, where those units may be either individual or aggregate. For example, a researcher might examine how war affects the annual output of creators or nations. Most often the units are arranged into time series and thus subjected to some kind of time-series analysis. Whenever time series are used, the investigator must decide on the size of the longitudinal unit. The most common choices are years, decades, or generations, where the latter is taken as somewhere between 20 and 25 years in length. Shorter time-series units are optimal for studying the momentary effects of war whereas longer units are optimal for studying the more enduring consequences of war.

The answer to these three questions largely determines the empirical results. Indeed, the one secure conclusion that can be drawn from the literature is that the relation between war and creativity depends on the definitions of war, creativity, and the

units of analysis. To appreciate this dependence, below I report the key findings under two headings, aggregate units and individual units.

Aggregate units

Some researchers have counted the number of creative geniuses appearing in consecutive generations in the history of an entire civilization, where the creativity could come from any major domain in the arts and sciences. The fluctuations in these counts were then compared with the occurrence of international wars (sometimes weighted by the number of casualties). The same findings have appeared for both Western and Eastern civilizations: military conflicts among independent states have no relation, positive or negative, with societal creativity. This null result explains why it is so easy to find examples of creativity under wartime conditions and creativity under peacetime conditions. Both possibilities occur with roughly equal likelihood.

Even so, by various changes in the methodological design, it becomes possible to observe some variety of war-creativity connection. For example, one investigation scrutinized the relation in Western civilization since the Renaissance, but introduced the following changes: (a) the unit of analysis was the year rather than the generation; (b) creativity was restricted to science and technology; (c) the creativity measure entailed an annual count of discoveries and inventions rather than individual scientists and inventors; and (d) war was split into four different categories, namely balance-of-power (or international) wars, civil (or intranational) wars, imperial (or colonial) wars, and defensive wars (when Western civilization was under attack by a non-Western civilization, such as the Ottoman Empire). In this case, negative effects were observed for balance-of-power and defensive wars. Over all, the following balance-of-power wars had the most destructive effect on discovery and invention in modern Western civilization: the Thirty Years' War, the Napoleonic Wars, and the two World Wars. Other inquiries have replicated this finding, particularly in the case of World Wars I and II. The latter even had an adverse effect on creative contributions in psychology.

The preceding studies concentrated on the concurrent or contemporaneous relation between societal creativity and war. The amount of war in a given year was directly compared with the number of discoveries and inventions in the same year. Yet it is also possible that the causal relation between the two variables is time lagged. That is, the impact is not immediate but rather manifests itself after a decade or more. This possibility has been tested using generational time-series analysis. In this technique historic creators and political events are tabulated into consecutive 20-periods called generations. The number of creators in generation g can then be correlated with the event counts in generation $g - 1$, or 20 years earlier. Because creators are assigned to the time-series units according to their peak productive period (most often taken as age 40), creators in generation g would be in their developmental phase in generation $g - 1$. Hence, this time-lagged function can assess whether certain political events, including war, exerts an effect on creative development.

Although the allowance for time-lagged generational does not alter the picture for international war, the provision does change conclusions for various kinds of intranational war.

Most prominently, revolts and rebellions directed against the hegemony of imperial states tend to increase the level of creative activity in a civilization. It seems that large empires tend to enforce a degree of cultural homogeneity that is antithetical to creative development. Interestingly, another kind of internal violence, namely, political instability, can have the opposite effect after a generation delay: 20 years after military revolts, coups d'état, and political assassinations a civilization tends to witness a decline in the number of creative geniuses.

One peculiarity deserves special mention: the impact of the diverse varieties of warfare depends on the domain of creativity under scrutiny. Most notably, creativity in the arts tends to be less affected than creativity in the sciences. Scientific creativity may require more ideal conditions than artistic creativity.

Individual units

The empirical findings reported in the previous section all depended on data aggregated across large numbers of creative individuals. Indeed, many of the investigations tabulated thousands of geniuses into 20-year generational time series. It is conceivable that such aggregation obscures the relation between war and creativity. Especially in a large civilization area, some creators will be more directly affected by war than others. While World War I was quite injurious to creativity in Europe, its consequences for creativity in the Americas was minimal. Thus, it might be better to investigate how war affects creativity at the individual rather than aggregate level.

Unfortunately, far fewer researchers have taken this alternative approach. One study examined creative output in ten top classical composers and still found that international war had no influence one way or another. Another study, using a very similar design, showed that the creative output of ten top psychologists declined during times of international war. Both of these investigations counted output in five year periods across each creator's career. Potentially even this degree of aggregation may mask the more transient effects of war. An alternative is to use an even finer unit of analysis, namely individual creative products. For instance, a study of 1935 compositions in the classical repertoire found that the most frequently performed works are less likely to be created during times of international war. So this particular form of artistic creativity may be encouraged by peacetime conditions.

Qualitative Effects

Even though certain types of war appear to have quantitative effects on specific kinds of creative activity, these effects are weak. Seldom is a military conflict so extensive that it shuts down creativity altogether. Because some creators will reside sufficiently far from the war zone, creative products will still appear, even if at a reduced rate. Consequently, it becomes possible to ask whether the works that appear in times of war differ from those that emerge in times of peace.

Various historiometric studies have addressed this question using an even more diverse set of methodological approaches. Probably the most important difference is the domain of creativity that is under investigation. Clearly, the thematic and stylistic parameters of creative products are contingent on the domain of creativity. For instance, a musical composition cannot be assessed by the same criteria as a scientific journal

article. Accordingly, it is optimal to organize this section according to creative domain. More specifically, the discussion here will separately cover music, literature, and philosophy, and science. The visual arts appear to be missing from this survey, but there appear to be no published studies of how war might affect the style or content of paintings, sculpture, and architecture. Perhaps this omission reflects the difficulty of analyzing the visual arts for this purpose.

Music

One approach to assessing the qualitative effects of war is to apply content analysis to creative products that are generated under either wartime or peacetime conditions. The content analysis may take two major forms: subjective and objective. Subjective content analysis requires trained human judges to apply well-defined coding schemes to a given document or artifact. In contrast, objective content analysis requires that a computer program apply the coding schemes without the intervention of a human being. Both of these approaches have been applied to compositions that make up the classical repertoire. The empirical research using these methods has shown that music is often responsive to the stresses and strains occurring in a composer's personal life. And it is hard to imagine war having any less of an effect. In point of fact, investigations have indicated that concurrent warfare has a major impact on the stylistic content of compositions. For example, compositions penned during wartime exhibit much greater variation in melodic originality; extremely predictable and extremely unpredictable themes being found in the same work. It is almost as if highly stressful contemporary events polarize the creator's emotional reactions, inspiring vast mood swings between resignation and despair, hope and fear. Furthermore, the stylistic impact of war appears to intensify to the extent that the composer resides close to the actual war zone. Shostakovitch's Leningrad Symphony, written during World War II, may provide a graphic auditory example of the magnitude of this polarization of trite and profound in melodic material.

Given that classical music constitutes a relatively abstract form of artistic creativity – where style seems more crucial than content – it might seem surprising that compositions are so responsive to external conditions like war. In the next domain of artistic creativity such a connection would be more likely expected.

Literature

Ben Jonson said that William Shakespeare "was not of an age, but for all time." Nevertheless, it is evident from the empirical literature that he definitely wrote his plays for his own age and time. The thematic material often reflected current events, particularly the most dramatic of these events. And it is difficult to imagine an event more striking than military conflict. So, in line with expectation, Shakespeare's thematic content tended to be responsive to wartime circumstances. In the first place, whenever his native land, England, was attacked by a foreign power, his plays had a tendency to discuss political expansion, empire, and conquest as the goals of war. In addition, various revolts and rebellions would stimulate discussion of life's conflicts. Even conspiracies against the monarch left an imprint on the Bard's plays. Nor was Shakespeare unique in his responsiveness to international and intranational war. Comparable

results appear to hold for the ancient Athenian playwrights Aeschylus, Sophocles, Euripides, and Aristophanes.

Content analytical studies have found that international war affects the content of poetry as well. Poems written during wartime are noticeably different from those written in peacetime. For instance, one investigation scrutinized how concomitant war casualties related to the content of French and English poetry. When wartime deaths and injured intensified, poets were more likely to treat moral imperatives (more often using such words as should, right, and virtue in their poems) but were less likely to invoke the theme of chaos (less often using such words as wild, crowd, and ruin). Just as intriguing, war intensity was positively associated with content indicative of rationality, restraint, and control. All in all, wartime poems place more emphasis on maintaining the moral order in the face of evil and chaos.

Finally, it is worth mentioning a curious relation between war and a very specialized literary theme – that of Don Juan. Although Don Juan legend originated in Spain, he proved to be such a popular character that various versions appear in other national literatures as well. In any given literary tradition, the frequency of Don Juan versions correlates positively with how much that nation was engaged in warfare. What makes this association most interesting is that the Don Juan theme can be linked with the need for power. The character's sexual conquests are indicative of interpersonal dominance, just as war is an instrument of international dominance. Because war itself is also connected with power motivation, enhanced interest in the Don Juan reflects a national shift toward the need for power. Significantly, this literary theme peaks about a decade after the peak in warfare.

Philosophy

Philosophers are apparently no more immune from war's influence than are the composers and writers. This impact was demonstrated in an extensive generational time-series analysis of over two thousand thinkers from the ancient Greeks to modern Western civilization. A team of experts first rated the thinkers on the stances on several key intellectual issues. These issues included the fundamental nature of reality (ontology), the basis for human knowledge (epistemology), and the criteria for good and evil (ethics). These thinkers were then tabulated into separate generational time series for each philosophical position, yielding a measure of fluctuations in major intellectual ideas. Because war was hypothesized to function as a developmental influence, a time-lagged analysis was used. That is, the number of philosophers in generation g was related to the amount of war in generation $g - 1$, or 20 years earlier. Significant relations were found for both intranational and international war.

1. Intranational war, and especially substantial civil disturbances, has a polarizing impact on intellectual debate, again after a one generation delay. To be specific, 20 years after such collective violence philosophers tend to advocate (a) empiricism (all knowledge comes through the senses), rationalism (all knowledge comes through reason), and mysticism (all knowledge comes through revelation); (b) materialism (matter is the fundamental basis of reality) and idealism (spirit or mind is the fundamental basis);

(c) eternalism (reality is unchanging) and temporalism (reality is in constant flux); (d) realism (abstract ideas really exist) and nominalism (abstract ideas are but names in our language); (e) singularism (the individual is of primary importance) and universalism (the society is primary); (f) determinism (everything is caused) and indeterminism (humans have free will); and (g) the ethics of happiness (good and evil based on pleasure), the ethics of principles (good and evil decided by universal rules), and the ethnics of love (good and evil guided by compassion). It is as if the political polarization that causes intranational war in generation $g - 1$ induces ideological polarization in generation g .

2. In contrast, international war has a far more selective effect, and a negative one, discouraging the emergence of certain beliefs. In particular, one generation after major international warfare philosophers are less likely to advocate empiricism, temporalism, nominalism, singularism, and the ethics of happiness. In other words, thinkers are less prone to argue that knowledge comes through the senses, that reality is constantly changing, that abstract ideas are but names, that individuals have priority over society, and that moral decisions should be based on what causes pleasure and pain. Evidently, these particular stances are not favored during wartime conditions, perhaps because these beliefs might be antithetical to the extreme patriotism and self-sacrifice required for the war effort. So, future philosophers who grow up under such circumstances are less likely to espouse these beliefs as adults.

As will be shown later in this article, sometimes the causal relations can be reversed, certain ideologies increasing war after a generational delay.

Science

It was shown earlier that international war has an immediate impact on the annual output of discoveries and inventions. In the previous section, however, it was seen that war can exert a long-term influence on philosophical creativity. Given that scientific creativity is partially dependent on the prevailing philosophy of a given age, the latter result implies that war might have enduring consequences for science as well. For instance, it seems reasonable to infer that scientific ideas might become less empirical and materialistic in line with similar changes in philosophy. Regrettably, no research has investigated this possibility. Even so, one empirical study has indicated a possible immediate connection between war and science in psychology. Peter Suedfeld content analyzed the presidential addresses delivered by 85 Presidents of the American Psychological Association. The speeches were specifically scored for integrative complexity, a measure of how many distinct perspectives a person considers and the extent to which these perspectives are successfully integrated. Some of these presidential addresses were delivered during peacetime, whereas others were delivered during the Spanish-American War, one of the two World Wars, the Korean War, or the Vietnam War. Cognition was much more complex in those addresses given during times of peace. What makes this correlation even more interesting is that the distinguished psychologists who score high on integrative complexity tended to

practice a different kind of psychology than those who score low. The former are more prone to view psychology as a human science, and thus be more humanistic or clinical in their orientation, whereas the latter are more likely to see psychology as a natural science, and therefore be more behavioristic or experimental in orientation. By implication, the presence or absence of war seems associative with qualitative differences in psychological science.

Effects of Creativity on War

It has been assumed so far that creativity is somewhat at the mercy of politics. War either lowers the amount of creativity or else modifies the nature of the creativity that does appear. Despite that assumption, sometimes researchers have found evidence for influences going in the opposite direction. These consequences operate at two levels, the aggregate and the individual.

At the aggregate level, there is some tentative evidence that certain ideologies tend to encourage the development of the militaristic ideas that lead to war. This evidence came from a generational time-series analysis that compared the relation between prevailing philosophical beliefs at generation g and the level of international war at generation $g + 1$. When civilization becomes dominated by sceptical and materialistic ideologies, then warfare was likely to increase about 20 years later. This time-lagged relation held from the ancient Greeks to the beginning of the twentieth century. Because scepticism and materialism may undermine ethical values, and even lead to a high degree of political cynicism, the youth exposed to these ideas may be more disposed to become adults who are far more willing to see war as a viable means to attain a desired end. This possibility may bring to mind the ideal leader according to *The Prince* written in 1513 by Niccolò Machiavelli: the end justifies the means.

At the individual level, it becomes useful to return to the concept of integrative complexity. As noted earlier, integrative complexity tends to decline during wartime, and it tends to be associated with the type of psychology displayed by a President of the American Psychological Association. But the variable's connections with both war and creativity are even more complicated than so far discussed. To start with, integrative complexity is positively correlated with creative problem solving. Creative people are able to look at a problem from multiple perspectives and, when necessary, discover a solution that integrates those alternative points of view. Thus, Albert Einstein examined a problem in physics from the standpoint of both Newtonian mechanics and Maxwellian equations, saw the contradiction between the two, and resolved the conflict by deriving his special theory of relativity. By the same token, high integrative complexity is associated with effective leadership, especially in the area of decision making and problem solving. For instance, the more successful US presidents score higher in integrative complexity than do the less successful. In the case of war, integrative complexity is involved in two ways.

First, research has shown that international crises are more likely to result in international war when the political leaders facing crisis score low in integrative complexity. If the goal is to resolve the conflict, then leaders must be able to examine the

issues from multiple perspectives, and then find a satisfactory integration of those perspectives. The various parties to the crisis can then identify a resolution that allows the tensions to be reduced peacefully. If the leaders score low in integrative complexity, they can only see the crisis from one point of view (their own), and reconciliation becomes impossible. War then becomes the only answer. In a sense, when a crisis results in war, it is a sign that the world's leaders failed to exhibit sufficient creativity.

Second, once war breaks out, military leadership becomes more critical than political leadership. To a very large extent, the nations with the superior commanders will have an edge over their opponents in the conflict. Research indicates that those military leaders who score highest in integrative complexity are most likely to emerge victorious in battle. To be effective, a commander must be able to view the military situation not only from his point of view but also from that of the enemy commander. By inspecting the situation from all possible perspectives, the commander can determine the most probable consequence of a given tactical decision. In short, the leader can 'second guess' his opponent. Of course, integrative complexity is probably an asset with respect to strategy, and not just tactics. Hence, it enhances the national capacity to win the war, not just the battles making up the war. In short, military success demands a certain amount of creativity.

These two points taken together point to an ironic conclusion: It may take some amount of creativity to avoid war, and also a certain amount of creativity to win a war once it has begun.

Conclusion

Creativity is an enormously important phenomenon. Modern culture is largely the accumulation of creative acts since the beginning of civilization. War is also a tremendously significant phenomenon. Few political events affect so many people so dramatically, and often permanently. The history of humanity is very much a narrative of its major wars, battles, and conquests. Putting these two obvious facts together might lead to the conclusion that the relation between creativity and war would be a frequent subject of research. Yet that is far from the case. Direct empirical studies of their association are actually quite rare. To be sure, this article has reviewed a rich inventory of empirical results. However, close examination of the literature shows that the diverse findings are scattered and disconnected. Too often one investigator will approach the topic in ignorance of past research already published on the subject. As a consequence, frequently researchers end up duplicating results rather than building on the prior results of their predecessors.

Another liability has to do with the lack of a strong theoretical foundation for almost all published inquiries. The typical investigation tends to be exploratory, war constituting just one of numerous situational factors thrown into a set of independent variables. Complicating the problem all the more, investigators do not always define war in the same way, thereby obtaining divergent results. Furthermore, as mentioned earlier, researchers have often employed rather diverse methodological approaches, such as contrary units of analyses. Such contrasts can also affect the outcomes.

In light of these unfortunate limitations in the research, it is hoped that future investigators will adopt a more systematic approach to this crucial question. In particular, subsequent investigations should adopt a stronger theoretical framework that more firmly guides the critical methodological choices. Until then, those curious about the relation between creativity and war must be contented with a heterogeneous collection of piecemeal observations.

Introduction

Max Wertheimer was the creator of Gestalt psychology. The Gestalt 'school' arose in opposition to the four elementaristic, atomistic systems of psychology that were dominant early in the twentieth century, structuralism, functionalism, behaviorism, and psychoanalysis. Wertheimer demonstrated in analyses of music, creative thinking, perception, and many other areas of psychology that conceptualizing psychological processes and events in terms of the combination of 'elements' such as sensations, complexes, associations, or reflexes does violence to these processes and events; rather than psychological wholes being merely the sum total of their constituent elements, or the sum total plus some added element, wholes are entirely different from a sum of their elemental constituents. The nature of the whole determines the place, role, and function of each of the parts that make up the whole. The power of this kind of conception was concretely demonstrated in the many examples of dynamic thought published in his posthumous work, *Productive Thinking*. While the Gestalt movement waned somewhat during the second half of the twentieth century, its validity and applicability in a wide range of areas was once again recognized late in the century and early in the twenty-first in domains as diverse as cognitive science, visual neuroscience, art, social psychology, and the psychology of personality.

Max Wertheimer

Max Wertheimer.

Background

Wertheimer was born 15, April 1880, into a prominent family in the Jewish community in Prague, then a major city in western Austria-Hungary, and later the capital of Czechoslovakia.

His father Wilhelm, the son of a prosperous businessman, pursued a career in accounting, agricultural commodities, and banking, and founded and directed a successful business school in Prague; his mother Rosa had a rich classical education in music, politics, and the arts. In keeping with the social stratification at the time, the language used at home was German; Czech was used only on the street and with shopkeepers.

Max's older brother Walter became a teacher in Wilhelm's business school, but died when he was in his late twenties. While Max was raised in the Jewish tradition, he did not carry on these practices into his adulthood. His parents sent him to a Catholic Gymnasium (or secondary school), because of the high quality of its reputation as assuring an excellent broad scholarly background for students aspiring to a university education. But doubtless the holistic perspective of the Jewish tradition at home played a role in Wertheimer's intellectual development. Holism has been a part of western philosophy for millennia; it can be traced back to classical Greek antiquity. And a resurgence of holism was a major trend among the late nineteenth-century Central European intelligentsia; a favorite topic of discussion, for example, was the skill of a good symphony orchestra conductor: the result of an accomplished conductor's skill is an experience for the listener of a profound, unified work that transcends just the concatenated sum total of the sounds made by the individual musicians.

Wertheimer's early independence of thought, as evidenced in his brother Walter's diary, was already clear when, as an adolescent, Max defied his parents at the dinner table by asserting that memorizing various items in the Bible has nothing to do with truly understanding religion or the Bible; this distinction between sheer blind memorization and true understanding or insight was to become a prominent feature in his later adult analyses of productive thinking and of education.

Early Adulthood

Wertheimer entered Charles University in Prague in 1898 and, following his father's wish, began to study law. But his exposure to philosophy and psychology, as well as to the humanities – and especially his repugnance toward the idea that a lawyer's duty is to the welfare of the client rather than to the establishment of truth and justice – persuaded him to pursue graduate work in philosophy and psychology instead. After five semesters studying law and then three concentrating on philosophy and psychology at Charles University, he transferred for graduate studies to the University of Berlin, at the time the most prestigious university in the German-speaking world.

Wertheimer was profoundly stimulated not only by the superb university, but also by the artistic, architectural, musical, political and intellectual ferment in Berlin at that time. He became close friends with the family of the highly successful graphic artist Käthe Kollwitz, and indeed lived with her sister's

family for several years. His dissatisfaction with what he considered the dull, pedantic elementaristic perspectives that dominated the psychology of the time led him to consider switching to the University of Würzburg, where the predominant views concerning psychology had a distinctly holistic cast. In Berlin, he performed experiments with a fellow student in 1902 that concerned the determination of guilt (in a legal sense), and these experiments were very similar to work already going on at the time in Würzburg.

Thus in the summer of 1904, probably with the blessings of his mentors in Berlin who themselves had distinct leanings toward holism, Wertheimer enrolled at the University of Würzburg. When he went there, graduate students were working on such issues as the qualitative characteristics of mental associations, the 'imageless' nature of many thought processes, the 'directedness' of thinking, and how the laws of logic are not really identical to the laws of actual thought. Würzburg was a major world center for creative experimental work on the psychology of thinking. By the close of that same year, 1904, Wertheimer successfully defended his doctoral dissertation on lie detection, a direct outgrowth of the work he had begun in Berlin on the determination of legal guilt. His Ph.D. was conferred on him with highest honors (*summa cum laude*).

Wertheimer's strategy in the lie-detection experiments was ingenious. He would tell a vivid story about a crime to some subjects in the experiments, but control subjects would be told a different story. Then a word-association test was administered to both sets of subjects. Some of the words would refer to items that only the experimental subjects would know had something to do with the crime, and indeed it turned out to be possible without exception to determine from the subjects' responses – their reaction time, their flustering, their emotional demeanor – which ones had been exposed to the crime story. If, for example, the story concerned the theft of a valuable gold chalice with the monogram FH embossed on it, that had been kept on a shelf in a special oak glass-enclosed bookcase, the critical subjects, but not the control subjects, would react in a telltale way to such word-association stimuli as 'FH,' 'gold chalice,' or 'oak bookcase.' Wertheimer's reasoning was that actual perpetrators of a crime would know about various details of the crime that innocent suspects had no way of knowing, and that their emotional reaction to these details would unerringly give them away. An emotional response to such ambiguous questions as "did you steal x?" could be expected from innocent suspects as readily as from guilty ones, but a discriminative response to critical features of a crime that could be known only to the actual perpetrator is an infallible indicator of true guilt. This technique of lie detection (finding that suspects who deny they committed the crime are in fact guilty) was to become one of the (few) methods of lie detection that would be acceptable in courts of law.

Beginnings of Gestalt Theory

Wertheimer stayed mostly in Berlin during the next few years, enjoying the stimulating intellectual and artistic opportunities in that exciting city. He performed and published further studies related to the lie-detection theme of his doctoral dissertation. He also worked on aphasia (a kind of word-blindness)

and brain injury, other neurological and physiological projects, and the psychology of music at research centers in Prague, Frankfurt, and Würzburg as well as Berlin. His work with brain-injured patients, trying to determine experimentally the exact nature of the patients' cognitive psychopathology, and his forays into sociocultural aspects of music – and also a preoccupation with philosophical issues of epistemology and logic, soon resulted in the coalescence of a holistic perspective that eventually culminated in the formal recognition that natural wholes not only in psychology but also throughout the physical world as well are not merely the sum total of their constituent associated elements, not even the sum total of such parts plus some added emergent element, but fundamentally different from a mere sum of such isolated components. Indeed the whole is prior to its parts, not a product of their combination. And the nature of the whole determines the nature of its parts, rather than vice versa. The precise formulation of this perspective was still several years away, but its beginnings are already clearly discernible in several papers Wertheimer published early in the second decade of the twentieth century.

The first one was a 1910 paper on the music of the Vedda, a tribe in Ceylon (now Sri Lanka) that was considered among the most primitive cultures then still extant. Wertheimer had spent some time during his years at the University of Berlin at a major phonogram archive there of music recorded in many parts of the world, including the songs of the Vedda. In contrast with an earlier analysis of this music, claiming that it is irregular, primitive, and 'undeveloped,' at least in comparison with modern European music, Wertheimer's analysis was much less ethnocentric. He clearly admired the songs, even if they were composed of only two or three different tones, as displaying a sophisticated internal structure, with specific 'laws' that govern their rhythm and internal articulation. His comments on this admittedly primitive music can be seen as perhaps the first specifically Gestalt analysis of a specific phenomenon; his approach, like in many later publications on Gestalt psychology, sought to discover how characteristics of a whole (in this case an entire melody) determine the nature of its individual parts (in this case the notes and their rhythmic and pitch characteristics and relationships).

A second early paper, in 1912, also on an ethnopsychological theme, concerned the thinking processes of aboriginal peoples about numerical problems and structures. Here again his admiration of the cognitive processes of so-called primitive people was evident. The numerical concepts and structures that people around the world use for particular purposes are often elegantly appropriate for the particular task at hand. The article is riddled with dozens of examples of how particular numerical usages are appropriate for their intended purposes; the usages typically are structurally far more elegant than simply applying the abstract, piecemeal, abstruse, content-less western additive system to all numerical problems. It makes no sense, for instance, to count the number of grains of rice for a meal; their overall bulk is what is crucial. And if I add two horses and two people, I may not have four – but two riders. In many contexts it is more appropriate to use such terms as 'a few' or 'many' rather than specific numerals. Or if I happen to break a spear in half, I don't now have two items as such, but a broken spear – a piece of a shaft and another one that has what might be a reusable tip. If a chain of eight links is cut in half I have two chains of four

links each; if I divide each of these, I have four batches of double links – and if the division continues the same way, I no longer have even a semblance of chain but a collection of links (and not even links any more if I divide each of them once again). Adding one to a small group is very different from adding one to a large group; and there are many other instance in which the rigid application of the western fixed, rigid system of counting in integers is by no means always more appropriate, more sophisticated, or more advanced. The article makes clear that to do justice to how people think about quantitative issues it is inappropriate to ask which numbers and operations of the European mathematical system they happen to be using; rather, the issue is what kinds of thought processes they use in dealing with particular concrete problems; what do their thought processes actually achieve? Wertheimer discusses ‘natural groups,’ ‘sensible operations,’ ‘variability,’ ‘approximate quantities,’ ‘arrangements, counting processes, value, and many other issues related to quantitative thinking. Many numerical structures that occur in various cultures permit a variety of conceptions of groups and quantities that are more true to the material being represented.

Another paper that Wertheimer published in 1912 is generally considered to be the article that launched the ‘Gestalt school of psychology.’ It concerned the perception of apparent motion when what is presented to an observer is in fact a succession of static visual stimuli. If, for example, on a white ground two short vertical black lines equidistant on either side from a visual fixation point, separated from each other by a small horizontal distance, are successively exposed with an appropriate very brief time interval between the exposures, the observer may see not a succession of two stationary vertical lines, but one vertical line moving back and forth. If the time interval between exposure of the two lines is too short, the observer sees two simultaneous stationary lines, and if it is too long two successive stationary lines are seen – but with the appropriate time interval between the offset of the first line and the onset of the second, the emergent phenomenon of a single line moving from one location to another (and back again, if the exposures are repeated) is unmistakable. Such stroboscopic motion, which is of course the fundamental process in motion pictures, was already well known in cinema; Wertheimer designated the phenomenon of the perceived apparent motion the phi phenomenon, using the Greek letter phi that is the first unit in the Greek root of that word. In general, what happens when motion is perceived in a pattern of successive exposures of stimuli that are actually stationary? The then-predominant view that complex perceptual experiences are the sum total of their constituent sensations cannot account for the emergence of the perceived motion. The motion cannot be derived simply by theoretically adding together the sensations of the stationary lines. Nor can the perceived motion be due to eye movements of the observer, since it is easy to generate motion in opposite directions at the same time with a stimulus pattern such as a horizontal motion from left to right between two lines exposed just above a fixation point and a simultaneous horizontal motion from right to left between two lines exposed just below the fixation point.

The stimulus arrangements and the temporal relationships of their exposures constitute a striking experience, a Gestalt with certain specific requirements if the observer is to see motion, a Gestalt that cannot simply be decomposed into a

concatenation of associated sensations. Indeed, Wertheimer argued, a pattern of stimulation is required in which certain conditions must be met in the processes in the brain that correspond with the perceptual experience. The brain traces of the two lines must functionally be physically close enough together spatially and temporally that a kind of ‘short circuit’ can occur between the electrochemical field of excitation produced in the visual cortex by the exposure of the first line and the excitation produced by exposure of the second.

Wertheimer’s ground-breaking experiments on the phi phenomenon were performed in the winter of 1911–12 at the University of Frankfurt, where two other young psychologists, Wolfgang Köhler and Kurt Koffka, were his main experimental observers. The three, Wertheimer, Köhler, and Koffka, were to become the recognized leaders in the Gestalt movement in psychology during the following decades.

Gestalt Theory Matures

Wertheimer’s work earned him a faculty position at the University of Frankfurt, where he remained until a call to the University of Berlin in 1916. Then in 1929 he obtained a full professorship back at the University of Frankfurt. Meantime Köhler, first on Tenerife in the Canary Islands and then at the University of Berlin, published extensively on applications of Gestalt theory to perception, to thinking and memory, to problem solving by chimpanzees, and to physical and physiological configurations, and developed major systematic theoretical statements on Gestalt theory. Koffka did many experiments on perception at the University of Giessen and then moved to the United States; he introduced Gestalt theory to the English-speaking world in an influential 1922 paper on perception that summarized much of the Gestalt perception work of the preceding decade, and in 1936 published a lengthy textbook that not only discussed the large corpus of experimental work that had been performed by that time in the Gestalt mode but also developed detailed Gestalt perspectives on social psychology and personality. By the fourth decade of the twentieth century Gestalt theory had become one of the dominant ‘schools’ of European and American psychology and had been adopted by many ‘second-generation’ Gestalt theorists such as Kurt Lewin, Rudolf Arnheim, Karl Duncker, Wolfgang Metzger, and Mary Henle.

Although Wertheimer published relatively little during this period, he continued to have a profound influence on many students and colleagues. Among his few major articles of the 1920s one, on the principles of organization of perception published in 1923, was to have a significant and lasting impact; its principles became part of the discussion of perception in almost all introductory psychology texts down to the present.

How is it, Wertheimer asked, that we perceive a world of meaningful objects in space when all that the brain has to work with is impulses in individual neurons that have been excited by stimulation of our sensory organs? In vision, light rays entering the eye stimulate various elemental cells in the retina to a greater or lesser extent; these cells in turn send all-or-none messages through the neural apparatus via midbrain structures to the occipital lobes of the brain. How does the complex of

differential excitation of the occipital cells get turned into the rich world of visual experience – in which one sees, for example, not a series of 150 dots of a certain brightness and hue, 200 of another kind, and so on, in a disorganized patchwork, but instead a house, and trees, and the sky? What are the principles of perceptual organization? How do piecemeal, unrelated bits of neural excitation become organized into perceived segregated Gestalten, familiar and unfamiliar specific objects organized in space and time?

The 1923 paper contains numerous simple patterns of dots and figures that elegantly show the reader in an immediate demonstration how the various ‘principles of perceptual organization’ operate, and permit the reader even to observe what happens when those principles are set in opposition to one another as well as when they cooperate to generate the same Gestalten. The overarching principle of organization Wertheimer called the ‘principle of Prägnanz’: the organization of any whole will be as ‘good’ as the prevailing conditions allow. All the specific individual principles of organization are, in effect, special cases of the principle of Prägnanz. Among these principles are proximity, similarity, common fate, closure, and habit.

Other things being equal, items that are close together in space and time are more likely to be organized as belonging together in a unit than items that are farther apart. For example, in a horizontal series of dots, if there is a space of two millimeters between the first two, then ten millimeters between the second and third, then two millimeters between the next two and ten between the next, and so on:

•• •• •• •• •• ••

then one sees a pattern of paired dots; if the distances were, say, two millimeters between dots one, two, and three then ten millimeters between three and four and again two millimeters separating four, five, and six, then ten between six and seven, and so on:

••• ••• ••• ••• ••• •••

then the pattern is organized into triads of dots. This principle of proximity, like the other principles, applies not only in vision but in other sense modalities such as audition as well. Thus a succession of pairs of knocks separated in time from one another by longer intervals:

!! !! !! !! !! !!

is indeed perceived as pairs, quadruplets separated by longer time intervals:

!!!! !!!! !!!! !!!! !!!! !!!!

are grouped as quadruplets, etc. Proximity in time works as a principle of perceptual organization just as effectively as proximity in space.

If equally spaced small colored circles are placed in a row, two black, then two white, then two black, then two white, etc.:

● ● ○ ○ ● ● ○ ○ ● ● ○ ○

then the principle of similarity indicates that pairs will be seen. If a series of three loud knocks is followed by three softer ones

then three loud ones followed by three softer ones, all separated by the same time interval:

!!! ... !!! ... !!! ... !!! ...

the result is perception of a succession of triads.

If in a horizontal series of small equally spaced dots suddenly the fourth, fifth, and sixth move upward a few millimeters:

• • • • ↑ ↑ • • • • • •

that set of the fourth, fifth, and sixth dots will, since they are undergoing a ‘common fate,’ be perceived as a group. Comparably, even though different parts of the human body are composed of different visual qualities, the fact that a walking person is perceived as a unit is largely due to the different parts of the body moving together; they are undergoing a common fate.

Parts of the visual field that form a closed unit such as a circle or a square cohere in part not only because of proximity or similarity (if uniformly colored) but also because of the unifying effect of the principle of closure. This principle also applies to incomplete forms, such as a triangle made up of dashed lines or a circle the circumference of which is actually a large number of dots, say twenty-five.

If one becomes accustomed to certain units through practice, such as in cursive writing, then the individual letters can be discerned even if the other principles of organization do not facilitate such units; comparably, if one is presented with a succession of patterns of horizontal lines of dots with diminishing distances between, say, the second and third dots and increasing ones between the first and second throughout the line, starting with distinct pairs (first and second, third and fourth, etc.), then a line in which the dots are actually all equally spaced will still be likely to be perceived in the same pairs as in the series before.

This principle of habit is generally weaker than the others, and tends to lose out to the others if they are allowed to operate. Wertheimer’s 1923 article also presents the results of experiments in which the principles are pitted against each other, showing among other things that the principle of common fate appears to dominate the others.

Among Köhler’s more influential publications that had a major and lasting effect on the psychology of problem solving was a book reporting the results of experiments in which chimpanzees succeeded in the task of obtaining a lure like a banana by using a stick as a tool to reach the fruit that was otherwise out of reach outside a cage, or by building a tower of two or three sturdy boxes (towers which typically were, it is true, somewhat unstable) and climbing the tower in order to reach a banana suspended from the ceiling of a cage. Köhler’s analysis of the chimpanzees’ behavior made clear that the animals understood the physical conditions of the problem, had ‘insight’ into the situation, and were reacting sensibly to it – not just engaging in blind trial-and-error random behavior that other psychological theories of the time had assumed would characterize such behavior. Köhler’s monograph extended the Gestalt work on the psychology of thinking that had been begun by Wertheimer’s early papers, including one in the late second decade of the twentieth century that had presented a Gestalt version of the logic of reasoning.

The Expansion of Gestalt Theory

While Gestalt psychology began and flourished in Germany, it soon expanded worldwide. All three of the original founders of the movement emigrated to the United States, Koffka in the 1920s and Köhler and Wertheimer in the 1930s. Other centers of Gestalt work developed in various other countries such as Italy and Austria, as well as in Japan. By the 1930s the influence of the school was worldwide. Yet the expansion of the school was not only geographic but substantive as well.

Wertheimer had already hinted at the applicability of the Gestalt perspective far beyond psychology, and Köhler had in detail shown its usefulness in physics, in the understanding of field phenomena such as magnetism and electricity.

After his move to the New School for Social Research in New York in 1933 (to escape the Nazi menace), Wertheimer published papers that provided Gestalt analyses of the concepts of democracy, ethics, freedom, and truth. None of these four ideas can, he argued, be understood simply as arbitrarily connected elementary concepts; they all have dynamic Gestalt features that cannot be understood in a piecemeal fashion. In a true democracy, it is not just blind acceptance of the result of a piecemeal vote that is central and essential, but what is crucial are the principles of reason and justice, with respect for and accommodation of minority rights; democracy is a kind of hierarchical structure, with the interacting parts doing what is required of them by the whole. Ethics is not the application of hasty, superficial relativism, but can and should be based on the structural features and roles in a situation, their inner causation, their inner determination. Freedom is not arbitrary absence of constraints, but is a condition of an entire social field, and must be viewed in its function, its role, and its interactions, in its consequences for individual people and for the society as a whole. And truth is not just a property of a proposition comparable to falsehood; truth applies not only to assertions but rather to what people do, in what Wertheimer called the will to do justice to the situations people are in, recognizing the inner connection between truth and justice.

Productive Thinking: The Culmination of Gestalt Theory

The psychology of thinking was Wertheimer's primary concern throughout his career. He lectured on this topic since the second decade of the twentieth century, and published on it occasionally as well. For many years he worked on the manuscript for a book on creative thinking, but he repeatedly revised what he had already written. The final product, entitled *Productive Thinking*, was completed shortly before his sudden death in October 1943; the book was published two years later. It has had a profound influence on many disciplines, including modern cognitive psychology.

The book begins by asking what occurs when, now and then, thinking really works productively, when thinking truly forges ahead. What is the nature of creative thought? Earlier discussions of such processes, Wertheimer argues, seem to cover up the real problems rather than facing them directly. In daily life there are many occasions, including especially in the thinking processes of children, in which there is a

transition from a blind, pedestrian attitude, via the birth of a genuine idea, to understanding in a productive process. What are the conditions favorable to such productive events? What is the difference between good and bad thinking? Traditional logic may be precise and rigorous, but it does not help in attempts to understand what actually goes on when productive thinking occurs. The classic syllogism is incapable of describing how thought actually works in going from several premises to a justifiable conclusion. Sheer examination of processes of definition, comparison, abstraction, generalization, and the like does not provide an understanding of how thinking actually occurs. Comparably, the well-established theory of associationism, or its more recent version, the psychology of conditioning and study of the process of forming connections, with its emphasis on frequency, recency, the role of past experience, trial and error with chance success, learning on the basis of repeated success, and so on, is of little help if one wishes to distinguish between sensible thought and senseless combinations, or to deal responsibly with the productive side of thinking.

Wertheimer examines the nature of truly productive thinking by discussing in detail various specific concrete problems. He typically invites readers to deal with the problem themselves, and often deftly guides readers to the point where they themselves can experience the exhilarating process of achieving insight into the solution of the problem. Successive chapters deal with instances as mundane as finding the area of a parallelogram and other geometric issues through various mathematical puzzles and issues in specific human interactions to such sophisticated arenas as finding the sum of the angles of a polygon and Galileo's discovery of the law of inertia, culminating in how Albert Einstein's thinking led to the theory of relativity (a chapter based on many discussions with Einstein). The final chapter summarizes Wertheimer's characterization of the dynamics and logic of productive thinking. Most of the examples used in these chapters had formed the core of many earlier lectures Wertheimer had presented over the years, and several of them had already been used in earlier publications.

Blind habits, special interests, and certain kinds of school drill, as well as bias, can interfere seriously with what Wertheimer calls genuine, fine, clean, direct, productive thinking processes. Operations such as grouping, centering, and reorganization form an essential part of productive thinking. These operations are not piecemeal but are related to whole-characteristics, are determined by structural requirements of the whole in a sensible way; they are not like a summative aggregation, a succession of piecemeal, chance happenings. Productive thinking consists of realizing structural features and structural requirements of the problem itself, disregarding superficial peripheral features and concentrating on core gaps or disturbances, resulting in appropriate structural grouping and segregation; cognitive operations must be viewed and treated in their structural place, role, and dynamic meaning within the whole situation. Crucial issues concern the relations between parts and their wholes, segregation, grouping, centering, and structural transposability. Productive thinking involves the successful transition from a situation that is murky, confusing, incoherent, and makes no sense into one that is clear, clean, transparent, and understood.

Furthermore, successful productive thinking is a supremely rewarding activity; few pleasures match those contingent on finally understanding, finally having a genuine insight into a problem that at first was recalcitrant and incomprehensible.

The book was reissued in an enlarged edition (containing three new chapters and a series of appendices based on material found in Wertheimer's papers after his death) in 1959, has been translated into Japanese and German, and continues in print. The original edition was widely reviewed, with positive evaluations, not only in psychological journals but in the popular press including the *New York Times Book Review*, with a glowing review by the poet W. H. Auden. It has had a major impact on modern cognitive psychology, especially in research on problem solving during the second half of the twentieth century, with many scholars citing it as specifying the kinds of problems which modern computer models of cognitive processes have to solve. While there has been substantial progress in the understanding of associative processes, there still has been relatively little that goes beyond Wertheimer's analysis of genuinely productive thought.

The Legacy of Gestalt Theory

The experimental work of the Gestalt theorists and their students on perception, thinking, memory, personality, and social psychology made the Gestalt approach an accepted part of Western psychology by the middle of the twentieth century. During the second half of that century, as was true of the other early schools of psychology, interest in it as a school waned, as psychologists concentrated more on specific circumscribed areas of research rather than on broad, overarching theories. But by late in the century, the utility of the Gestalt approach was once again reemphasized in a wide range of domains, from the psychology of art through psychopathology and social psychology to modern cognitive science and visual neuroscience, as well as education. The days of connectionistic associationism, blind conditioned processes, exclusive concentration on behavior rather than mental events, were over. It is now widely recognized that there are few if any psychological – or physical or neurological – processes that are no more than a mere sum of their constituent elements, and that most natural wholes are in fact dynamic entities in which the parts are not inert but are actually in complex internal interaction with one another – and in which the characteristics of the whole

do indeed determine the nature and structure of its parts. This recognition can in part be attributed to the rigorous and ingenious creativity of Max Wertheimer.

Glossary

Decorative arts Also called crafts or applied art, traditionally refers to decorated functional objects, such as furniture, ceramics, clothing, and glassware. These are usually afforded less status than the fine or high arts.

Faustian bargain The term refers to the legend of Faust in which the title character offers his soul to the devil in exchange for knowledge and worldly pleasures. The term has come to represent any deal that an individual makes to give up something important to satisfy a desire for something else.

Good ole boy networks A slang term for informal networks of men who help each other in professional, social, economic, and political ways, thereby excluding others.

High arts Also known as fine arts, traditionally refers to art that has no function other than esthetic. Although some restrict this term to the visual arts such as painting, sculpture, architecture, photography, and printmaking, more contemporary usages include music, dance, theatre, and literature.

Pen names Also called noms de plume, or pseudonyms, these are invented names which are used by writers to disguise their real identities.

Brief Background and History

In the lists of eminent artists, musicians, writers, scientists, inventors, entrepreneurs, etc. the names of women are in the minority. Why? Are women less creative, or have they just had fewer opportunities and more obstacles to overcome? Women's creative productivity from earliest times belies the contention that women are inherently less creative, but an examination of the obstacles that they have had to overcome to produce publicly recognized creative work gives a good picture of why women's creativity has been limited in certain areas.

From ancient times, women have been involved in creative endeavors, from cave paintings, woven baskets, pottery, and clothing, to songs and poems. In nontechnological cultures, where the arts are an integral part of daily life, women have always been involved alongside men and children in the creation of artifacts that are both useful and decorative. There is evidence that there were women artists, writers, musicians, healers, physical scientists, inventors, and mathematicians in ancient Egypt, Rome, Greece, China, Japan, Mesopotamia, India, and other cultures.

As cultures developed into more complex and hierarchical systems, education became more formalized, and access to education was limited. The production of purely decorative art became something that only people of leisure could pursue. There began to be a separation between art that was purely aesthetic and the decoration of practical objects, with the result that the former was more valued than the latter. For example, during the Middle Ages in Europe, educated women were those in the upper class and nuns; the upper class women usually produced embroidery, and the nuns usually produced biblical illuminations. Lower classes of women continued to decorate their homes and clothing, but these were not valued and preserved as art. Thus, access to education, a privilege of males in many cultures, became a gateway to the more prestigious arts such as literature, music, drama, and visual arts such as

painting and sculpture. Women were more likely to be involved in decorative arts, such as ceramics, glassware, furnishings, and clothing design, which were useful but had lower status.

Societal Norms

In 1982, a comic strip, Frank and Ernest by Bob Thaves, showed the title characters standing in front of a theater poster advertising a Fred Astaire film festival as the female character in the strip told them, "Sure, he was great, but don't forget that Ginger Rogers did everything that *he* did, backwards and in high heels." This comic strip illustrates the concept that women who have reached a level of eminence have had to work harder and be better to achieve than men have.

Because the access, expectations, and opportunities for females have historically been limited in most societies, the few women who have achieved success have done so in spite of great odds. For example, Elizabeth I, arguably the greatest monarch of England, was only allowed to succeed her father to the throne because he failed to produce any legitimate male heirs. Yet her success as a monarch didn't do much for women's rights. Almost 300 years later, Harriet Beecher-Stowe was not allowed to speak on her lecture tour through Great Britain. British culture at the time expected women to limit their public exposure and not speak publicly. Women were allowed to sit in lecture halls if they sat behind wooden lattices in special 'ladies' galleries.' So, Beecher-Stowe sat silently in a gallery and let her husband and son speak for her. Other women had to hide under or behind furniture to listen to lectures. The hardships, trials, and sacrifices that women have had to experience in order to express their talents are many and daunting. Some areas that will be discussed include education, family and peer support, appearance, the demands of motherhood, the gatekeepers, and works falsely credited, not credited, or stolen.

Education

One of the many barriers for women has been the inaccessibility of the education they need to progress in many fields, including the sciences. Only nine women have won Nobel Prizes in science compared to more than three hundred men.

In Europe, most high schools for girls were nonacademic finishing schools until the 1920s. Thus, women were not only prevented from enrolling in universities, they were also denied the educational training to prepare them to enter universities. Mathematician Emmy Noether (1882–1935) was prevented by German law from enrolling at the university, so, like other females who desired a career, she attended a teacher training institute. However, at age 18, she got permission from some professors to audit classes at the local university. Only one of two women auditing classes in a university of a thousand men could not have been comfortable. Eventually, the laws changed, and she was able to enroll for credit. Due, in large part to her ability to work with her father, a mathematics professor, and his mathematician friend, Max Gordan, Noether was able to submit a thesis at age 25 that won her highest honors. However, this did not open the doors for her as it would have for a man. For the next eight years, she taught at the university without pay. As her father's health worsened, she gradually took over his duties. She had to teach, submit articles, and even edit a mathematical journal under pseudonyms. Working without pay was not unusual – Marie Curie also taught at the university level for years without pay. In fact, in the United States, women university professors often taught without pay until the 1950s.

In the United States, in the late 1800s, some major universities established separate facilities for women when it became clear that the pressure to enroll women was increasing. Columbia University, which had allowed women to take examinations but not attend lectures, established Barnard College as a female affiliate institution in 1889. Harvard followed soon after with the opening of Radcliffe in 1894. Other universities avoided admitting women by following suit. The idea of separate but equal, which US courts would later rule is inherently unequal as applied to racial segregation, was allowed to stand for years in regard to the separation of the genders. Thus, females were prevented from studying with the most outstanding researchers, Nobel Prize winners, and leading professors who were being drawn to the more prestigious male institutions. Women university professors taught without pay in the United States until the 1950s.

In other parts of the world, females in third world countries are often denied any education at all; they are also denied adequate food, hospital care, or even life if they are born in some parts of the world to a family that desires a son. Thus, the severity of discrimination around the world ranges from infanticide to unequal pay. The historical unequal access to education has prevented many women from achieving the same levels as men.

Family and Peer Support

In addition to a good education, talented children need the support and dedication of their families to achieve eminence,

especially in certain fields that require early and intense specialized training. Benjamin Bloom and his colleagues studied the development of 120 individuals who achieved world-class status in athletics, the arts, and science. They concluded that the families of these highly talented individuals supported their training, often at great sacrifice to themselves and the rest of the family. These sacrifices include financial commitments and even separating the family so that the talented child can work with the best trainers, coaches, etc. When this happens, there is almost always one child who is supported, and historically, the chosen child has been a male. The benefits to the chosen child of being designated special include both the resources that such a designation brings as well as the psychological boost.

In addition to family support, there is the critical support to nascent creators from friends and colleagues. When those friends and colleagues can promote each others' careers, an important network can be established. In the United States they are called 'Good Old Boy Networks' emphasizing the elements of friendship and maleness of the members. Such networks serve to support and help members professionally, while there is *de facto* exclusion of nonmembers. Much has been made of the opportunities afforded to men who play golf with the boss, belong to male-only social clubs, or take male-only trips because of the opportunities that are discussed in such informal settings. Because women have not traditionally been in places of power, corresponding women-only social networks have not been as helpful. On a more formal level, the opportunities for males to study and work with the most eminent leaders in their fields have undoubtedly given the budding creators both the benefits of their older men's expertise and the value of their social networks. For example, a view of the network of Nobel Prize winners shows that Nobel winners have usually studied with Nobel Prize winners. Women have traditionally been denied access to such training and networks.

Appearance as a Complication

Another complication for women is the emphasis on their looks. The possession of good looks or the lack thereof has a much bigger impact on women's success in various fields than it does for men. This is a complicated situation because although good looks can promote a woman in some areas, they can also be limiting in others.

The global proliferation of blonde jokes demonstrates the ubiquitous nature of the stereotype that beauty and intelligence cannot coexist. Although potentially applicable to both genders, the jokes are almost always about women, and specific to blondes. Common elements of the jokes are a beautiful but dumb woman who is typically promiscuous and misunderstands common sense facts or simple life processes. How such a stereotype affects women's attitudes and opportunities is hard to measure, but there are many examples of beautiful women who are not taken seriously.

For example, Hedy Lamar was considered one of the most beautiful women in the world in the heyday of Hollywood, and her beauty undoubtedly enabled her to become a famous

actress. Yet, her image as a beauty masked her quick mind, as the stereotype of a beautiful woman has often implied that she must also be dumb. Hedy recognized this dichotomy in her oft-quoted statement, "Any girl can be glamorous. All you have to do is stand still and look stupid."

Hedy experienced this stereotype in her youth in Vienna. Hedy's much older first husband was an Austrian munitions manufacturer who did research on control systems. In the years leading up to the Second World War, he and his colleagues frequently discussed this information freely in front of the very young and lovely Hedy believing that she could hardly be interested in or understand such technical discussions. However, Hedy was listening and understanding. Years later, she divorced her husband and moved to Hollywood. When the US went to war with Japan and Germany, she and a musician friend, George Antheil, were determined to do what they could to stop the Nazis. Hedy recalled what she had learned about German weapon systems and combined that knowledge with George's understanding of the workings of a player piano to devise a system to protect US radio-guided torpedoes in the Second World War from being intercepted by the Nazis by frequency hopping. However, the US Naval Department would not take an idea proposed by a beautiful actress and a musician seriously, even when that idea had the support of the newly established National Inventors Council. Hedy was encouraged to support the war effort by selling kisses to promote the sale of war bonds, and she did so very successfully.

Although Lamarr and Antheil patented their idea in 1942, the invention was not used in US military ships until 20 years later, after the patent had expired. However, the value of the invention extends beyond military use and is considered the precursor of other inventions that depend upon spread spectrum technology – things such as traffic signals, cellular phones, pagers, wireless Internet, and the Milstar Defense Satellite.

The Demands of Childbirth and Child Rearing

One of the biggest challenges to creative women is that of balancing the demands of childbirth and child rearing with the demands of creative productivity. Of course, it can be argued that many women have focused their creativity into creating nurturing homes and raising their children, but these efforts are not recognized as public creative achievements, nor do they satisfy the creative drive of some women who aspire to express their creativity in other ways. Kate Chopin wrote of this struggle in the novel *Awakenings*.

So, many women, like Camille Claudel and Mary Cassatt, eschewed child rearing in order to dedicate themselves to their art. Explaining this point of view, Austrian artist Maria Lassnig, explained:

When I was young, I was clever enough to know that if I got married or had children, I would be eaten. I would be sick if I couldn't paint, and I would be schizophrenic because I would have wanted to do both [paint and have a family]. So I renounced it. I don't understand young women who have a big family and want to make art. I don't think it is possible. (Saner, 2008)

Yet, at many times in history and in many cultures the option to remain single has not been available to women. Men have not typically had to make such a choice.

As Sharon Bertsch McGrayne observed in *Nobel Prize Women in Science* about the dilemma for women scientists, "They were expected to remain single, but they needed husbands in order to gain access to research laboratories." Women artists were in no better position to support themselves while single and pursue their art.

Some women, like Sylvia Plath and J. K. Rowling, who have attempted to have both a family and creative career, took time from their sleep to write in the early mornings while their children slept. Such options are not available in all creative endeavors. For example, a 2008 study by Dawn Bennett found that women professional musicians are more likely to teach than perform because of the difficulties of balancing family commitments with a performing schedule. Thus, the term 'Mommy Track' has been coined to explain the career options that many women take to have flexibility in their work schedule or work fewer hours in order to raise their children. Women who take these options usually find that their career options are temporarily or permanently stunted.

Two painters who were sisters, Berthe and Edna Morisot, chose different ways to address the tension between the traditional female role of wife/mother and artist. The sisters studied art and painted together until Edna married and had children, and she no longer had the time and energy to dedicate to painting. However, Edna's letters to her sister revealed that she missed the painting. Perhaps that is why Berthe continued to pursue her art after her marriage and the birth of her children. Also, Berthe was fortunate in that she married a man who had enough wealth and artistic interest, as the brother of the artist Manet, to encourage and enable her to continue to work on her art.

The Gatekeepers

In praising the art of Camille Claudel, art critic Octave Mirbeau declared her, "A revolt against nature: A woman genius." In writing this, he offered her the highest praise and emphasized how rare such talent was assumed to be in women. Indeed, it was rare for women to be featured in art expositions or other creative venues. This was due, in part, to the few women who followed such careers, but it was also due to the limits that were placed on women and their work. Gallery owners, symphony directors, publishers, faculties, corporate boards, journal editors, producers, etc. have controlled not only what work is promoted, but also whose work is promoted. Consequently, even those females who have managed to do great work have not always had the opportunity to disseminate it. So, when possible, many chose to put male names – either real or imaginary – on the work to have it published.

Work Falsely Credited, Not Credited, or Stolen

As in the case of Emmy Noether, work done by women is often credited to a man in order to get published. Some

of Camille Claudel's early sculptures were signed by Rodin. The first woman inventor in the American colonies, Sybilla Masters, invented a method of making cornmeal out of maize and saw her husband awarded the patent by the English courts for the new invention "found out by Sybilla his wife." In some cases, such as that of George Sand, George Eliot, and Isak Dinesen, female writers invented male pen names in order to get published and sell books. In other cases, such as that of scientist Rosalind Franklin, their work was used without credit. In still others, such as the collaborative work of Frieda Robschheit-Robbins and George Hoyt Whipple on the cure for pernicious anemia, only the work of the male was acknowledged; only Whipple was awarded the Nobel Prize for physiology in 1934, although he shared the money with Robschheit-Robbins.

Because for so many years it was difficult for women to have their work accepted, they were willing to have their work credited to real or fictional men, or powerless to prevent it. Even today, some women writers, such as J. K. Rowling, prefer to use initials to publish rather than try publishing under a clearly female name.

The Price

Phyllis Chesler queried in *Letters to a Young Feminist* said:

Some say that Plath, Woolf, and Claudel were 'mad' geniuses who'd have ended up the same sad way even if they'd each been nourished in a woman-loving family and culture. How can such cynics be so sure?

It is certainly hard to predict how things would have been different for female creators if they had been allowed access to education, in societies that expect and encourage female creative productivity, and with families, both through birth and marriage, that nurture and support creative endeavors. The few cases of highly creative productive women have illustrated how they were able to obtain the training they needed in spite of the odds, find at least one supporter, and persist at their work. Yet, even the most successful have found that their success had a price. In the cases of Plath, Woolf, and Claudel, the price may have been sanity, though it is not clear what relationship, if any, their creativity had to their mental problems. Other creative women gave up having a marriage or children, female friends, the approval of their families, the comforts of a supported life, the credit for their work, the respect of their peers, as well as their own health and well-being. Although all choices in life require sacrifices, so many of the sacrifices that creative women have made and continue to make were and are

unnecessary. One could only conjecture how much more beautiful, disease and problem free, and easier to live in our world would be if all creative individuals were allowed to pursue their passion to create.

Virginia (Stephen) Woolf 1882–1941

Novelist and essayist

Author of *To the Lighthouse*, *The Waves*, and *A Room of One's Own*

M F Ippolito, Bowling Green, OH, USA

© 2011 Elsevier Inc. All rights reserved.

This article is reproduced from the previous edition, volume 2, pp. 709–715, © 1999, Elsevier Inc.

English novelist VIRGINIA WOOLF is acclaimed for her innovations in novelistic structure and for a writing style perhaps best represented by her fifth novel, *To the Lighthouse* (1927). Although Woolf considered her nonfiction efforts secondary to her novels, she was a productive and influential essayist. Her best-known essay, *A Room of One's Own* (1929), argues for financial security and independence as essential to women writers. In the preponderance of her essays, Woolf attempted to detail the English novel as re-formed by stream-of-conscious writers such as herself. Plagued by mental illness from childhood, Woolf ended her own life in 1941.

Virginia Woolf. Used with permission of Frederick R. Koch Collection, The Harvard Theatre Collection, The Houghton Library.

Background

Virginia Stephen (Woolf) was born on January 25, 1882, in Victorian England into an upper middle-class family. Her father, Leslie Stephen, was a distinguished literary figure who developed friendships with many members of the literary elite, such as Thomas Hardy and Henry James, childhood acquaintances of Woolf. Some years later, Woolf was a distinguished member of another group of intellectuals that came to be known as the Bloomsbury Group (named for the district in London to which Woolf and her sister and brothers moved in 1904 after Leslie Stephen's death). The Bloomsbury Group originated when Woolf's older brother invited friends he had made at Cambridge University to the Stephen siblings' residence. Discussions at informal Thursday evening gatherings, which began in 1905, ranged over a number of topics including history, philosophy, art, sexuality, and literature. In addition to Woolf, other well-known members among the original participants in the Bloomsbury Group included Leonard Woolf (her future husband and a novelist, political activist, author of political treatises, editor, and publisher), biographer Lytton Strachey, economist John Maynard Keynes, and novelist E. M. Forster.

To her father's delight, Woolf expressed an interest in becoming a writer during her childhood. Among her first literary efforts was a household newspaper, *The Hyde Park Gate News*, named for the longtime Stephen family residence. This newspaper was a compendium of household events, essays, and Woolf's first fiction efforts, with issues dating from shortly after her ninth birthday until just weeks before her mother's death in early 1895. The passion for writing that began during Woolf's childhood persisted throughout her lifetime. For Woolf, however, writing was a double-edged sword. She characterized writing as a pleasurable, essential, and consuming aspect of her life but, also, as analogous to coal mining, subduing a python, and galloping at fences. Woolf wrote in her diary when she was 39 years old: "I shall never write out all the books I have in my head, because of the strain. The devilish thing about writing is that it calls upon every nerve to hold itself taut" (v. 2, p. 128–129).

The strain of writing that Woolf spoke of was arguably attributable to the task she set herself. Almost without exception, the novels of her contemporaries continued in the realistic/materialistic style of Charles Dickens and Jane Austen—relying on descriptions of what characters said, did, and wore as primary components. In "The Art of Fiction," written the same year as *To the Lighthouse*, Woolf hoped English novelists would "cut adrift from the eternal tea-table and the plausible and preposterous formulas which are supposed to represent the whole of our human adventure. . . . Then the novel . . . might become a work of art" (p. 112).

The novel Woolf envisioned would chart the mental as well as the material lives of the characters. As early as 1908, Woolf recorded in her early journals (published as *A Passionate Apprentice: The Early Journals, 1897–1909*) the intent that her writing reflect "all the traces of the mind's passage through the world and achieve . . . some kind of whole made of shivering fragments" (p. 393). And in "Modern Fiction," Woolf wrote:

Life is not a series of gig lamps symmetrically arranged; but a luminous halo, a semi-transparent envelope surrounding us from the beginning of consciousness to the end. Is it not the task of the novelist to convey this varying, this unknown, this uncircumscribed spirit, whatever aberration and complexity it may display, with as little mixture of the alien and external as possible? (pp. 154).

Although it was clear to Woolf that the prevalent realistic novel was inadequate, it was, as yet, unclear what novelistic forms might accommodate her new kind of novel and how the English language might be stretched to capture the dynamics of mental processes. Whereas Woolf admired Dorothy Richardson's and James Joyce's efforts to expand the novel to include the workings of the mind, she felt the novels of

these authors were limited in that each provided access to the uncontradicted psychology of a single character. Eventually Woolf constructed stream-of-consciousness novels that embodied a shifting chorus of consciousnesses so the reader knows what the characters think of the unfolding events and each other.

She married Leonard Woolf on August 10, 1912. Throughout their 29-year marriage, Leonard was meticulously solicitous of Woolf's health and acted as her editor and sole prepublication critic. He also collaborated with Woolf in the 1917 establishment of the Hogarth Press (named for Hogarth House where the Woolfs resided from 1915 to 1924). The Woolfs' primary intentions were that the press would free Woolf's efforts to re-form the novel from being subject to the approval of established, often conservative, publishers and publish works of literary merit that other publishers declined. The press succeeded in both respects. In England, Woolf's short stories, essays, her third and following novels, and the second and later editions of her first two novels all appeared with the Hogarth Press as publisher. Further, the press published Katherine Mansfield's short story "Prelude," short fiction and nonfiction works by E. M. Forster, the poetry of Robert Graves and Herbert Read, was the first publisher in England of "The Waste Land" and other poems by T. S. Eliot, and was the sole English publisher of all but one of Sigmund Freud's works from 1920 to 1938. The Hogarth Press was also intended to provide Woolf with therapeutic work to fend off or assist her recovery from mental collapse.

Woolf suffered a number of nervous breakdowns, which included alternating periods of debilitating depression and mania with accompanying suicide attempts, violence toward family members and nurses, and hallucinations. It is likely that she suffered from bipolar disorder (manic depression). Woolf's first bout of what she referred to as madness occurred shortly after her mother's death. This and Woolf's subsequent breakdowns, including one shortly after her marriage, were often followed by extended periods of convalescence, with Woolf estimating that she had lost five years of her life to insanity. Woolf's letters to her husband and sister before her suicide indicate she was fearful of impending insanity, from which she might not recover. She committed suicide by drowning herself (having forced a large stone into her coat pocket) in the river near the Woolfs' country home on March 28, 1941.

Woolf's writing legacy includes 10 novels, numerous short stories, a play, a biography, and several volumes of essays. Woolf's first publication—an unsigned review published several days before her 23rd birthday—followed a lengthy writing apprenticeship. Her last novel was completed 1 month before her death (and published posthumously).

The Writing Apprenticeship

From childhood, Woolf engaged in a self-assigned writing apprenticeship. Her surviving diaries and correspondence document her writing ambitions, practices, and developing philosophy of literature, and they chart the progress of this apprenticeship. Woolf's intent was that her diaries be a place to practice her craft and collect observations she might

incorporate in her fiction. A July 30, 1903, entry—which preceded her first publication by several months—recorded her intent that her early journals

serve for a sketch book; as an artist fills his pages with scraps and fragments . . . so I take up my pen and trace here whatever shapes I happen to have in my head. It is an exercise—training for hand and eye (pp. 186–187).

Woolf continued to use her diaries to practice her craft, writing on April 20, 1919, by which time she was a well-known essayist and had finished her second novel, that she believed "the habit of writing . . . for my eye only is good practice. It loosens the ligaments" (v. 1, p. 266). In the same entry, Woolf identified her diaries as a receptacle for observations to be used in her fiction; these volumes were

to resemble some deep old desk or capacious hold-all, in which one flings a mass of odds and ends. . . . I should like to come back . . . and find that the collection had sorted itself and refined itself and coalesced . . . into a mold transparent enough to reflect the light of life and yet steady, tranquil, composed, with the aloofness of a work of art (v. 1, p. 266).

Woolf's writing apprenticeship included a reading program. As was customary for girls of her socioeconomic class, Woolf had little formal education; but she did have access to her father's vast library. Leslie Stephen was enthusiastic about sharing his books with the daughter who would be a writer; although by the time Woolf was 15, her father expressed concern regarding the volume of his daughter's reading. Notations in her early journals indicate that, during a 6-month period, the 15-year old Woolf read 59 volumes of biographies, novels, history, and essays. Woolf regularly tested her ability to grasp the contents of her reading in discussions with her father and, later, with fellow members of the Bloomsbury Group. Clearly, Woolf placed a high value on extracting the essences of the books she read. In a 1926 lecture at a girls' school, published in 1932 as "How Should One Read a Book?," she stated:

To receive impressions with the utmost understanding is only half the process of reading. . . . We must pass judgment upon these multitudinous impressions; we must make of those fleeting shapes one that is hard and lasting. . . . Continue reading without the book before you. . . . Hold one shadow-shape against another. . . . Read widely enough and with enough understanding to make such comparisons alive and illuminating (pp. 241–242).

As with her diaries and writing, Woolf recognized a connection between her reading program and writing ability. For Woolf, reading enabled familiarity with the possibilities and peculiarities of the English language and an understanding of the relation between author and readers.

Eventually, Woolf's writing ability, her commitment to reading critically, and an acquaintanceship with a journal editor led to her first publication; an unsigned review in the December 14, 1904, issue of *The Guardian*. Woolf's excitement at subsequently becoming a regular contributor to several literary journals quickly gave way to disillusionment. She came to see assigned essays as failing to challenge her intellectually and as taking time away from novel writing. However, she continued to critique what she read informally in her diaries and

correspondence and to publish occasional reviews. Woolf also retained a lifelong interest in writing essays for which she could pick the topics, a concession many editors were eventually willing to make, in light of her growing fame as a novelist and critic.

A final aspect of Woolf's writing apprenticeship is her short stories, which she referred to as sketches—akin to the sketches prepared by an artist contemplating a complex painting or the pilot studies of a scientist. While completing her first two novels, *The Voyage Out* (1915) and *Night and Day* (1919), which were primarily materialistic in style, Woolf wrote a number of sketches experimenting with the lyric and essayistic limits of English and the employment of alternative perspectives and revised plot forms. Woolf envisioned her third novel, *Jacob's Room* (1922), as an extension of the techniques and forms developed in three of these sketches. The writing experiments continued; in a July 30, 1925, diary entry, just prior to beginning to write *To the Lighthouse*, Woolf recollected: "My summer's wanderings with the pen have . . . shown me one or two new dodges for catching my flies. I have sat here like an improviser with his hands rambling over the piano" (v. 3, p. 37).

The Writing of *To the Lighthouse*

For Woolf, novels frequently originated with a scene. She wrote in "A Sketch of the Past" that

Scenes . . . are not altogether a literary device—a means of summing up and making a knot out of innumerable little threads. . . . A scene always comes to the top; arranged; representative. This confirms me in my instinctive notion . . . that we are sealed vessels afloat upon what it is convenient to call reality; at some moments, without any reason, without an effort, the sealing matter cracks; in floods reality; that is a scene . . . I almost always have to find a scene; either when I am writing about a person . . . or when I am writing about a book (p. 142).

Woolf would later write in "A Sketch of the Past" that the idea for *To the Lighthouse* came

in a great, apparently involuntary, rush. One thing burst into another. Blowing bubbles out of a pipe gives the feeling of the rapid crowd of ideas and scenes which blew out of my mind, so that my lips seemed syllabbling of their own accord as I walked (p. 81).

On May 14, 1925, Woolf recorded in her diary the scene from which this novel emerged:

This is going to be fairly short, to have father's character done complete in it, and mother's, and St. Ives, and childhood. . . . But the center is father's character, sitting in a boat, reciting "We perished, each alone," while he crushes a dying mackerel (v. 3, pp. 18–19).

Once one has gotten hold of the scene that is the germ for a work of art, "one must hold the scene . . . in a vise and let nothing come in and spoil it" says the painter who is a character in *To the Lighthouse* (p. 201). The next step for Woolf was to devise a novelistic form appropriate to the germinal scene, a form that would not spoil it.

To the Lighthouse is the story of the Ramsay family at their summer home—not unlike St. Ives where the Stephen family summered until the death of Woolf's mother. Mr. and Mrs. Ramsay are modeled on Woolf's parents. Among the Ramsay's

guests are a painter named Lily Briscoe. There are two parallel stories in this novel: the first about a postponed boat trip to the lighthouse and the second about Lily's struggle with the composition of an abstract painting.

The form of *To the Lighthouse* is a three-part structure, which Woolf depicted schematically in her notebook as two rectangles joined by a narrow passageway. Per Woolf's July 20, 1925, diary entry, this novel was to be about a

father and mother and child in the garden, the death, the sail to the lighthouse. . . . When I begin it I shall enrich it in all sorts of ways, thicken it, give it branches and roots which I do not perceive now. . . . I conceive the book in three parts: 1. at the drawing room window; 2. seven years passed; 3. the voyage (v. 3, p. 36).

The first part of the finished novel, "The Window," records the happenings in and around the Ramsay's summer home. The next day's trip to the lighthouse is canceled because Mr. Ramsay anticipates poor weather; Lily is unable to solve the problems of her painting of Mrs. Ramsay. The second, passageway, part of the novel, "Time Passes," records the passage of 10 years during which Mrs. Ramsay dies. In the third and last part, "The Lighthouse," Mr. Ramsay and his children return to their summer home and Lily Briscoe is again a guest. The trip to the lighthouse finally takes place—with Mr. Ramsay reciting poetry while piloting the boat; meanwhile, Lily Briscoe resumes work on the unfinished abstract painting she abandoned 10 years earlier. The novel ends as the expedition reaches the lighthouse and Lily is able to successfully resolve the problems of her painting.

Once Woolf had settled on the form of her novel, she shifted her attention to its microstructure. For example, Woolf intended that the rhythms of the sea be heard throughout this novel. In *To the Lighthouse: The Original Holograph Draft*, Susan Dick indicated that Woolf began each writing session by rereading what she had written to refresh her memory and "help start a particular rhythm in her mind" (p. 14). Woolf may have also read *To the Lighthouse* aloud to ensure it had the right sound. In *Recollections of Virginia Woolf*, a cook hired by the Woolfs in 1934 recalled hearing Woolf talking to herself while taking a bath:

When Mr. Woolf saw that I looked startled he told me that Mrs. Woolf always said the sentences out loud that she had written during the night. She needed to know if they sounded right and the bath [room] was a good, resonant place for trying them out. He was so used to hearing her talk to herself in this way that he did not notice it at all (pp. 155–156).

In *To the Lighthouse* and her other experimental novels, Woolf intended that the words she wrote carry meaning and convey atmosphere (e.g., the ever present sound of the sea) and the moods of the characters. The writing of a provisional draft of *To the Lighthouse* was accomplished between the latter part of 1925 and the fall of 1926. The commitment of the constructed novel to paper initially progressed rapidly. On February 23, 1926, Woolf recorded in her diary:

At last, at last, after the battle of *Jacob's Room*, that agony—all agony but the end—*Mrs. Dalloway*, I am now writing as fast and freely as I have written in the whole of my life, more so—20 times more so—than any novel yet (v. 3, p. 59).

Perhaps Woolf's ease in writing his novel can be explained. Although she claimed she had to solve the problems of *Jacob's Room* (1922) as she wrote it—because she was initially unsure of her destination—and hoped to plan *Mrs. Dalloway* (1925) more thoroughly, *To the Lighthouse* (1927) was outlined in detail some time before she began to record it. On June 14, 1925, several weeks before she wrote the first words of this novel, Woolf commented on how extensively she had already planned it, fearing she had “thought [it] out perhaps too clearly” (v. 3, p. 29). Curiously, it appears Woolf devoted not less but increasingly more effort to the prewriting planning of each successive experimental novel.

By September 5, 1926, Woolf worried in a diary entry that *To the Lighthouse* might “run too fast and free, and so be rather thin” (v. 3, p. 106). Eight days later on September 13, 1926, Woolf's diary indicated:

This is the greatest stretch I've put my method to, and I think it holds. By this I mean that I have been dredging up more feelings and character. . . . But . . . until I look at my haul this is only my feeling in process (v. 3, p. 109).

Three days later, on September 16, 1926, the first draft was completed. Now the questions regarding the quality of her “haul” that had crept into preceding diary entries became paramount during revision and rewriting.

Earlier, while working on her previous novel, *Mrs. Dalloway*, Woolf had described revising in her diary as “the duller part of the whole business of writing, the most depressing and exacting” (v. 2, p. 4). Although she had written *To the Lighthouse* relatively quickly, its revision presented some difficulty. On November 23, 1926, Woolf's diary indicated:

I am re-doing six pages of *To the Lighthouse* daily. This is not, I think, so quick as *Mrs. Dalloway*; but then I find much of it very sketchy and have to improvise on the typewriter. . . . My present opinion is that it is easily the best of my books (pp. 117–118).

Leonard Woolf read the revised version on January 23, 1927, and pronounced it a masterpiece; Woolf then completed her revisions in March of 1927. The publication of *To the Lighthouse* on May 5, 1927, did not represent an end to Woolf's writing experimentation but, rather, the beginning of a whole new series of experiments that culminated in what is perhaps Woolf's most innovative, although not universally critically accepted, novel, *The Waves* (1931). Later she attempted a novel-essay, which was eventually separated into a novel, *The Years* (1937), and a book-length essay, *Three Guineas* (1938).

The development of *To the Lighthouse* was guided by the intuition of a scene. On the heels of this “aha” experience followed a series of incremental discoveries. First, Woolf constructed an appropriate novelistic form. The constructed form was then used to constrain the selection of language to delineate aspects of the scene. Ultimately, the process of revision, a meticulous reconsideration of the multiple problem solutions that constituted earlier drafts of *To the Lighthouse*, served as a final constraint—the last tightening of germinal scene, novelistic form, and language, to ensure integrity of fit. Her creativity encompassed the large moment of the seemingly instantaneous appearance of a unifying scene as well as the innumerable small moments of incrementally evaluating and constructing nested constraints of this scene.

Woolf's novels clearly benefited from the conscious refinement of her writing, reading, and critical skills. Her writing practices indicate that she never completely relinquished her status as an apprentice; she continued to read extensively, challenge her ability to critically evaluate what she read, and practice writing. Woolf's creativity resulted from the interaction of large and small discoveries—a blending of emergent scenes, purposefully developed writing craftsmanship, and novelistic forms developed via experimentation—against the backdrop of an enduring passion for her art and a longstanding ambition to re-form the novel to capture the dynamics of mental life.

William Wordsworth 1770–1850

Poet

Author of *The Prelude*, *Lyrical Ballads* (co-published with Samuel Taylor Coleridge), and *The Excursion*

WILLIAM WORDSWORTH, *English Lake poet, is revered as a major literary figure and early leader of Romanticism. Ranked with Shakespeare and Milton by Coleridge and later by Matthew Arnold, Wordsworth's radical self-consciousness, intense naturalism, interest in the lives and speech of common people, and strong sense of poetic vocation transformed the subsequent development of poetry and poetics. Remembered today as the supreme nature poet, Wordsworth was also a poet, as Keats observed, of human suffering who could "think into the human heart." He was vitally interested in the development of the imagination. As he wrote in his autobiographical masterpiece, The Prelude, "the mind of man" is "the main region of my song."*

Portrait of William Wordsworth, 1806. Used with permission from The Wordsworth Trust, Dove Cottage.

Background

Wordsworth was born April 7, 1770, in Cockermouth, a village in the English Lake District, an area whose "craggs, and forest glooms, and opening lakes" inspired in him a deep love for nature. He was the second child of five born to Ann and John Wordsworth who both died by the time that he was 13 years old. After a period of formal education at Cockermouth, Hawkshead, and Cambridge (St. John's College), youthful walking tours on the Continent, and a sojourn in France during the French Revolution that included a love affair resulting in the birth of an illegitimate French daughter, most of his life was spent in his beloved Lake District in the company of his extraordinary sister Dorothy and his exemplary wife Mary and their children.

Although it is probably often the case that a creative person's quality of productivity is uneven, with periods of

breakthroughs and exceptional generativity interspersed with dryer, less productive periods, in Wordsworth's case a decline in the quality of the poetry written in his later years has received much critical comment. His early work and youthful democratic zeal have met with much greater contemporary critical approval, whereas the more conservative political views of his mature years have been viewed by some as something approaching a moral lapse. Certainly the poetic creativity of his youth was stunning, and to some extent the mature Wordsworth is doomed by comparison with the romantic figure of the poet as a young man, engaged by the French Revolution, alienated from his unimaginative, stodgy relatives, and in deep passionate communion with nature and sensory experience.

Readers and critics alike today may find it harder to admire the mature Wordsworth, worried about the financial responsibility of a large household, imposing upon his children his ideas of what they should do with their lives, and reshaping his poems to be more orthodox. It is ironic that though today Wordsworth's later work is not critically celebrated, in his own time his reputation as a poet increased as he aged. DeQuincy wrote, "Up to 1820 the name of Wordsworth was trampled under foot; from 1820 to 1830 it was militant; from 1830 to 1835 it has been triumphant."

Wordsworth experienced a period of exceptional poetic productivity from 1798 to 1808, including the *annis mirabilis* (1798), in which he and Coleridge published *Lyrical Ballads*, a volume of historic literary significance opening with Coleridge's "Ancient Mariner," and closing with Wordsworth's "Tintern Abbey." In 1800 he published the second edition of *Lyrical Ballads*, including his famous "Preface" in which he defined poetry as "the spontaneous overflow of powerful feelings: it takes its origin from emotion recollected in tranquillity" and argued that poetry should be written in "the real language of men."

Wordsworth's poetry was roundly condemned by the critics for its "low" subject matter and language. Francis Jeffrey, a highly influential critic writing in the *Edinburgh Review*, severely attacked Wordsworth's radical poetic departure and, in response to the 1814 publication of *The Excursion*, issued his famous dismissal, "This will never do." Wordsworth's poetry was also the target of satire. In 1808 *The Simpliciad: A Satirico-didactic Poem* offered "Hints for the Scholars of the New School." *The British Critic* referred to *The Simpliciad* and pronounced this judgment on *Poems, in Two Volumes*: "such flimsy, puerile thoughts, expressed in such feeble and halting verse, we have seldom seen." Wordsworth's task was difficult indeed for he had to create the audience for his poetry of, in the words of the preeminent Wordsworth biographer, Stephen Gill, "the familiar, the homely, and the unregarded."

Intimacy, Sorrow, and Creative Work

Close associations and intimate friendships were important throughout Wordsworth's life although he expressed reticence in making new acquaintances. The early deaths of their parents influenced the close bonds between Wordsworth and his four siblings. Upon their mother's death Dorothy was sent to live with her mother's cousin, Elizabeth Threlkeld, and she did not see her brother William again for 9 years.

When they were reunited in young adulthood, William and Dorothy Wordsworth shared a brother-sister intimacy of unique complexity and passionate devotion. He called her "My hope, my joy, my sister, and my friend,/Or something dearer still, if reason knows/a dearer thought, or in the heart of love/There be a dearer name." She refers to him in her journal as "my Beloved" and "my darling." Wordsworth grounded his being and his creative work in the loving domestic community that he and Dorothy, and later Mary Hutchinson, his wife, established. In addition to the emotional support offered by his circle, Wordsworth also found a group of ready helpmates to transcribe his poetry and offer useful criticism. Of fundamental importance to his creative work was their belief in his calling as a poet.

Wordsworth's friendship with the poet Coleridge was among the most important relationships of his life and was central to the development of both poets' creativity. Coleridge described the bond that he felt with William and Dorothy Wordsworth in 1798 as "three persons and one soul." In 1810 Wordsworth became estranged from Coleridge, and although there was a reconciliation of sorts, their intimacy never regained its previous intensity or level of trust. Coleridge thereafter referred to the break in the friendship as one of the greatest sorrows of his life.

Though Wordsworth was blessed with a devoted circle of friends and family, his adult life was not without pain and loss. His brother John's death in 1805 in a shipwreck came as a serious blow. Almost 40 years later Wordsworth's grief over the loss of his brother was still powerfully evident in the 1842 volume, *Elegiac Verses: In Memory of My Brother, John Wordsworth*. In a period of 6 months in 1812, two of Wordsworth's children died: Catherine, aged 3 years, and Thomas, aged 6 years. Wordsworth grieved the loss of his children intensely, expressing his feelings about Catherine, whom he called his "heart's best treasure," in the sonnet, "Surprised by Joy." In the 1812 revisions of *The Excursion*, Wordsworth drew on his own losses to incorporate themes of pain, disillusion, and fear into the character of the Solitary.

Following the deaths of the two children, the Wordsworth household moved to Rydal Mount and rebuilt their domestic security. In the last 20 years of Wordsworth's life, however, the haven of personal stability that had been so important for his productivity was shaken to its roots. Beginning in 1829 his sister Dorothy suffered a series of physical and mental breakdowns, requiring long periods of bed rest and nursing. She developed a dependency on opium and displayed senile dementia resembling Alzheimer's disease. She was nursed at home during her quarter-century decline, which dramatically altered the normal social life of the household that had been so precious to them all.

Dorothy outlived Wordsworth, dying in 1855. Ironically, at the time that public acclaim for his poetry was increasing, the

people who had supported his creative work, and served as the sources of his personal stability and strength, began to die. In the last years of his life, Wordsworth was deeply affected by the series of deaths of family members and friends, including the deaths of Mary Wordsworth's sisters, Sara Hutchinson (1835) and Joanna Hutchinson (1843); Edward Wordsworth, a 5-year-old grandson (1845); Christopher Wordsworth, his brother (1846); John Wordsworth, his nephew (1846); Dora Wordsworth Quillinan, Wordsworth's beloved daughter who had married against his wishes (1847); and Hartley Coleridge (1849) to whom he demonstrated a lifelong fatherly protection.

Fiscal Survival in the Life of the Poet

Wordsworth struggled to survive financially through much of his life. When their father died, the Wordsworth children had been unable to collect a sizable claim for funds that their father had spent conducting the affairs of his employer, Lord James Lonsdale. Eighteen years of economic dependency on rather unsympathetic relatives elapsed before the claim was settled at the death of Lord Lonsdale.

Modest economic help came to Wordsworth early in his career through an inheritance from Raisley Calvert, whom Wordsworth had nursed until he died from tuberculosis. In *The Prelude* Wordsworth recognized Calvert, along with Dorothy and Coleridge, as having enabled him to realize his destiny as a poet. His financial position finally changed in 1813 when he acquired the position of distributor of stamps, leading Browning to lament, "Just for a handful of silver he left us." He held that position until 1842 when he was given a civil list pension.

Wordsworth's Accomplishments

The Organization of Poetic Purpose

The creativity theorist Gruber has suggested that each creative person has particular conceptions of his or her life tasks. This network of enterprise constitutes the person's organization of purpose, defines the working self, and provides a structure that organizes a complex life. Wordsworth had a highly individualized sense of vocation as a poet that he described in *The Prelude*. In the context of his intimate friendships, especially that with Coleridge, he elaborated a plan that occupied his creative efforts for decades. One of the difficulties of his creative life was that his friend Coleridge had aspirations for Wordsworth to be a philosophical poet when his true gifts and vision lay elsewhere. Plans for *The Recluse* were not abandoned until 1838, several years after Coleridge's death. Another difficulty of his poetic career was that for a considerable part of it he did not seek to publish his major poems, which were being revised in manuscript. Hence he faced the dilemma of privately feeling a strong sense of poetic vocation without an accompanying public recognition of that identity. He had started writing verses as early as 1786 about his "thoughts and images" of the Lake District scenery in which he was raised. While a freshman at Cambridge University he composed a large part of the *An Evening Walk*, completing it in 1789. In 1790 he took a walking tour with his Cambridge friend Robert Jones in France and Switzerland, which is celebrated in *Descriptive Sketches*. In January 1791 Wordsworth

took his B.A. degree and went to France, ostensibly to spend a year learning French. During his sojourn in France he wrote much of *Descriptive Sketches*, which was published with *An Evening Walk* in February, 1793, the same month in which England declared war on France.

Wordsworth experienced a deep sense of alienation from his own country and was at a loss to plan his personal future during this period. Complicating his personal outlook was his inability to return to France where Annette Vallon had given birth to his child. In the autumn of 1793, he began work on *Guilt and Sorrow*, his first considerable poetic project. Finished in 1794, a part of it, under the title of *The Female Vagrant*, was printed in the *Lyrical Ballads* in 1798. A revised form was published in 1842. He was occupied with *The Borderers: A Tragedy* in 1795 and 1796. In 1795 he and his sister Dorothy settled at Racedown where Wordsworth began *Margaret, or The Ruined Cottage*, finishing the work at Alfoxden where the Wordsworths moved in 1797 to be near Coleridge at Nether Stowey. In *The Prelude* Wordsworth describes the healing influence of his sister and Coleridge during this period. Following the September, 1798, publication of the *Lyrical Ballads*, in one of the coldest winters of the 18th century, the Wordsworths spent several lonely months in a provincial town in Germany where he began writing what would later become his great autobiographical poem, *The Prelude*. Far from his beloved English Lake District, he deeply examined the memories of his childhood and took the first tentative steps in a major literary enterprise that would occupy him at intervals for close to 40 years.

In October 1799 he settled in Grasmere and was a permanent resident of the region for the rest of his life, leaving only for an occasional trip to Scotland, London, or the Continent. In 1800 he added a preface to the second edition of *Lyrical Ballads*, and a second volume of poems, including some of his finest works. A third and fourth edition appeared respectively in 1802 and 1805. In 1804 he married his childhood friend Mary Hutchinson. In 1807 he published the *Poems in Two Volumes*, including the "Ode to Duty" and the "Ode on Intimations of Immortality." These volumes established Wordsworth as a great innovator of poetic form. Indeed, by 1807 arguably much of his greatest work had been completed, including the volumes of 1800 and 1807, *The Prelude*, the *Recluse* fragment, and *Margaret, or the Ruined Cottage*.

An account of Wordsworth's oeuvre is complicated by his habits of revision, often extending over decades, and his rearranging poems for publication. *The Excursion* was published in 1814, followed in 1815 by the first collected edition of his works and *The White Doe of Rylstone*. Five years elapsed before the series of his later works began to be published, including *The River Duddon* and *Miscellaneous Poems* (1820), *Ecclesiastical Sketches* (1822), and *Evening Voluntaries* (1835).

The Poet Writing Prose

Although Wordsworth is remembered primarily as a poet concerned with the human relationship to nature, he also wrote at least two prose works of continuing general interest, "Preface to *Lyrical Ballads*," his statement of poetics, and "A Guide through the District of the Lakes," his tourist handbook to the landscape of his native region. His political writings

include "A Letter to the Bishop of Llandaff," written in 1793 but not published until 1876, *The Convention of Cintra* (1809), and *Two Addresses to the Freeholders of Westmoreland* (1818). Although *The Convention of Cintra* has been criticized as a reactionary nationalistic rejection of Wordsworth's youthful embrace of revolutionary radicalism, the essay is grounded in Wordsworth's view of the potential of human nature and the human heart. Statesmen, he asserted, living in their isolation and artificial world, lack vital knowledge, "a knowledge of human kind." Although Wordsworth's essay had no significant impact on subsequent political decision making or public opinion, and 178 of the 500 copies printed were sold as waste paper, writing the essay provided focus for ideas to be expressed in *The Ruined Cottage*, later a part of *The Excursion*.

Constructive Repetition and Revision

Constructive repetition is a fundamental process in creative work. As Bernstein wrote in *The Unanswered Question*, "the repetitive principle is at the very source of musical art (and of poetry)." Repeated contact with ideas, images, or sounds may enable a creator to discover new meanings and to reorganize and modify previously formulated views or expressions. Revision may be understood in this sense to be one form of constructive repetition. Writers may differ as to the value that they place on revision in their work process. For many creators, the patience, discipline, and willingness to put time and energy into reworking a creative product are crucial for the accomplishment of their creative goals. By the same token, compulsive revision may become counterproductive in creative work.

Wordsworth was internally driven to revise. Gill has suggested that Wordsworth found the idea of finality unbearable. For Wordsworth to republish a poem without first subjecting it to revision was to him unthinkable. Moreover, multiple fair copies had to be produced as Wordsworth continued to cross out, substitute words and phrases, and interline even as the printing process commenced. One marvels at the patience of Dorothy, Mary, and his daughter Dora who frequently served as his transcribers. Even his son-in-law, Edward Quillinan, was enlisted on occasion as scribe and recorded in his diary his disappointment that "helping Mr. W. to tinker" prevented his partridge shooting. In addition, intense revision put Wordsworth out of sorts and made him irritable and unwell. In an 1840 letter from Salzburg to his wife, he apologized to his "inestimable fellow-labourer" for his irritable state caused by "overstrained labor."

Revision and Elaboration: Microanalysis

Composing is a process that requires, as Vera John-Steiner in *Notebooks of the Mind* has suggested, an ability to synthesize germinal ideas with elaborative structures. The record of Wordsworth's worksheets reflects a work process in which constant revision takes place as the poem is created.

The earliest drafts for *The Prelude* may serve as an example of this process. Unpublished during the poet's life, *The Prelude* took the form of three major versions. The 1799 *Prelude* is the

first version. Twenty-four pages of drafts toward Part I of the 1799 *Prelude* are found in a notebook, MS JJ, dating from Wordsworth's trip to Germany. A rich source of information concerning the process of poetic creativity, these drafts are the record of the birth process of a poetic masterpiece.

The 24 pages of drafts contain approximately 420 lines. Only about 26 lines were not later used in the 1799 *Prelude*, for a later version of *The Prelude*, or for some other poem. Wordsworth displayed a frugality with his poetic creation, and apparently found it difficult to discard lines. About 140 lines of Part I first appear in MS JJ, and are included unchanged in the 1799 version. The Gestalt of Part I of the 1799 *Prelude* emerged in the MS JJ worksheets. Lines composed early in the MS JJ drafts serve as the opening of 1799 *Prelude*, and lines composed toward the end of the drafts became the conclusion of Part I. There are over a hundred revisions in these 24 pages of drafting, mostly instances in which Wordsworth substituted a word, phrase, or line for another. Rarely did he delete material without replacing it. The 24 pages each vary markedly in the number of revisions that they contain, ranging from 12 to none with an average of about four revisions per page. The number of revisions per page declined as composition proceeded, reflecting an interaction between the poet and his poem. The growing structure of the poem both guided his composition and limited his alternatives.

The MS JJ drafts had been completed in Goslar, Germany, during the winter of 1798–1799. After these drafts were written, the Wordsworths left Goslar, travelling for a period in Germany before returning to England in early May. At Sockburn, the home of Mary Hutchinson who would later marry Wordsworth, Wordsworth began writing again. By the end of 1799, approximately a year after the first MS JJ drafts were composed, Wordsworth completed the two-part *Prelude*. Gill has offered an account of revisions in other Wordsworth poems, including most of the poems in later editions of the *Lyrical Ballads* and *The Female Vagrant*. Wordsworth changed single words, phrases, and occasionally wrote lines as well as moving stanzas around. He also changed the titles of poems on occasion. Characteristic of Wordsworth's style of revision was a blindness to scale of revision, treating all revision as important.

Poems as Living Presences

Writing poetry is a way of thinking. The thinker as poet may revise a previously written poem as his or her thinking changes about an idea or image or experience. In the process of writing, a dialogue between the thinker and his or her written words, as Bruner has described it, may develop. Wordsworth had this kind of relationship, in a sense, a conversation, with his poetic creations. He treated his poems, as Gill has pointed out, not as discrete objects, but rather as "living presences" of a mind that registered its evolution not only in the creation of new work but in the transformation of old work. Although the subtitle of *The Prelude* was "Growth of a Poet's Mind," the true record of the development of Wordsworth's mind is in the revisions that he made in his poems throughout his long life.

The Final Years

In 1843 Wordsworth succeeded Southey as poet laureate at a time in his life when he had, ironically, for the most part stopped writing poetry. In the early 1840s he became an increasingly pious man, identifying himself as a Christian poet, and revising *The Excursion* of 1845 to be an explicitly Christian poem. Preparation of the 1845 volume constituted Wordsworth's last major poetical effort.

To a degree troublesome to Mary Wordsworth who complained of the American visitors, Rydal Mount became a shrine for those seeking the venerable sage, and the tourists came in droves. He continued his lifelong habit of walking, even crossing the Malvern Hill twice in the last year of his life. In his final illness, pleurisy, he was bedridden for a month. In pain and with trouble breathing, he suffered at the last until he died at noon on April 23, 1850.

Wilbur Wright 1867–1912 and Orville Wright 1871–1948

Inventors

Inventors of the first successful powered airplane

WILBUR AND ORVILLE WRIGHT placed their names firmly in the pantheon of great American inventors with their creation of the world's first successful, powered, heavier-than-air flying machine. The airplane they designed and built in Dayton, Ohio, and flew at Kitty Hawk, North Carolina, on December 17, 1903, inaugurated the aerial age, one of the defining characteristics of 20th century. The Wrights began serious experimentation in aeronautics in 1899 and perfected their craft by 1905. In this short period, with remarkable originality, they defined the essential elements of the problem, conceived creative technical solutions, and built practical mechanical design tools and components that resulted in a viable aircraft. They did much more than simply coax a machine off the ground. They established the fundamental principles of aircraft design that are still in place today. In 1908, they demonstrated their invention publicly in the United States and Europe and became instant international celebrities. By 1910 the Wright Company was manufacturing airplanes for sale and the brothers were on their way to becoming wealthy men. Despite the Wrights' dramatic leap ahead of the rest of the aeronautical community, contemporary experimenters and would-be aviators quickly caught up to the brothers and surpassed their designs. Nevertheless, it was Wilbur and Orville Wright who made the pivotal breakthrough after countless others had failed, and they did so virtually alone. Transport by air of material and people, quickly over great distances, and the military applications of flight technology have had an incalculable economic, geopolitical, and cultural impact all over the globe. The Wright brothers' invention not only solved a longstudied technical problem, but it helped create a new world.

Background

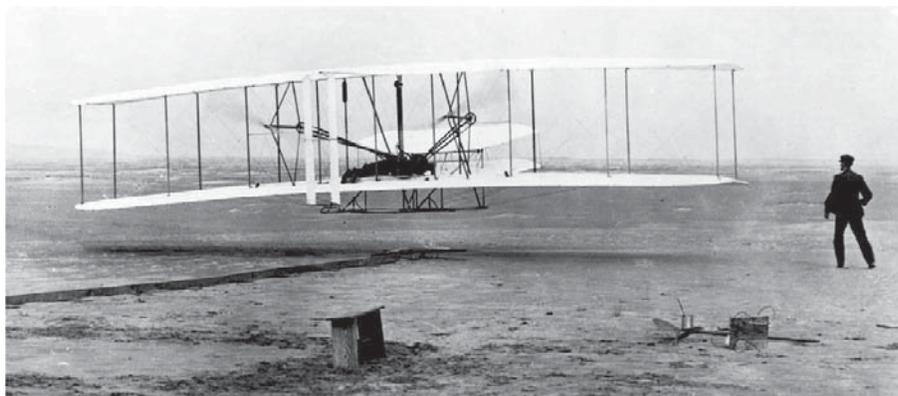

The Wright brothers were the product of deep midwestern American roots. Several generations on both sides of the family

had been early settlers on the Ohio and Indiana frontier. Their father, Milton Wright, was an itinerant minister, a bishop in the Church of the United Brethren in Christ. His calling would take the family to numerous church posts throughout the region.

Milton's wife, Susan, already a member of the United Brethren when they met, was a bright, shy, capable woman. She had studied literature at Hartsville College, though she left 3 months short of graduation. She also possessed considerable mechanical aptitude, a trait passed on to her sons. After a long courtship and lengthy separations due to Milton's missionary travels, he and Susan were married in 1859 to begin a Christian life devoted to the Church. Wilbur and Orville were two of five surviving children borne by Susan Wright. Two older brothers, Reuchlin and Lorin, arrived in 1861 and 1862. Wilbur was next, born on April 16, 1867, near Millville, Indiana. After giving birth to a set of twins that died in infancy, Susan delivered another healthy son, Orville, on August 19, 1871, in Dayton, Ohio. The Wrights' last child, a daughter named Katherine, was born three years to the day after Orville, in 1874.

Despite their frontier heritage, Wilbur and Orville lived and worked in the suburban, middle-class neighborhood of West Dayton, Ohio. They grew up during the early industrialization of America, and by the time they began their aeronautical experiments in the 1890s, they had witnessed the emergence of numerous technologies that would define the modern era. Milton and Susan were stern disciplinarians but warm, loving parents.

They encouraged the intellectual curiosity and creative pursuits of all their children. Although neither Wilbur nor Orville received a high school diploma, both were committed to broad learning and were excellent students. They made good use of the rich family library and supplemented their formal

The "moment" of invention. On December 17, 1903, at 10:35 a.m., the Wright *Flyer* lifts off the beach at Kitty Hawk, North Carolina, with Orville Wright at the controls. Wilbur Wright, at right, observes the brothers' triumph. Courtesy of the Library of Congress.

schooling with a great deal of private study. Though technically high school dropouts, such a characterization belies their extensive self-education and strong intellect.

By 1890 Reuchlin and Lorin had moved out and started families of their own, and Susan Wright had succumbed to tuberculosis. The remaining four Wright family members became an extremely close-knit group, all continuing to live in the same household, providing a network of support that carried them through all manner of crises and triumphs. Despite their powerful commitment to family, Wilbur and Orville remained lifelong bachelors and had no children of their own.

As teenagers the Wright brothers showed little direction or focus toward their future. Wilbur's early plans to attend Yale Divinity College were thwarted by a series of health problems and a funk he fell into following the death of his mother. Orville flitted about from one interest to another. The printing trade was an early pursuit that seemed to hold some sustained interest for the younger Wright, and ultimately Wilbur joined him in several small printing business ventures. But it was in 1892, when the brothers opened their first bicycle rental and repair shop, that Wilbur and Orville found a livelihood to support themselves. At ages 25 and 21, they had settled into the comparatively ordinary life of hardworking local businessmen. It was also during this time that the close relationship and teamwork that would be so important to their aeronautical work solidified.

Creative Methodology

The Wright brothers' story always begs the basic question: How did these two modest, seemingly unremarkable bicycle shopkeepers develop such a world-changing invention as the airplane? How were these men, working essentially alone with little formal scientific or technical training, able to solve a problem so complex and demanding as heavier-than-air flight in only a few short years when it had defied better-known experimenters for centuries? In short, why Wilbur and Orville?

On the surface, the fact that the Wrights did invent a successful airplane quickly and with little assistance would suggest that sheer genius had to have been at the core of their achievement. Probing deeper, however, it becomes apparent that there were a number of specific research techniques, innate conceptual skills, and personality traits that came together in a unique way to largely explain why these two men invented the airplane.

In short, Wilbur and Orville had a definable inventive method that in very direct terms led them to the secrets of flight. The Wright brothers unquestionably were talented people. They do indeed deserve much of their towering reputation as inventors. But their genius should be understood in terms of the approach they evolved and employed to create the technology of flight, not just the singular act of getting a machine into the air. Examining the Wrights' inventive methodology peels away some of the mystery behind their rapid and startling success and adds even more luster to their accomplishment.

First and foremost, the Wright brothers' approach to mechanical flight was grounded in strict engineering techniques. They did not develop their aircraft using uninformed trial-and-error methods like so many of their contemporaries.

Nor did they tackle the problem as scientists. Wilbur and Orville did not set out to discover the theoretical principles of flight in the same sense that Newton or Einstein sought to explain physical phenomenon in nature. The Wrights' work focused explicitly on determining the design features required to make an airplane fly. Indeed, they not only invented the airplane, but they invented aeronautical engineering in the process.

Merged with this basic engineering perspective and its associated practices were a number of conceptual capabilities and approaches present in the Wrights' method that in large measure explain their inventive success. Among the most important was their capacity for developing conceptual models of a problem that could then be transformed into practical hardware. The brothers' considerable ability for turning abstract concepts into workable machinery reveals itself over and over again in their aeronautical work.

Another prominent feature of the Wright brothers' creative thought process was the great extent to which they used mental graphic imagery and nonverbal thought to conceptualize basic structures and mechanisms, even aerodynamic theory. There is invariably a distinct facet of design that is aesthetic in nature, an aspect that results from the maker's particular sense of what will or will not work or what looks right or wrong. Frequently, truly ground-breaking technological innovations are not based solely on articulated scientific or engineering principles, mathematical calculations, or other forms of knowledge that can be expressed verbally. The designer literally has a vision of what the object or structure should look like and how it will work and, in conjunction with verbal forms of knowledge, produces a tangible article based on these nonverbal ideas. Wilbur and Orville's keen facility for nonverbal thought was among the most prevalent and salient aspects of their inventive method. The Wrights reinforced these innate talents with several sound approaches to technological innovation.

They developed a series of gliders and powered airplanes that were based on a single, evolving basic design, modifying only a few factors at a time. This continuity of design allowed them to isolate flaws and capitalize on design successes, and thereby move ahead rapidly. Though seemingly an obvious approach, many of the Wrights' contemporaries jumped from one radical design to another.

Wilbur and Orville also understood that an airplane was not just one invention but numerous inventions all working in concert to produce a workable flying machine. The airplane is a technological system, each component of which, including the pilot, had to be addressed.

The Wrights saw no individual component to be more important than any other. Aerodynamics could not be focused on at the expense of structure, propulsion at the expense of control, and so on. The Wrights' unwavering attention to the complete technological system of mechanical flight was crucial to their success. Technological transfer, drawing concepts and even hardware from seemingly unrelated fields, also played a valuable role in the Wrights' creativity. The most conspicuous example was the bicycle. In addition to utilizing a number of mechanical devices from bicycles, such as sprockets and chain drives, the vehicle was the source of an important conceptual idea regarding flight control. The bicycle is an utterly unstable

machine but completely controllable. Intimate familiarity and comfort with this characteristic in bicycles freed the Wrights to think of airplanes in the same way. The Wrights were not bound by the idea that airplanes must be inherently stable, as were so many other aeronautical experimenters of the day. This concept was critical to the development of the brothers' effective control system, a key element of their invention.

No less important to understanding the Wright brothers' creative achievement was their personal relationship and outlook. More than simply a closeness between brothers, they possessed a synergy, sometimes forged through heated yet constructive argument, that produced collaborative solutions to vexing technical problems. Moreover, their closeness with the other members of the family, often serving as protection from what they perceived as a pernicious, untrustworthy outside world, provided a supportive environment.

This instilled confidence to reject the theories of well-known and experienced aeronautical researchers when the brothers felt their own ideas were correct. Finally, when seeking to explain the Wright brothers' inventive success, the factor of timing cannot be ignored. They took up the problem of heavier-than-air flight at a propitious moment. By the time the Wrights entered the field, the study of aeronautics had been legitimized by several prominent late-19th century experimenters, and a foundation of aeronautical knowledge was coalescing around their work. Although the Wrights worked alone, they did not operate in isolation of the advancements contributed by their predecessors. Despite the high degree of originality in their work, there is no reason to believe that the Wright brothers would have invented the airplane no matter when they took up the problem.

The creation of any fundamentally new technology is the result of a myriad of unique factors. The airplane is no exception. The elements cited here, however, were central to the Wright brothers' inventive success. This particular combination of engineering techniques and approaches, innate conceptual abilities, and personality traits and circumstances go far toward answering the basic question: Why Wilbur and Orville?

Invention

The Wright brothers did not possess a lifelong passion for flight when they began their investigations in the late 1890s. Wilbur in particular was casting about for something to quell his restless intellect. The bicycle business furnished an adequate living, but it did not offer the mental rigor the brothers' active minds craved. The airplane quickly became a consuming passion, but at first it was only an outlet for the Wrights' inquisitiveness.

They began with a literature search to acquaint themselves with the work of their predecessors. A letter to the Smithsonian Institution in 1899 was among their initial inquiries. After absorbing the information the Wrights received from the Smithsonian and other sources, they quickly recognized that control of the aircraft was a fundamental problem to be solved, and to their surprise, few experimenters had theretofore given it much thought.

In the fall of 1899 the brothers developed a basic means of lateral control and tested the mechanism with a small 5-ft

wingspan biplane kite. The idea would prove to be among their most significant and creative innovations. It would in fact be the central element of their later 1906 patent on the airplane. The idea was also one of the more striking illustrations of their creative skills and method.

Of the Wright predecessors who concerned themselves with control at all, some balanced their craft by continually altering the center of gravity of their aircraft by shifting the body weight of the pilot. Others simply tried steering with a rudder similar to how a ship maneuvers in water. Recognizing that the first approach was limited and that the second was technically flawed, the Wrights chose to control their aircraft aerodynamically. They reasoned that if a wing generates lift when presented to an oncoming flow of air, producing differing amounts of lift on either end of the wing would cause one side to rise more than the other. In other words, it would cause the wing to bank. If the pilot could mechanically alter the amounts of lift on either side of the aircraft when and to the degree the pilot chose, the aircraft could be maintained in level flight in the face of wind gusts or other forces and could be turned when desired.

The Wrights achieved this control by a means they termed *wing warping*. To induce the differing amounts of lift on either side of the airplane, the brothers literally twisted, or warped, the wing structure such that one side was presented to the wind at a higher angle than the other, which increased the lift on that side, thereby setting up the bank of the whole craft. Lines were attached to the ends of the wings and manipulated by the pilot via a hip cradle mounted at the center of the wing to induce the warp. The idea was seminal because it contributed to a method of effectively controlling an aircraft in three-dimensional space, and since it was aerodynamically based, it did not limit the size of the aircraft as body weight shifting obviously did. All aircraft continue to use this basic means of lateral control developed by the Wright brothers.

This aspect of the Wrights' work was not only at the heart of their invention, but it is a telling illustration of their creative methodology and thought processes. They adeptly moved from the abstract idea of aerodynamic control to a concrete structural and mechanical means of employing the concept. Wilbur hit upon the idea of warping the wings after serendipitously twisting a bicycle inner tube box in his fingers one day. He noticed that the box could be twisted longitudinally and still maintain its structural form. The Wrights' biplane wing arrangement mirrored the structural cell of the box. This is a powerful example of visual thinking at work in the design process. Further, even though they worked this idea out on small kites and gliders, they kept the goal of a practical airplane in mind and knew they had to conceive something that could be used in a larger, powered vehicle later. All these aspects of the Wrights' development of the critical wing warping system demonstrate their creative talents at their finest.

Encouraged by the success of their small wing warping kite, the brothers went on to build and fly two fullsize, piloted gliders in 1900 and 1901, testing them on the isolated sand dunes at Kitty Hawk, North Carolina. Although the control system worked well and the structural design of the craft proved sound, the Wrights continued to experience aerodynamic problems with these designs. The gliders simply did not produce the amount of overall lift that their

calculations predicted they should. Now at a critical juncture, Wilbur and Orville decided to conduct an extensive series of aerodynamic tests of their wing shapes. They built a small wind tunnel in the fall of 1901 to gather a body of accurate aerodynamic data on which to design their next glider.

The heart of the Wright wind tunnel was the test instruments mounted inside to measure coefficients of lift and drag, the terms in the equations for calculating lift and drag about which the brothers were in doubt. Like the wing warping system, these wind tunnel instruments are striking examples of the Wrights' ingenuity and skill. They were in essence mechanical analogues of the mathematical aerodynamic equations the brothers were using to design their aircraft. They were physically constructed such that all the factors other than the one they wished to investigate dropped out of the readings taken from the instruments. The resulting data could then be used directly to determine the shape and to calculate the size of wings. The ease with which the Wrights incorporated an abstract mathematical relationship into a practical piece of hardware that yielded concrete design information goes to the heart of their creative capabilities and approach and their inventive success.

The Wrights' third glider, built in 1902 based on the wind tunnel experiments, was a dramatic success. The lift problems were solved, and with a few more refinements to the control system they were now able to make numerous extended glides. An important element could easily be overlooked—not only had the brothers built a viable flying machine, but they were now able to gain valuable practice in the air; they could teach themselves to fly. This skill would be vital when attempting to fly a heavier, more complex powered airplane later. The Wrights understood that the pilot was yet another component of the overall system that had to work properly to achieve mechanical flight.

Buoyed by the success of their 1902 glider, the Wrights were now convinced they stood at the doorstep of realizing the age-old dream of human flight. During the spring and summer of 1903 they built their first powered airplane. Maintaining the basic continuity of their proven glider design, the only fundamentally new element of the 1903 craft was the application of power. The brothers made a small, 12-horsepower gasoline engine, which was no insignificant achievement. But the truly innovative aspect of the propulsion system was the propellers.

After realizing that marine propeller theory was nearly non-existent and inapplicable to flight, the Wrights designed an aerial propeller that stands out as one of the most creative

aspects of their entire airplane. They reasoned that if a wing moving horizontally in a flow of air produces a vertical lift force, a similar airfoil-shaped structure turned on its side and spun to create the flow of air over the surface would produce horizontal thrust; in essence, they envisioned a rotary wing.

The details of actually designing the propeller proved to be quite complex, but this basic concept was sound and revolutionary. All aircraft propellers since have been of the Wright design. Again, it is apparent that Wilbur and Orville's facility to see abstract principles in physical structures and materials, and their mental agility at manipulating these visual forms in their mind's eye, enabled them to create a critical component of the airplane.

By the fall of 1903, with the powered airplane ready for trial, the brothers headed south to their flight test site of Kitty Hawk. Once they had resolved some teething problems with the engine transmission system, the Wrights were ready. After four years of intensive effort, Orville lifted the Wright *Flyer* off the beach at 10:35 a.m., on December 17, for a 12-s flight. They made three more flights that morning, alternating pilots. With Wilbur at the controls, the fourth and last flight covered 852 ft in 59 s. With this long, sustained flight, there was no question the brothers had flown. The aerial age was born.

At the conclusion of this flight, a gust of wind picked up the *Flyer* and cartwheeled it across the beach. Badly damaged, the world's first airplane was never flown again. After bringing their design to practicality with two more powered machines in 1904 and 1905, the Wrights stopped flying entirely for 2½ years to secure their patent, which was granted in 1906, and to try and sell their invention. In the summer of 1908, they demonstrated their creation in the United States and Europe, amazing crowds of observers on every occasion. They were no longer Wilbur and Orville Wright, proprietors of the Wright Cycle Company. They were now the Wright brothers, inventors of the airplane.

Glossary

Alcoholism Dependence on alcohol that results in increased physical, psychological, occupational, and financial problems that may result in death.

Depression A psychoneurotic or psychotic disorder marked especially by sadness, inactivity, difficulty in thinking and concentration, a significant increase or decrease in appetite and time spent sleeping, feelings of dejection and hopelessness, and sometimes suicidal tendencies.

DSM The diagnostic and statistical manual issued by the American Psychiatric Association.

Hypomania A mild mania, especially when part of a manic-depressive cycle.

Manic-depression Characterized either by mania or by depression, or by alternating mania and depression.

Schizoaffective disorder A class of mental disorder characterized by symptoms of schizophrenia and by disturbances in mood that are similar to those in the affective disorders.

Schizophrenia A psychotic disorder characterized by loss of contact with the environment, by noticeable deterioration in the level of functioning in everyday life, and by disintegration of personality expressed as disorder of feeling, thought (as in hallucinations and delusions), and conduct – called also dementia praecox.

Schizotypal personality disorder A mental disorder less severe than schizophrenia characterized by more mild disturbances in cognition and affect.

Techniques

Studies of Biographies

Researchers seek generalizations about eminent writers by compiling statistical data using biographies. They compare this data with information about other creative achievers and the general population, looking for any significant differences. Conclusions from these types of studies may apply to writers as a group, but do not indicate the characteristics of any individual writer.

Interviews and Assessments of Writers

Researchers interview eminent writers about their work and in some cases give them psychological evaluations and tests. The majority of these studies evaluate the characteristics and mental health of writers. Other researchers conduct semi-structured interviews focusing on a writer's background, career path, motivation, work habits, internal processes, and personal life. When multiple interviews are conducted, connections that indicate similarities and differences between the subjects are usually offered. Researchers have also used archival interviews in books, magazines, and newspapers to analyze prominent writers.

Case Studies

Researchers prepare case studies about individual writers by studying their life and work. The results presented in this entry will not emphasize individual case studies since they are usually complex and vary widely depending on the training, methodology, and perspective of the author. Study of collaborative creative writing is just beginning. A combination of interviewing, observation, and evaluation of changes in the work offer

insights into the decision-making process as well as the personal dynamics and leadership factors which may encourage or discourage creativity. Case studies may provide valuable insights but the results can not be generalized.

The psychobiography

Freud expressed admiration for creative writers who he said were far in advance of everyday people, because they draw on sources which have not yet opened in science. Freud wrote about the life of DaVinci which served as the prototype for the psychobiography, a format in which key psychological elements in an author's life, which theoretically influenced their work, are presented. Psychobiographies are almost always made without the subject's participation. Critics of this methodology complain there is a great deal of unproven speculation involved, as analyses are not based on experiments or independent evidence. The psychoanalytic method may reduce life to psychological processes, ignoring social, economic, or political forces. More recent researchers in creativity, such as Howard Gardner, concluded that Freud's characterizations apply to noncreative as well as creative individuals and thus do not distinguish the effective artist or scientist from the banal one. Others believe that though Freud's work was not scientifically accurate, his method might provide an imaginative look into the mystery of creativity.

The literature includes many articles by psychological practitioners who analyze the content of a writer's work including themes and specific characters in relation to a specific personal characteristic of the author, such as psychopathology, addiction, disease, or wish fulfilment. A few psychoanalysts and psychologists, most notably Albert Rothenberg, worked with writer-clients who allowed them to write about their creative process using aspects of their therapy.

The systems approach

The evolving systems approach examines the creative person's life in five contexts, including: total body of work, the milieu in which they worked, their family and personal life, and the sociohistorical period in which they lived. This approach has been used in studying writers by examining their creative process based on different drafts of their work and their own recollections.

Results of the Research

Early Family History

Large scale biographical studies consistently indicate that successful writers came from more turbulent family backgrounds and suffered more emotional instability when they were children. Mildred Goertzel, Victor Goertzel, and Ted Goertzel studied the lives of 717 eminent personalities who had two or more biographies written about them since 1962. The Goertzels compared 92 literary figures with other eminent personalities who lived in the twentieth century. They found writers were:

1. More likely to be only children (26% vs. 17% overall).
2. Tended to be voracious readers (77% vs. 48%).
3. Disliked school (52% vs. 33%).
4. Came from homes described as very unhappy (67% vs. 44%).
5. Had more alcoholic parents (one or both) (11% vs. 7%).

Jane Piirto reviewed the lives of 160 writers using survey questionnaires, essays, published interviews, and reference books. She found family trauma was a theme including alcoholism, parental suicide, weak or absent fathers, being orphaned, poverty, physical and sexual abuse, divorce, and mental illness. A few writers had placid childhoods but they represented a small percentage. Numerous writers and researchers have commented that writers may often find a way in their work to create a new world for themselves.

Arnold Ludwig examined the lives of 1004 eminent people who had a biography reviewed in *The New York Times Book Review* between 1960 and 1990. Included in the total were 180 fiction writers, 64 nonfiction writers, and 53 poets. He found that writers were more likely to have fathers, mothers, and siblings with identifiable pathological problems. In a separate study, Ludwig found that significantly more women writers came from families with mothers or fathers with psychopathology and that more of these writers were physically or sexually abused as children.

Kay Jamison made a long list of writers who had close bipolar relatives which included Robert Burns, Charles Dickens, Ralph Waldo Emerson, Henry James, William Faulkner, and F. Scott Fitzgerald. This may have be a creative advantage since research conducted by Ruth Richards and Dennis Kinney indicated that an individual who has a close relative with manic-depression is more likely to be creative.

Education

Not surprisingly, the majority of children who became writers were voracious readers who escaped into the world of books and in some cases movies. Freud wrote about the relationship

between childhood fantasy and writing: "Might we not say that every child at play behaves like a creative writer, in that he creates a world of his own, or, rather, rearranges the things of his world in a new way which pleases him?" (1908: 131-132).

Exceptional curiosity was a common trait along with an early interest in writing. Young writers such as Eugene Ionesco, Sylvia Plath, and Pearl Buck displayed promise and received encouragement from teachers for their writing skills. However others such as Academy Award winning screenwriters William Goldman and Tom Schulman did not display any particular talent for writing until later in life. Many creative writers were bored or just felt they did not fit in. High school dropouts include famous writers such as Herman Melville, Mark Twain, Ring Lardner, Will Rogers, and Noel Coward.

However the romantic notion of the dropout writer who lives in poverty until discovered is changing as the path for many successful writers, especially novelists, includes an undergraduate and graduate school degree, often from top-flight schools that may allow them to teach as their writing career evolves. Programs such as the Iowa Writers Workshop and UC Irvine and top film schools such as USC and UCLA are training successful writers.

Mental Illness

Writers, along with other creative artists, have been subject to the speculation that genius and madness are linked. This association has been traced back to Plato's colorful description of poets' 'divine madness' as well as Aristotle's claim that all creative people were touched with melancholia. Biographical studies support the notion that fiction writers and poets had much higher rates of psychopathology than other creative professions and the general population.

For example, Arnold Ludwig reported that 28% of his total sample of writers had a mental disorder in their lifetime including a striking 87% of poets, 77% of fiction writers, and 72% of nonfiction writers. Women writers may be even more at risk. Ludwig interviewed and compared 59 female writers matched with a control group. He found female writers had higher rates of depression (59% vs. 9%), alcoholism (20% vs. 5%), drug abuse (17% vs. 5%), panic disorder (22% vs. 2%), generalized anxiety (14% vs. 5%), and eating disorders (12% vs. apparently none). Women writers, like men, suffered more bipolar illness and depression, but they also had had more problems with alcohol, were more suicidal, and had a lower life expectancy than other eminent professionals.

Nancy Andreason conducted structured interviews with 30 faculty members at the Iowa workshop over a period of 15 years. She performed a psychiatric diagnosis of both writers and their relatives, comparing them with a matched control group. She concluded that 24 of the 30 writers (80%) suffered from an affective disorder compared to nine (30%) of the control sample. She diagnosed 13 writers with a bipolar disorder and 11 with a major depressive disorder. In fact, two writers committed suicide while the study was taking place. Using the family history method, she also diagnosed the writers as having many more first-degree relatives with affective disorders and creative ability. Andreason recognized the limitations of her study, including the fact that she was cognizant of the writers and the controls. Also, writers might have more awareness

of affective illness both in themselves and in their relatives. She also commented that the degree of illness diagnosed might be exaggerated by the broad definition of bipolar illness in the DSM. Andreason was the sole interviewer and this particular group of writers may have turned to teaching because of depression.

Kay Jamison interviewed 47 British prize-winning writers and artists with a mean age of 53.2 years, asking them if they had been treated for mental illness. She discovered that 38% had been treated for affective illness at some point, 23.4% had taken antidepressants, and 6.4% had been diagnosed as manic-depressive (all poets). She compared this with 'normal lifetime rates' of 5% for depression and 1% for manic-depression.

The most comprehensive face to face study of professional writers was analyzed by Frank Barron, who, with other psychologists, interviewed and psychologically tested 30 professional writers nominated by the faculty of the University of California at Berkeley. Also included in this study were 26 'successful and productive' student writers and nonwriters. Barron tested for the presence of psychopathology by administering the Minnesota Multiphasic Personality Inventory. He found the most eminent writers scored high on scales measuring schizoid, depressive, hysterical, and psychopathic tendencies and in terms of femininity of interest pattern. However, these writers also registered higher scores on ego strength, so Barron concluded that while they suffered psychological turmoil, they also possessed more resources to deal with it. He felt this conclusion was reinforced by their social behavior since they presented themselves as clearly effective people with pride and distinctiveness while sometimes showing pain, protest, distance, and withdrawal, as well as being very emotional. Barron's study warrants replication with a contemporary group of writers because his conclusions might vary with subjects who lived in a different time frame.

There is also evidence that more successful writers who win Nobel Prizes and Pulitzer Prizes may be more likely to have mental illness. James Kaufman found similar results in two historiometric studies of 986 twentieth century writers and 889 writers who lived from 1600–2000. He concluded that: "In both studies, both types of prize-winners were more likely to suffer from mental illness than nonwinners. In addition, Nobel Prize winners were more likely to suffer from alcoholism . . . and experience a personal tragedy" (2000–2001: 305). A partial list of writers thought to have serious mental illness problems are listed in Table 1.

Ludwig suggested that writers demonstrate more psychopathology because writing and poetry rely on a 'personal vision' which is based on an internal subjective experience as opposed to science where more stability may be required to do work that has 'predictability, replicability, reliability, and testability.' The arts tolerate eccentric and irrational behavior much more readily than other professions. In fact, the creative writer's uniqueness is his or her stock in trade, and it takes a strong, independent personality to go one's own way. The characteristics that support this kind of abnormality are similar to the traits that characterize psychotic behavior.

There is also the distinct possibility that the characteristics of mental illness can be a detriment or benefit to creativity, depending on the individual case. For example, creative writers and poets may be far more sensitive to their emotions. Freud

Edmund Spencer (poetry/nonfiction)
August Strindberg (playwright/fiction/poetry)
Jonathan Swift (fiction/nonfiction/poetry)
Torquato Tasso (poetry/playwright/nonfiction)
Alfred Tennyson (poetry/playwright)
Leo Tolstoy (fiction/nonfiction/playwright)
Virginia Woolf (fiction/nonfiction)

Note: Many authors are classified as having mental illness automatically if they demonstrated heavy use of alcohol or drugs.

Sources: Ludwig, Magill, Prentky, Simonton, and others.

felt writers use fantasy to satisfy these needs. This anticipates other researchers who concluded the difference that composes what has been called the thin line between genius and madness is control. This point of view acknowledges that creative writers

may at times exhibit traits of mental illness, but argues they are essentially healthy because they can make critical judgments about their thoughts and work that would be impossible if they were truly pathological. Other researchers take the opposite position that psychotic thinking is an essential ingredient in creativity.

A third possibility accepts both psychopathology and creativity as ingredients which may vary along a continuum. At times creativity and schizophrenia may be inextricably linked together in varying degrees. Examples include the poet Holderlin, who was diagnosed as schizophrenic; Strindberg, who had a schizoaffective disorder; and writers who displayed a schizoid or schizothymic temperament, including Baudelaire, Kafka, and Beckett. It may be the schizoid or schizotypal propensities and world view which gave these writers' creative contribution its uniqueness.

Hypomanic traits have been cited as a positive force giving some writers energy, concentration, and confidence which enhanced their work. Depression inspired a small percentage of writers to work harder, perhaps attempting to escape their pain. Other writers such as Edgar Allan Poe used their dark moods as a source for some of their best work.

However, most writers with mental illness paid a heavy price in both their personal and their professional lives. Most reports by psychiatrists, psychologists, and writers indicate that being in the throes of mental illness is not a good place to work. Richard Berlin argued that: "Severe depression interferes with motivation, energy, drive realistic self-assessment, and pleasure" (2008: 4). Sylvia Plath said "When you are insane, you are busy being insane all the time . . . When I was crazy, that's all I was" (Flaherty as cited in Berlin, 2008: 4), Ezra Pound, Virginia Woolf and Sylvia Plath spent parts of their lives in mental institutions. Depression and manic-depression hampered the ability of many eminent writers, including Joseph Conrad, Leo Tolstoy, John Ruskin, and Ernest Hemingway.

Summing up, there are impressive indications that eminent writers as a group suffer more problems than other eminent creators or the general population. Despite the robustness of the statistics, they must be considered cautiously. Diagnoses have often been made posthumously using loose and inconsistent diagnostic criteria. In many cases the validity of a diagnosis of mental illness, alcoholism, or suicide cannot be verified. In addition, solid statistical evidence of the extent of mental illness, alcoholism, and suicide in the general population is still far from precise. Finally, it is possible writers with dramatic lives and early deaths are more likely to become eminent and have biographies written about them.

Suicide

Individuals who have problems with traumatic childhood loss, mental illness, alcoholism, and drug abuse are more likely to commit suicide, so it is not surprising the suicide rate among writers is higher than average. Difficulty with their writing is a factor contributing to writers' suicides. A partial list of writers who are believed to have committed suicide is in [Table 2](#).

In Ludwig's study, eminent people in general were more likely to commit suicide (4.4%) than the general population, which had an estimated rate of 1.0 to 1.4%. However, 20% of the poets were considered suicides. Fiction writers had an

average rate of suicides while nonfiction writers were below average. Ludwig proposed that emotional problems often interfered with creative productivity, but actually improved performance for 16% of eminent creative people by increasing productivity, overcoming writing blocks, and generating new ideas or better performances. The Goetzels found that 11% of writers committed suicide compared to 5% of their total sample.

Poets are more at risk than other groups and female poets represent the highest percentage of writers who commit suicide. James Kaufman and John Baer pointed out that female poets are introspective and the expressive nature and style of their poetry does not provide the health benefits of other kinds of writing. They cited other salient reasons including the implicit expectations of illness by the gatekeepers who evaluate poetry, the higher evidence of mental illness in female poets and the fact that poets tend to peak at an earlier age when bipolar illness and other mood disorders are more likely to strike.

Substance Abuse

Alcoholism has been a problem for many accomplished writers, including Nobel prize-winning authors Sinclair Lewis, Eugene O'Neill, and William Faulkner. The generation of American expatriate writers in post-First World War Paris that included Ernest Hemingway and F. Scott Fitzgerald

glamorized and romanticized drinking, making it a more sophisticated and respectable behavior. A partial list of alcoholic writers includes James Agee, Charles Bukowski, Truman Capote, Raymond Chandler, John Cheever, Dashiell Hammet, O. Henry, James Joyce, Jack Kerouac, Norman Mailer, Dorothy Parker, Edgar Allen Poe, John Steinbeck, Robert Louis Stevenson, William Styron, Dylan Thomas, Tennessee Williams, and Thomas Wolfe, Writers who used their drinking experiences for major works include Eugene O'Neill (*The Iceman Cometh*), William Burroughs (*Naked Lunch*), and Malcolm Lowry (*Under the Volcano*). Jack London wrote an alcoholic memoir (*John Barleycorn: Alcoholic Memoirs*) and Charles Bukowski's semi-autobiographical fiction and poetry were filled with his alcoholic experiences.

Arthur Rothenberg reviewed biographical and autobiographical data of writers known for their use of alcohol. He found very few did their actual writing or their thinking about writing, while under the influence of alcohol. In Ludwig's study of the biographies of 34 well known heavy-drinking writers, artists, and composer/performers, he found that alcohol negatively affected the work of 75%, especially as the drinking continued. Long-term drinking has physiological effects which directly hinder the concentration required of creative individuals. However, Ludwig believed that drinking actually benefited 9% of the subjects. Writers such as Hemingway, O. Henry, Raymond Chandler, and John O'Hara claimed that drinking improved the quality of their writing. Many writers recognized they could not write well while they were drinking. F. Scott Fitzgerald and Ring Lardner said they went on the wagon when they worked.

Anja Koski-Jannes reviewed 60 interviews with prominent Finnish writers who started writing between the 1920s and 1950s. Only 32 writers commented on their use of alcohol while they wrote since this was not a primary question in the interviews. Writers who used alcohol occasionally saw it as an aid in getting started or a stimulus when they were tired. Duplicating results of studies in England and the United States, poets reported more alcohol use than other types of writers. The most heavy use for all writers occurred between writing projects.

Immediately after a project was finished, writers reported they felt "empty, depressed and dissatisfied with themselves." They considered going out and drinking as a way to loosen up and relax, make social contacts with other writers, and generate new ideas. Writers also said they used alcohol to dissociate themselves from common concerns, and to facilitate the writing process. Koski-Jannes suggested that among the reasons writers use alcohol frequently are that the job is insecure, highly valued but poorly paid (at least in Finland), and the profession is subject to conflicting expectation from the reading public, critics and the writer her or herself (lose publicity pressures). As actual work it is unstable, lonely and at times emotionally highly demanding. Because of the marginality of this profession the identity of the writer is continually at stake (1985: 131).

These comments sum up the hazards of the job mentioned by a number of researchers. However, it does not explain why some writers respond to these pressures by drinking heavily while other writers drink in moderation or abstain. A few researchers have attempted to determine if alcohol facilitates creative writing under laboratory conditions. There were

indications that alcohol significantly increased the number of words produced, which confirms anecdotal accounts of writers who found alcohol an aid in writing. However, these studies did not examine professional writers, so any determination of the quality of thinking under actual working conditions remains unknown.

Often the term 'depression' is mentioned when it comes to writers who drink, which indicates that it may be used as a form of self-medication. If, in fact, more writers tend to be alcoholics than the general population, it is still not clear if the job makes writers depressed or depressed people are more likely to choose writing as a profession. Since most alcoholic writers were drinking before they started writing, perhaps professional writing was attractive because it allowed the individual the freedom to continue drinking. It is also possible that writing, like alcohol, serves as a way to escape negative feelings. A questionnaire given to writers on just this topic indicated that writers experience positive emotions significantly more often than negative emotions when writing. Furthermore, during the actual writing process, positive emotions tended to intensify, whereas negative emotions resisted change.

Ludwig's analysis indicated that poets and fiction writers trail only musicians and theatrical performers when it comes to drug use and abuse. Coleridge allegedly wrote about the palace of Kublai Khan while on opium; Keats tried the drug and described his experience. Elizabeth Barret Browning, Louisa May Alcott, and Jean Cocteau used opium. Aldous Huxley made no secret of his fondness for mescaline, which he wrote about in *The Doors of Perception*. Phillip K. Dick was addicted to amphetamines. Stephen King wrote in 2000 about being hooked on alcohol, cocaine, and prescription medicines.

It's impossible to accurately measure the level of drug use because, aside from the question of legality, some writers might be afraid their reputations would suffer if they publicly admitted they used drugs. As times change, writers' use of alcohol and drugs may change. Recent studies challenge the popular notion that creatively successful individuals lead excessive life styles. A survey of 22 writers, 27 artists, 12 musicians, and 25 controls about use of cocaine, marijuana, alcohol, etc. found no significant difference in the use of most substances between groups. However, a high rate of heavy use (23%), a small sample, and an even smaller control group preclude any definitive conclusions.

Life Span

Researchers concluded the stresses caused by being a professional writer result in a measurably lower life expectancy. A comparison of the age of death of 160 writers with that of 80 members of nine other creative occupations found that writers died at an average age of 61.7 years, which was 8.3 years less than composers and painters. Several hypotheses have been put forward to explain the cause of writers dying at an earlier age:

1. The theory that poets produce their major works at a younger age so they could die at a younger age and still be considered eminent in their field.
2. The differential-resources hypotheses, which suggests the lower financial rewards and standard of living in the literary arts results in a shorter life expectancy.

3. The stimulation–deprivation explanation which posits the meager financial rewards and sensory stimulation found in writing leads to risk-taking behaviour elsewhere.

A study by Vincent Cassandro found creative writers living an average of 62 years, which was three to seven years less than contemporaries in other disciplines. Scientists and inventors lived the longest. Cassandro concluded evidence supported the first two hypotheses, but not the third. He also made the logical link between a writer's psychopathology and a lower life expectancy. This is exemplified by the fact that poets are definitely more at risk than fiction and nonfiction writers. In 2003, Kaufman (2003) found this higher risks for poets cut across cultures in a study that looked at 2000 American, Chinese, Turkish, and Eastern European writers. This is not surprising in view of the fact that poets suffer more mental illness, substance abuse problems and suicide.

Cassandro's study offered significant evidence that the more writers diversified, the longer they lived. However, the sample was of subjects born no later than 1800 and thus might not generalize to the twenty-first century. Similarly, the findings might not apply to less eminent creative people or for writers in different fields. In 2009, Steven Pritzker and David McGarva found that Academy Award winning screenwriters lived to an average age of 72 although it has slipped below 70 since the 1970s. More in-depth research verifying the actual economic status of the creators studied, the actual cause of death, and the interaction of psychopathology upon these variables could help build knowledge in this area.

The Creative Process

Motivation and Personality

Why do writers write? It has been proposed that mental disturbances contribute to a state of 'psychological unease' which generates creative tension that is relieved by constant work, and that creators who do not have emotional problems are able to internally generate this unease. Others have theorized that writing may satisfy a biological drive, a search for meaning, or a means to fame and fortune. Barron theorized that writers are constantly creating a universe of meaning. This need to find meaning in life may be based on childhoods in which writers felt isolated and unhappy. This theory could explain why so many writers find the act of writing difficult. Creating a world that reveals lasting truths is bound to be frustrating as the writer searches for the right words.

However, despite all the pressures and frustrations, many writers have found great satisfaction in their work. For some, writing provides an escape from the pressures of life, offering a place where he or she is in control. Positive aspects frequently mentioned include the pleasure in discovering more about themselves and making new intellectual and emotional connections, feeling they have a real purpose, communicating with others and sharing their reactions when they find something which represents some underlying 'truth' about life, and the enjoyment of working with words. Some individuals found a long-sought sense of identity when they became writers.

Two motivations to write which have not been explored in depth are fame and fortune. Research in experimental settings has indicated that the relationship between intrinsic motivation and extrinsic motivation varies according to circumstances. It is probable that in the real world fantasies of celebrity and wealth helped some writers keep working through the lean times. Economic necessity motivated some writers. Dostoyevsky produced some of his best work when he needed money.

Many novelists and playwrights in the twentieth Century took lucrative offers from movie studios. Some including Fitzgerald and Faulkner felt that they 'sold out' to Hollywood where they had no control over their work. Usually they wrote bitterly about the experience.

Fame, once achieved, has been a part of the career fabric for many authors who enjoyed the attention. Ernest Hemingway's macho image helped sell his work while giving him ego gratification. However, fame also creates tremendous pressure. Expectations can become so high that writers become blocked. Writing became especially competitive in the 1920s when writing a great novel was not enough – it had to be a best seller.

Today's authors are expected to sell themselves on talk shows and do interviews so they can generate enough publicity to become a 'name brand.' The alcohol and drug problems many writers experience may be exacerbated by the drive for success, prestige, fame, and money, and the burden put on the creative self.

Work Habits

Creative writing may be sparked in many ways (e.g., a glimpse of a person or imagining a scene) and inevitably encompasses autobiographical elements. Once the subject is chosen, some prolific writers such as Stephan King can produce work with incredible speed. Isaac Asimov reported he would write at the 90 words a minute he could type, and stated he wrote most nonfiction books in 70 hours. However, many writers struggle finding the form which fulfills their vision.

Writers' work habits are as individual and idiosyncratic as their work. Some professional writers discipline themselves by treating writing as a nine to five job. Others may give themselves a daily quota of words or pages to fill. There are writers who like to isolate themselves while others enjoy working in cafes. Some write a specific number of pages every day while others procrastinate until they are faced with a deadline and then put in marathon hours.

Most writing decisions offer a number of choices, so often writers develop different drafts of stories and scenes, learning as they rewrite what works for them and what must be changed. During this evolutionary process their original perceptions may radically shift – a minor character may grow into a central figure, or the theme of a story may go in a completely different direction.

Thus the creative process in writing is usually not linear, but rather a series of steps that are repeated over and over as refinements are made. Many writers will look for feedback from one or more trusted sources while the work is in progress. Some writers may complete hundreds of pages and decide the idea does not work at all. The most constructive work is done in a state of total concentration which almost seems effortless

at the time, referred to as 'flow.' The author must remain open to the message whispered by the unconscious, while at the same time maintaining critical judgment.

Writer's Block

A common complaint among both amateur and professional writers is the inability to work known as writer's block. This experience is intimately connected to the uncertainty and tension inherent in facing a blank page every day. Factors contributing to writer's block are self-doubt, perfectionism, procrastination, unrealistic expectations, and fear of failure. Some strategies suggested for countering blocks include writing anything (even about being blocked), setting up a regular time and place to write, isolating oneself from distractions, stopping writing when there is some momentum left so the work can be continued the following day, going to another project for a while, and using positive self talk. The fact that even blocked writers may eventually produce important work is exemplified by Karl Marx, who spent 18 years writing the first volume of *Das Kapital*.

Collaborative Writing

The act of writing is usually an internal process so it has been difficult to make independent observations of elements that encourage or discourage creativity. Research about collaborative writing in television script writing, indicates that specific elements encourage creativity, including the willingness to take risks and providing a safe atmosphere where members of the group build upon each others' ideas while they are free to argue (Pritzker, 1997). Negatives include unresolved emotional conflict between the writer and supervisors, differences in communication styles, settling quickly on a predictable story, and the tendency of executives to demand massive rewrites generating fear of change and fatigue.

Creative Writing as an Aid to Mental Health

Writing has been used as a tool for self-healing by both amateur and professional writers for thousands of years. Ronald Kellogg observed that well-known writers often talk about constructing meaning. He quoted E. M. Forster who had one of his characters say: "How do I know what I think until I see what I say?" (1994: 25).

James Pennebaker and other researchers completed a number of studies indicating that writing about personally significant events with emotional implications, even for a short time, can generate significant benefits. Pennebaker summarized various studies which indicated:

- Improved biological effects represented by enhanced immune system functioning and healthier medical markers such as lower blood pressure and reduced stress levels,
- Psychological impact including improved short and long-term mood changes.
- Behavioral changes such as better grades at school, greater success in finding work and more effective social skills (2004: 7–10).

However, as Stephen Lepore and Joshua Smyth pointed out, a certain degree of skepticism is probably healthy since this is a relatively new area of research.

Creative Writing in Institutions

Creative writing is used as a tool to help prisoners and patients in mental institutions. Cognitive researchers concluded that creative writing takes tremendous effort and requires a great deal of attention; thus for some troubled people it helps center the thinking process and provides insight into problems. William Styron and Art Buchwald wrote about their deep depression as a catharsis and with the hope the public would understand more about the debilitating nature of their illness. Political prisoners such as Thomas Paine, John Bunyan, and Daniel Defoe used their time in jail to write books that furthered their own cause. Prisoners committed for other crimes who wrote notable works while in jail include O. Henry, William Penn, Marco Polo, Oscar Wilde, Eldredge Cleaver, and Malcolm X. The Marquis de Sade completed the circuit since he began his writing career in prison and continued it in a mental institution.

Conclusions

Work on writing and creativity has consistently indicated that many writers suffer problems with psychopathology, alcoholism, and drug abuse. The next step is to go beyond the interesting and logical theories proposed for this connection and develop verifiable causal explanations.

Information on the life expectancy of writers needs further investigation. If writing inherently contains occupational hazards, then therapists and creative writing teachers can develop a proactive stance to help some of their clients understand and cope with the stress of the job and deal with their personal demons.

Much of the research has concentrated on eminent writers. Learning more about professional writers who are more 'ordinary' can widen our knowledge and possibly lead to training which can encourage creativity.

While a great deal of attention has been paid to dysfunctional writers, the healthy writer (if one exists) is barely represented in the literature. It might prove worthwhile to look closely at the lives of writers with less dramatic histories since they may serve as positive models other writers may emulate.

Glossary

Anomalies According to Kuhn's theory of scientific revolutions, anomalies occur during normal science when puzzle-solving research obtains results that conflict with the prevailing paradigm. Sometimes these anomalies can eventually be accommodated by the paradigm, and even prove to confirm the paradigm. Other times anomalies resist accommodation, and can lead to the discipline entering a crisis state that is only resolved by scientific revolutionaries who introduce a new paradigm.

External Zeitgeist Conditions that are extrinsic to a particular domain of creativity. Examples include political events, economic circumstances, and sociocultural conditions outside the discipline itself.

Generational time-series analysis A statistical method in which a transhistorical sample of eminent personalities gets assigned to consecutive 20-year periods and then subjected to various statistical analyses.

Internal Zeitgeist Conditions that are intrinsic to a particular domain of creativity. Examples include research paradigms in the sciences and stylistic conventions in the arts.

Multiples The event where two or more scientists (or inventors) independently come up with the same discovery (or invention). Some multiple discoveries and inventions are not just independent but also nearly simultaneous. The phenomenon has been traditionally used to define the doctrine of sociocultural determinism, the extreme form of Zeitgeist theory.

Ortgeist The 'spirit of the place,' just as the Zeitgeist is the 'spirit of the times.' This includes all political, economic, sociocultural, and disciplinary conditions characteristic of a given locale, such as a university, city, or nation. In practice, the term Zeitgeist is often used to encompass the Ortgeist. That inclusion occurs because the Zeitgeist only applies to a specific place as well as time.

Paradigms Theories, methods, and exemplary works that serve as models for research in normal science. Normal scientists are engaged in establishing and extending the paradigm, and do so through the practice of puzzle-solving research. Revolutionary scientists, in contrast, propose a new paradigm in order to resolve anomalies that have emerged in the application of the old paradigm.

Premordial cognition A key variable in Colin Martindale's theory of stylistic evolution. Originally termed primary process imagery, it concerns the cognitions associated with dream states, altered states of consciousness, fantasy, and basic drives, and sensations. It is to be distinguished from conceptual cognition or secondary process.

Premordial cognition is assessed using content analysis, most notably through Martindale's Regressive Imagery Dictionary.

Role-model availability In generational time-series analysis the number of creators in generation $g - 1$ (and perhaps also $g - 2$) for creators in generation g . Because creators in generation g are in their developmental period in generation $g - 1$, the number of creators in the latter period serves as an indicator of potential role models. The autocorrelation between consecutive generations thus indicates the impact of role-model availability.

Scientific revolutions Periods in the history of paradigmatic sciences in which the old paradigm is replaced with a new paradigm that resolves the anomalies that put the science in a crisis state. Once a revolution succeeds, the scientific discipline returns to the state of normal science in which practitioners engage in puzzle-solving research. Scientific revolutions include the Copernican model of the planets, Newtonian celestial mechanics, and Darwinian theory of evolution.

Sociocultural determinism The doctrine that the individual is totally influenced by the larger milieu. This milieu may include political, economic, social, and cultural conditions. In the specific case of creativity, advocates of sociocultural determinism argue that both the type and level of creative achievement is shaped by the Zeitgeist, both internal and external. Multiples are often taken as empirical proof of this position even though that inference has shown to be incorrect.

Stylistic change In artistic or aesthetic evolution when one set of stylistic conventions are replaced with another. All of the arts undergo such shifts. Cases include the shift from Baroque to Neo-Classicism, Neo-Classicism to Romanticism, and Romanticism to Modernism in literature, painting, sculpture, and music. Such shifts are roughly analogous to paradigm shifts in the sciences.

Introduction

In Shakespeare's *Twelfth Night* a character utters the famous lines "Some are born great, some achieve greatness, and others have greatness thrust upon them." The first option would seem to apply to royalty and aristocrats, and the second to the great geniuses who make history. The third possibility suggests that sometimes greatness is not a matter of being the right person but rather can be attributed to being at the right place at the right time. Even creators as outstanding as René Descartes, William Shakespeare, Leonardo da Vinci, and Ludwig van Beethoven are nothing more than products of larger sociocultural circumstances beyond their control. In a sense, geniuses are mere epiphenomena – effects rather than true causal agents. That is, geniuses are pawns of the *Zeitgeist*, a German word that literally means 'time spirit,' or 'spirit of the times.' The word 'Zeit' has the same origins as the English root 'tide' still seen in such words as eventide, Christmastide, and Shrovetide. And the German word 'Geist' has the same source as the English 'ghost,' which came from the Old English word for breadth or spirit. The term *Zeitgeist* is closely linked with *Ortgeist*, another German word that signifies 'spirit of the place.' In practice, the two terms can be used interchangeably. The near equivalence ensues from the fact that the 'spirit' is invariably confined to a particular time and place. For example, when we speak of the Age of Pericles we are simultaneously talking about a particular place (Athens) at a specific time (about 445–429 BCE) – the Athenian Golden Age. There was no Periclean Age in Rome, and even less in Africa, Asia, and the Americas. Hence, throughout this article *Zeitgeist* will be used in the inclusive sense to encompass the *Ortgeist* as well.

As the preceding example illustrates, the *Zeitgeist* is often associated with eponyms – names of persons that became labels for eras or periods in history. Other examples include the Elizabethan Age in England or the Age of Louis XIV in France. Even so, sometimes the *Zeitgeist* is identified by more impersonal names, such as Renaissance Italy or the British Industrial Revolution. The latter usage is more consistent with the tenor of the *Zeitgeist* theory of history. The expression Victorian Age seems to imply that the British Queen Victoria had something to do with the making of the age. Yet *Zeitgeist* advocates, such as Leo Tolstoy in his *War and Peace*, are emphatic that eponyms have no causal significance. On the contrary, the Queen was the pawn rather than agent of her age. Her sole contribution was to live long enough to provide an all-encompassing label for a whole period in history.

In its extreme form, *Zeitgeist* theory becomes equivalent to sociocultural determinism and reductionism. All individual behaviors, including creativity, is determined by social and cultural variables. As such, the individual is reduced to a set of norms, roles, and other factors that exist outside the person, and prior to the person. However, it is possible to acknowledge the impact of the *Zeitgeist* without adopting such an extremist stance. The *Zeitgeist* then provides a set of variables that join psychological and biological factors in the making of the creative genius.

To understand better how the *Zeitgeist* affects creativity, we must first recognize that the *Zeitgeist* assumes two forms: the internal and the external.

Internal Zeitgeist

At the level of everyday creative behavior, creativity can often be generic. Thus, a person who writes imaginative American haiku might also produce a creative collage. In contrast, high-level creativity tends to be much more domain specific. It is as unlikely that T. S. Elliot could have painted *Guernica* as it is improbable that Pablo Picasso could have penned 'The Waste Land.' Accordingly, to some extent the *Zeitgeist* must also be domain specific. The *Zeitgeist* associated with Newtonian or 'Classical' physics will have a far greater influence on the creativity of physicists than it will on the creativity of sculptors. Likewise, the *Zeitgeist* connected with Socialist Realism had a bigger impact on the arts than on mathematics.

One illustration of this domain-specific contingency is seen in the phenomenon of role-model availability. It has been long observed that creative genius is not randomly distributed across time and place. Instead, geniuses tend to congregate into temporally and geographically restricted clusters – the best of which are often called 'Golden Ages.' Moreover, these clusters take time to emerge and time to dissipate. Typically, a given civilization might begin with a few progenitor or precursor geniuses, and in successive generations the creativity attains a climax, after which activity trails off in a series of epigones or inferior successors. Hence, although the Golden Age of Greek philosophy is clearly defined by the apex represented by Socrates, Plato, and Aristotle, this peak was preceded by pre-Socratic thinkers and succeeded by post-Aristotelian thinkers of lesser merit – such as Democritus and Theophrastus, respectively.

Detailed generational time-series analyses have identified the basis for this clustering. Each generation of creators tends to build upon the work of the previous generation. As Plato builds upon Socrates, so does Aristotle build upon Plato. It is extremely rare for a creator to appear *de novo*, sans predecessors, and whenever that happens the creativity tends to be inferior to what occurs during the climax. In a nutshell, creative development is contingent on the availability of role models during the creator's childhood and adolescence, when the individual is acquiring creative potential. And, obviously, that role-model availability is most effective if its domain specific. Albert Einstein's creative potential is going to be fostered more by senior physicists than by older architects. When Newton famously said that he saw farther than the rest by standing on the shoulders of giants, he certainly meant figures like Kepler and Galileo.

Unfortunately, once the Golden Age attains the acme, subsequent generations tend to exhibit a progressive decline. The reasons for this decadence are complex, and probably in part domain specific. Alfred Kroeber, the cultural anthropologist, attributed the decline to 'pattern exhaustion.' After everything has been said within the constraints of a given cultural milieu, or *Zeitgeist*, there is no place to go next but down. Once painting has culminated in perfect photographic realism, then where can painters go next? They either must scramble to paint ever more exotic objects or they must find some alternative stylistic goal. Another disabling influence may be imitation. Too many potential creative geniuses of the post-climax generations may be tempted to imitate the masters of the Golden Age rather than risk developing their own unique voice. And

ultimately such imitation may be antithetical to genius, as argued by the philosopher Immanuel Kant. At the end of the Second World War the Dutch minor painter Han van Meegeren was revealed to have painted imitation Vermeers that art experts had actually certified as authentic. But rather than being hailed as an artistic genius he was condemned as a mere forger of fakes. It is one thing to create one's own distinctive style from scratch and quite another to ape the style of others.

Whatever the details, role-model availability exemplifies one way that the *Zeitgeist* operates to influence creativity in every generation and in every creative domain. In part, the *Zeitgeist* in any give period consists of the inventory of recent creative achievements that can inspire subsequent creativity. Below we turn to more specific processes that are confined to particular domains. We first look at the sciences, and then turn to the arts.

Scientific Creativity

Thomas Kuhn's *The Structure of Scientific Revolutions* presented a highly influential internalist theory of scientific discovery. The theory applies to paradigmatic disciplines in which practitioners exhibit a high theoretical and methodological consensus. An example would be physics which in the seventeenth and eighteenth centuries was largely governed by the Newtonian or 'classical' paradigm. Scientists operating within a paradigm are engaged in 'normal' science, a puzzle-solving enterprise that aspires to extend the paradigm's explanatory scope and precision. However, over time 'anomalies' begin to accumulate. These are results that do not fit within the accepted paradigm. On occasion, these anomalous findings can be assimilated. For example, Newtonian celestial mechanics managed to explain a perturbation in the orbit of the planet Uranus by predicting the existence of a new planet. When that planet, Neptune, was observed, it became a triumphal confirmation of the paradigm. Other times the anomalies cannot be easily assimilated without introducing post hoc alternations that undermine faith in the paradigm. For instance, an anomaly in the orbit of Mercury resisted all attempts at a Newtonian explanation (including the prediction of an unknown planet). If enough of these anomalies accumulate the discipline may enter a 'crisis' state that can only be resolved by the introduction of a new paradigm. These paradigm shifts are promoted by practitioners of 'revolutionary' science. An example was Albert Einstein's introduction of relativity theory in the early twentieth century. And the cycle continues. The key feature of this process is that the *Zeitgeist* is defined by the discipline (viz. the paradigm) rather than being determined by sociocultural factors outside the discipline, such as war.

Interestingly, normal scientists can be psychologically distinguished from revolutionary scientists. To illustrate, the latter are more prone to be laterborns and to exhibit higher rates and intensities of mental illness. So the paradigmatic *Zeitgeist* has psychological as well as disciplinary consequences.

Artistic Creativity

Like Kuhn, Colin Martindale was fascinated with disciplinary change, but in his case the focus was on stylistic change in the

arts, especially in literature. Just as the paradigmatic sciences show paradigm shifts, so do the arts display stylistic shifts. A Romantic poet does not write the same kind of poetry as a Neo-Classical poet. To explain these changes, Martindale proposed an evolutionary theory. The theory begins by assuming that all creators are operating with a given set of aesthetic conventions that define a particular style. However, creative individuals are also under pressure to maintain the 'arousal potential' of their products. This impetus means that they have to generate ever more novel and surprising works within the given style. To attain this end, creators have to increasingly rely on 'primary process' imagery (or primordial thinking). Yet after a few generations this cognitive regression goes so far that the stylistic constraints begin to break down. The style then becomes exhausted in a manner similar to Kroeber's concept of pattern exhaustion. The only salvation is to introduce a new style. Because the style itself is novel, arousal potential can be maintained without much regression into primary process. And the cycle then repeats.

Martindale has conducted a large number of empirical investigations that provide support for his evolutionary theory. Most notably he has used computerized content analyses to show that over the history of any given literary tradition both primary process imagery and stylistic change tend to exhibit inverse oscillations. When a new style is introduced primary process declines. At the same time, Martindale has shown that these stylistic changes are internal to a given art form. That is, such changes are affected very little by external events.

External Zeitgeist

The German philosopher Georg Wilhelm Friedrich Hegel argued that history was driven by a dialectic process involving pure ideas. A given ideational thesis would yield an antithesis which in its turn with produce a synthesis – and the latter would be a new thesis for the continuation of the cycle. Political, social, and economic systems were nothing more than manifestations of that intellectual history. In contrast, Karl Marx famously 'turned Hegel on his head' by arguing that the dialectic was materialistic rather than idealistic. In particular, the economic system, as defined by the means of production, underwent a dialectic process that drove history through the successive stages of slavery, feudalism, capitalism, and finally communism. In the Marxian view, the world of ideas – including both artistic and scientific creativity – was but the external consequence of the resulting economic conditions. Feudal art or science would have to be different than capitalist art or science because they reflected contrary materialistic circumstances. Needless to say, this reflectionist or externalist perspective is antithetical to the internalist positions discussed previously. It leads to a sociocultural determinism in which both paradigms and styles are epiphenomenal rather than causal. When artists in a communist state turn to 'Socialist Realism' it is not because the previous style had exhausted itself but rather because the new style better complies with the new economic milieu.

Although the extreme position is probably overstated, it remains true that creativity is not completely immune from the external *Zeitgeist*. The latter impact is evident in empirical

research on how political, economic, and sociocultural circumstances affect both the quantity and the quality of creativity observed at a particular point in time.

Quantity

The impact of the external Zeitgeist on the quantity of creativity can be assessed two main ways.

On the one hand, we can use generational time-series analysis to count the number of creators active in each time period, where the latter is most often taken as a 20-year interval. Specific political, social, economic, and cultural events or conditions can then be assessed in the same intervals. The relation between these two time series then provides information about the connection between the two measures. However, often the association between the two series is lagged rather than simultaneous. More precisely, the number of creators in generation g might be a function of the external Zeitgeist in generation $g - 1$. This lagged function would imply that the magnitude of creativity is contingent on the developmental experiences that future creators have in childhood and adolescence. As an illustration, for many domains of creativity the number of creators at generation g is a negative function of the level of political anarchy at generation $g - 1$, where the latter is gauged by political assassinations, military revolts, palace *coups d'état*, and the like. Another feature of the political Zeitgeist that may have a lagged effect is political fragmentation (i.e., the number of independent or sovereign states into which a given civilization is divided). Growing up under such conditions may enhance creative development, possibly via increased bilingualism and multiculturalism. In the same vein, civilizations tend to become more creative a generation or two after they have been exposed to influences from alien civilizations or cultures. In a nutshell, the aggregate level of creativity is prone to increase after an influx of sociocultural and linguistic heterogeneity.

On the other hand, we can use a smaller unit of time, such as a single year, to tabulate the number of creative products in a given temporal interval. This approach is clearly more refined. Shorter units of analysis allows for the possibility that the external Zeitgeist might have more finely-tuned effects. If certain extrinsic conditions can fluctuate rapidly from one year to the next, then their consequences will be overlooked when using larger aggregates. A prime example is the impact of war. Although war has no effect on the number of creators counted into 20-year periods, this dramatic condition does have a repercussion at the level of yearly tabulations. When war is followed by peace creators seem to make up for lost time, and thus create the works that were set aside during the military conflict. So the adverse impact is obliterated when the analysis expands from years to generations.

All in all, it is apparent that the quantitative implications of the external Zeitgeist are substantial. They can determine both the number of creators that appear in a given generation and the number of creative products that appear in a given year.

Quality

The qualitative impact of the Zeitgeist is perhaps even more interesting than the quantitative. During a specific period in

history, the number of creators in Chinese civilization might equal the number of creators in European civilization, and yet the products generated by these two sets of creators might be radically different in qualitative characteristics. In the case of painting, for example, Chinese painters might be creating highly idealistic landscapes that exist only in the artist's mind while European painters are creating highly realistic portraits of actual people.

Fortunately, some empirical research does indeed show that external conditions affect qualitative features of creative products. To illustrate, consider the following set of findings: (a) compositions in the classical repertoire exhibit distinct stylistic aspects depending on whether they were composed during peacetime or wartime conditions; (b) specific features of Greek ceramic paintings reflect the degree to which economic and political power was concentrated in a small proportion of people; and (c) the thematic material presented in plays corresponds to a noticeable degree with concurrent political events. These effects are all contemporaneous, whereas other external influences require a substantial delay. An especially interesting lagged effect is the polarizing effect of civil disturbances. One generation after a region has seen an increase in nationalistic revolts or political rebellions there tends to be a divergence in the positions advocated by notable philosophers. That is, thinkers who grew up under such circumstances have a higher likelihood of becoming proponents of diametrically opposed viewpoints. For instance, there will appear both extreme materialists and extreme idealists, extreme empiricists and extreme rationalists, and so forth.

To be sure, the correspondences are far from perfect. Many creators will be sufficiently individualistic that their work will not accurately reflect the external Zeitgeist. Even so, enough creators in any given generation conform enough that their products taken as a whole will represent their times.

Mixed Zeitgeist

Naturally, the foregoing represented extreme positions. The Zeitgeist is not exclusively external or internal. Rather, the two guises of the Zeitgeist operate together. Creativity in most domains is the joint function of both the internal and external Zeitgeist. That conclusion can be illustrated using both artistic and scientific creativity.

Artistic Creativity

Creativity in the arts is contingent on both types of Zeitgeist. This contingency is apparent in the empirical research on the thematic material in the compositions that make up the classical repertoire. On the one hand, it is clear that themes or melodies undergo stylistic changes, just as in literary creativity. The music of the Baroque period is identifiably different from the music of the Classical or Romanic periods. Moreover, the evidence suggests that these stylistic shifts are partly driven by the same kind of processes that Martindale discusses in his evolutionary theory. For example, because of the constant pressure on composers to be original, their melodies tend to become more novel, surprising, and unpredictable over the

course of their careers. This longitudinal trend then induces a historical trend: Melodic originality tends to increase over time. On the other hand, the research also shows that the nature of the melodic material also depends on the larger sociocultural conditions. For instance, melodies become more unpredictable and variable when a composition is created under wartime circumstances – particularly if the composer is active near the war zone. There is even an Ortgeist effect. Provincial composers who were born and raised far from the music centers of their day tend to create less strikingly original themes relative to cosmopolitan composers who emerged from one of the centers of music activity.

The foregoing illustration concerns qualitative effects operating on single creative products. Yet the internal and external Zeitgeist can also exert joint quantitative effects on individual creators. This twofold influence is apparent in research on the Japanese literary tradition. One peculiarity of this literature is the conspicuous presence of female writers, particularly during the Golden Age represented by the Heian period. As a case in point, Murasaki Shikibu, who is credited with writing the world's first true novel, has something of the status of William Shakespeare in English literature. Even so, it is also clear that the appearance of outstanding female literary creators fluctuated throughout Japan's history, and in some periods they would disappear altogether. It turns out that both internal and external factors are involved. In the first instance, female literary greats are most likely to emerge in those generations that feature male literary greats. Stated differently, only when Japanese culture favored literature as a form of creative expression will women have a high probability of making a contribution. In contrast, the appearance of female writers is uniquely discouraged by such extraneous conditions as Confucianist ideology. Because Confucianism promotes a hierarchical system that places women in an inferior position, it harms female creativity but not male creativity. Indeed, the dominance of Confucian ideas inhibits female achievements in other domains besides literature.

Scientific Creativity

From time to time two or more scientists will make the same discovery independently of each other. Well-known examples include the calculus by Newton and Leibniz, the conservation of energy by Mayer, Helmholtz, and Joule, the theory of evolution by natural selection by Darwin and Wallace, and the plague bacillus by Yersin and Kitasato. Likewise, it sometimes happens that two or more inventors will independently create the same invention. Instances include the ophthalmoscope by Babbage, Helmholtz, and Anagnostakis, photography by Daguerre and Talbot, and incandescent lamp carbon filament by Swan and Edison. Such events have been termed multiple discoveries or inventions, or just plain multiples. What renders these occasions especially dramatic is that sometimes the multiples are virtually simultaneous. Alexander Bell and Elisha Gray showed up at the US Patent Office with their respective inventions of the telephone on the exact same day! Furthermore, many more than two rival claimants may be involved. The dynamo may have had as many as nine independent inventors. Nor are these multiples rare. Examples run into the hundreds.

This phenomenon has often been taken as prime evidence for sociocultural determinism, the strongest form of Zeitgeist theory. Although research shows that this inference is unjustified – multiples are largely chance events – it remains true that they illustrate the influence of the Zeitgeist. The Zeitgeist provides the necessary but not sufficient conditions for a given discovery or invention. Calculus presupposes an analytic geometry, which in its turn depends on the prior advent of algebra, the latter being contingent on the previous existence of arithmetic. In this case, this sequence of dependencies illustrates the internal Zeitgeist within the discipline of mathematics. Yet on occasion the internal Zeitgeist will be joined by the external Zeitgeist, creating a mixed effect. A particularly dramatic example is the atomic bomb. The internal Zeitgeist in nuclear physics had already demonstrated the theoretical possibility of such a weapon. But it took the external Zeitgeist, in the form of the Second World War, for physicists to receive the tremendous resources required to convert this possibility into a reality. Although the atomic bomb was not a multiple, it might have become so had not the defeat of Germany terminated its own program.

Individual Versus Society

Too often the Zeitgeist is evoked to minimize the importance of the creative individual, even the creative genius. This derogation is especially commonplace in many discussions of multiples. If both Newton and Leibniz came up with the calculus, then the calculus must have been 'in the air' just ripe for the picking. However, this implication does not follow from the evidence. Nor do the other findings mentioned earlier in this article serve to dethrone the individual creator. The creative person remains for three main reasons.

First, two individuals can be born in the same place and time – identical Ortgeist and Zeitgeist – but still exhibit greatly differing degrees of creativity. One might become a universally hailed genius while the other becomes an obscure also-ran. Conversely, two persons of comparable achievements might be born in very different times and places. Consider the four scientists credited with discovering the Mendelian laws of genetics: Mendel, born 1822 in Heinzendorf bei Odrau, Austria (now the Czech Republic); Hugo de Vries, born 1848 in Haarlem, Netherlands; Carl Correns, born 1864 in München, Germany; and Erich von Tschermak-Seysenegg, born 1871 in Vienna, Austria.

Second, even when exact contemporaries and compatriots exhibit equal magnitudes of creativity, that creativity may appear in totally distinct domains of achievement. Where one becomes a Nobel laureate in physics, the other might become a laureate in literature. Any large metropolitan area in any given year will give birth to dozens if not hundreds of creative individuals who make their respective contributions to radically different domains.

Third, the level and type of creativity is determined by numerous variables that are inherent in the singular creator. Indeed, these non-Zeitgeist influences explain the previous two observations. The most obvious influence is genetic inheritance, which will affect both the type and magnitude of creativity. In addition, different creators will grow up under distinct

family backgrounds. In fact, even if two creative individuals came from the same household, they might differ because of their birth order. As an example, the Tolman family in West Newton, Massachusetts, had two sons born five years apart. The oldest, Richard, became a famous mathematical physicist, whereas the youngest, Edward, became a famous psychologist. Beyond the family there are various other developmental influences, such as education, mentors and role models, friends and colleagues, work environments, etc. This huge inventory of developmental experiences serves to individualize each creator. Consequently, each creator becomes something more than just a pliable pawn of the Zeitgeist.

Glossary

Beginner's mind The many possibilities regarding meditation in the mind of a beginning mediator.

Enlightenment A final blessed state marked by the absence of desire or suffering.

Koan A paradoxical question that cannot be answered using ordinary logic.

Mushin The state of 'no mind' or 'no ego' in which true emptiness is achieved.

Nirvana An advanced state of enlightenment in which desire, frustration, and ignorance are dissipated so absolute silence and stillness reign.

Samadhi The state in which consciousness is stopped and the individual is no longer aware of time, space, and causation.

Satori The moment of enlightenment when one sees into one's own nature.

Zazen Zen sitting meditation.

Zen A Japanese sect of Mahayana Buddhism that aims at enlightenment by direct intuition through meditation.

Brief History of Zen Buddhism

Prince Guatama was born near the border of Nepal and India in approximately the sixth century BC. His wealthy father gave him every luxury and kept him protected within the palace walls. When the prince finally left his sheltered life, he was very upset when he encountered sickness, old age, and death. He met a holy man who seemed happy despite the problems that surrounded him, so the prince decided he would seek his own liberation. He became a holy man, wandering the country without finding peace. Finally he vowed to sit on a straw mat under a bodhi tree until he found an answer. He sat there for six days. On the morning of the seventh day, he awakened to the morning star and became enlightened.

Prince Guatama became known as The Buddha.

Tathagata developed the Four Noble Truths, which emphasized that life's suffering was engendered by selfish craving that could be overcome through following the eightfold path of right understanding, purpose, speech, conduct, livelihood, effort, alertness, and concentration. The detachment of a solitary life led to liberation. The ultimate goal was achieving Nirvana, which represented a state of undisturbed peace.

The founder of Zen Buddhism was The Bodhidharma who was the twenty-eighth patriarch of Indian Buddhism. He arrived in China about AD 520. The Bodhidharma meditated facing a wall for nine years before becoming a teacher. His teaching was based on the principles of Mahayana Buddhism, which emphasized helping others and concrete experience. His disciples continued teaching in China.

Zen became recognized as a separate branch of Buddhism about AD 700 during the time of the patriarch Hui-neng. Hui-neng stressed the concept of emptiness, which minimized the importance of the individual ego in a world where everything and everybody are connected and constantly changing.

Suspicion of language is a basic tenet of Buddhism. The Bodhidharma called for 'no dependence on words and letters' but 'direct pointing to the real person, seeing into one's nature and attainment of Buddhahood.' Buddha stated that all humans are inherently enlightened; however, there is a need to practice in order to remove the obstacles to experiencing satori. Satori is reached through the study of koans, meditation, and living a purposeful life. 'Chop wood, drink water' – concentrate on what is necessary at this moment. It takes most people a great deal of training to calm what is called in India 'monkey mind,' the constant chatter of thoughts, for even a few moments. Zazen is a form of meditation in which concentration on breathing and calming the mind helps the practitioner lose awareness of the body. The goal is to reach a state where time, space, and causation, as the framework of consciousness, drop away.

Koans are a unique method of teaching. The student is assigned a koan – for example, 'What is the meaning of Mu?' The individual repeats the koan over and over during meditation until suddenly its truth is revealed.

Reaching enlightenment is a long, challenging path for most people. Philip Kapleau suggested that the three essential qualities necessary for enlightenment include (1) strong faith, (2) a strong doubt based on the imperfect state of the individual and the world compared to the idealistic image, and (3) strong determination to dispel this doubt with the whole force of one's energy and will.

Enlightened individuals are encouraged to participate in life. D. T. Suzuki stated that "the object of Zen training consists in making us realize that Zen is our daily experience and that it is not something put in from the outside." The enlightened individual interacts with everybody in a different way because the desire for ego gratification and material things no longer dominate the individual's thinking. Success and failure, happiness and unhappiness all become an accepted part of life.

Zen and Creativity in China and Japan

By AD 800 Zen was widely practiced in China. Zen's influence on culture was relatively minor. It contributed to Chinese philosophy in the Sung dynasty and a form of thirteenth century asymmetrical painting called *one corner* that was eventually exported to Japan. This inspired the *thrifty brush* style of Japanese painting that reflected the simplicity of Zen experience. Zen gardens and calligraphy also originated in China, but it was in Japan where Zen had the most impact on culture. Zen monasteries became the primary source of learning and art for the upper classes in Japan. Creativity was inherent in the teaching practiced by the Zen masters who used improvisational methods specifically tailored to the individual student.

The model of discipline and concentration required in Zen influenced other aspects of life. Training was often done by a master teacher similar to a roshi or Zen teacher. The idea of reaching *mushin*, a state of 'no mind,' penetrated the arts in Japan and stimulated creativity in many areas. *Mushin* represents the highest state of consciousness with no thoughts or judgments clouding the mind. Students practiced calligraphy, painting, or archery until the routine requirements – the moving of the pen or brush or the firing of the bow – could be accomplished automatically without thought. This training took many years because conscious control was not surrendered easily. Students without self-consciousness could completely absorb themselves in the moment, allowing intuition rather than intellect to control their process. When the mind was clear with no duality in the way, true human nature could take over and the artist knew where the brush was supposed to go. Some professions Zen influenced include the following.

Architecture and Design

Many great Zen temples began as imperial palaces and castles. They are noteworthy because they reflect and respect the unique beauty of the gardens that surround them.

The Japanese tea room, which originated in the fifteenth century, is an excellent example of how Zen deeply influenced many aspects of Japanese culture. The tea ceremony is a ritual designed as a diversion from the everyday world. Each tea room is built specifically for the individual tea master.

The ceremony begins with a walk through a garden where stepping stones form an asymmetrical path. The walk through a tea garden is intended to foster recollection and inner peace. The tea room's construction is deliberately delicate, consisting of bamboo supports and thatched roofs. The interior is strikingly simple with a fire pit, tatami mats, and a hanging scroll or some other object of art. Tea ceramics are a Japanese art form. Each item is carefully chosen to be part of a group. After the special tea is brewed and drunk, the tea master and guests may discuss each implement or the beauty of nature. Ordinary business matters are left outside in this special world. The simplicity of tearoom decor has influenced the design of functional things, including kitchen implements, floor mats, textiles, and common bowls and cups.

Calligraphy

Calligraphy originated in China in the third century AD. The ink (*sumi*) was mixed using an inkstand to grind an ink block made of lampblack and glue. Sometimes poetry was created spontaneously, which contributed to the development of haiku.

The first Zen calligrapher was Huang T'ing-chien (1045–1105) who became enlightened and recognized this changed the quality of his writing. Dogen Kigen (1200–1253), a legendary Zen master who founded the Soto sect, was a highly skilled calligrapher, and emphasized the importance of meditation.

Art

Ashikaga monochrome ink painting began as a natural extension of calligraphy. The black ink can be mixed in various shades that suggest the perception of color. As stated by T. Hoover, the purpose of Zen painting is to penetrate beyond the perceptions of the rational mind, to show nature's essence. The artist paints the enlightenment of the moment, and therefore has no time to labor over each stroke. Absolute concentration is crucial because no retouching can be done. The artist never pauses to evaluate his work. The ink flows in an unending flurry of strokes producing a sense of rhythm, movement, form, and the artist's vision of life's inner music.

This type of painting began in the Sung dynasty in China as a rebellion against conventional art similar to the abstract expressionist movement. Ch'an monks threw ink and rubbed it in by hand or using their hair. Three types of schools emerged. Zenkiga emphasized Zen parables, insight, and practice. Chinz specialized in portraits of well-known Zen teachers.

A third school focused on landscape painting with a very specific set of rules including which items were usually present (mountains, trees, rocks, etc.). Each painting was divided into three tiers that illustrated the scene from different perspectives. These landscapes pioneered concepts that became important in other Zen art including the symbolic use of empty space and emphasis on rocks and trees, which eventually became significant metaphors.

Japanese monks who traveled in China brought Zen painting home in the thirteenth century. Sesshu Toyo (1414–81) reinvented the form so that it reflected Zen precepts in its veneration of nature's beauty. He inspired a number of other artists who worked for the next 150 years.

Gardening

Zen gardens were also inspired by Chinese models created during the Sung dynasty. The use of rocks, trees, sand, and water were replications of Ashikaga ink landscapes. The idea of depicting a garden as a three-dimensional painting inspired the development of perspective and abstraction approximately the same time as Ucello (1397–1495) was doing similar work with painting in Italy.

The Zen garden was designed, like a painting, for viewing with the hope the emotional reaction of the viewer would inspire greater awareness. Excellent examples from the

thirteenth and fourteenth centuries are in Kyoto. War and poverty in the fifteenth century inspired the creation of stark stone gardens called *kare sansu*. These monochromatic gardens were specifically designed for meditation. They anticipated several art techniques by centuries including the abstract expressionist 'symbolic arrangement of mass and space.'

Haiku

Haiku is a tightly structured poetry format that requires the use of exactly 17 syllables. The poems are written in time to the seasons and often encompass themes about nature. Created in the fourteenth century, haiku was popularized by the Zen monk Basho (1643–94). Haikus represent Zen thinking in their absolute absorption in the moment, offering a direct clear unmistakable experience without reference to anything else.

With every gust of wind,
The butterfly changes its place
On the willow

The best haikus are those which arise from the tension between the rigidity of the form and the depth of the poetic feeling.

Other Arts

The No drama, developed in the thirteenth century, used masks, dances and poetry to explore emotional experience. However, because there is no story and very little movement, most untrained Westerners have difficulty appreciating the plays. Like other Zen arts, the purpose is to inspire a profound emotional response. The Japanese puppet theater was also impacted by Zen. Zen was used to train the samurai in swordsmanship and archery. The Zen archer practiced breathing until it was second nature and the arrow could be released without thought. Intense concentration allowed Zen archers to attain phenomenal accuracy. A Zen mind-set helped warriors overcome fear and respond automatically and unconsciously with deadly accuracy during battles. In 1281, the samurai defeated Kubla Khan's army of more than 100 000 men. Zen also influenced the creation and training in martial arts such as kung fu, aikido, and judo.

In business, Zen influenced the design and development of products, the structure of companies and the way business decisions were made. Onda, a Japanese creativity researcher, stated that, compared to Westerners, the Japanese are more tolerant of ambiguity but not as logical. Intuitive thinking is more common, which may be partially based on meditation.

Psychology

Dr Shoma Morita developed Morita therapy in Japan in 1917. Fumitaka Noda noted that:

Drawing from Zen Buddhism, Morita therapy essentially helps people accept their destiny. In addition, the way people and traditional healers coexist reveals uniquely Japanese ambiguity and wisdom for accepting life as it is (2009:167)

The original method was focused on behavior change in clients with a variety of anxieties.

Naikan (which means inner looking in Japanese) takes place at a number of centers around Japan where patients stay for a week which is similar to the structure of Buddhist retreats. David Ryback, Akira Ikemi, Toru Kuno, and Yoshihiko Miki stated:

The *Naikan-sha* (client) is invited to meditate from 6 in the morning until 9 in the evening (meal and bathroom breaks excepted) in a comfortably seated position focusing on problematic interactions with significant others, taken in life-long chronological order – parents, siblings, spouse, and so on. (2001:133)

Specific themes focusing on relationships are selected and then short face-to-face meetings occur every hour or two. This format of brief highly focused meetings is what a Zen roshi (teacher) might do.

Hakoniwa is a therapy used in Japan which resembles Sand-play in the West. Zen gardens are designed to invoke both a sense of beauty and peaceful spirituality. During the session a miniature Zen garden is available where:

Clients work with sand and a variety of figurines and objects ... to construct gardens that reflect their personal worlds. (Carolyn Zerbe Enns and Makiko Kasai, 2003:93)

Renku is group therapy that directly uses the creative process in a format reminiscent of haiku. Participants each write a short verse:

The challenge of each individual is to render the previous stanza as deeply understood as if one were in the person of the author of that stanza, with both conscious as well as unconscious spheres of knowing. (Ryback et al., 2001:132)

The goal is to increase empathy and create a sense of group harmony.

Zen in the West

After the Second World War II, teachers from Japan moved to the United States and Europe establishing Zen centers in major cities and mountain retreats.

Beat Zen

Beat Zen was embraced in the 1950s by some writers and musicians who felt they were rebelling against American conformity. Alan Ginsberg's poems reached a wide audience, while Jack Kerouac wrote popular semiautobiographical novels such as *The Dharma Bums*.

John Cage developed a form of 'music' that used multiple tape recorders and wrote a piano recital where the pianist did not play a note, but a page turner still turned the pages. Drugs, especially marijuana, were identified with beat Zen enthusiasts. Alan Watts felt Kerouac "confused 'anything goes' at the existential level with 'anything goes' on the artistic and social levels." The social responsibility inherent in Zen Buddhism was forgotten.

Physiology

Meditation, mental exercises (koans), and skill training have been sources of interest for researchers in neurology and biology. Alpha biofeedback training may have originated with electroencephalogram (EEG) monitoring of Zen and Yoga practitioners who claimed that meditation may create a unique form of consciousness. Researchers found that zazen, when practiced by Monks, created slower breathing patterns and more muscle relaxation.

In 2009, Alberto Chiesa summarized key points after reviewing the literature including the finding that increased theta activity in advanced meditators helped relax various regions of the brain as well as reducing stress and lowering blood pressure. He added that:

Zen meditation practice could protect from cognitive decline usually associated with age and enhance antioxidant activity. (p. 585)

There may be similarities between meditation and the flow state in terms of total absorption.

A small study of musicians indicated that even a brief period of meditating may help reduce performance anxiety. However, there is still a great deal of research needed to understand the potential for positive interaction between Zen meditation and the arts.

Psychology

Zen has been advocated by a number of psychologists as a valuable tool that can complement traditional therapy. Modern interpretations of this include relaxation exercises, hypnosis, biofeedback, and openness to experience

Carl Jung admired Zen, but felt the states achieved sometimes had delusional elements. Like most Western psychologists, Jung believed in the concept of the self, which could never really know the collective unconscious. This viewpoint contrasted sharply with Buddhist practice, in which the experience of satori awakened and absorbed the unknown self into a world beyond human consciousness. Some theorists criticized the use of Zen in therapy. It has been suggested that Zen's fixation on enlightenment sometimes caused psychological problems, and that Morita-therapy was inappropriate for patients in the West because of its cultural dependence.

Other psychologists felt Zen could help reduce the ego, expand consciousness, and promote self-integration. It was thought that the sudden enlightenment and gradual training in Zen practice were comparable with 'insight' and 'working through' in psychology. The concept of personal growth inherent in Zen is a cornerstone of psychotherapy, especially notable in the work of Abraham Maslow and Carl Rogers. It was proposed that the psychotherapist could be compared to a Zen martial arts teacher in terms of developing specific teaching techniques and strategies for each client. Albert Ellis suggested that Zen could be integrated with rational-emotive therapy.

Morita-therapy, Naiken, and Hakoniwa have all been adapted in the West with some success. In the last 20 years, a number of American psychologists have written books and articles with their own recommendation for combining Zen and psychology.

Creativity Research

Investigation into creativity confirms the inherent worth of aspects of Zen training. Some researchers have proposed that there exists a similarity between solving koans and the creative problem-solving model of preparation, incubation, illumination, and evaluation. After preparation and incubation, a solution to a koan or a problem comes suddenly and unexpectedly. Satori is similar to the 'Aha' moment in creativity. Then the viability of the solution must be evaluated.

A few studies indicate creativity may be facilitated in sitting meditation by freeing perceptions. Other researchers identified a satiation effect, which resulted from focusing on a picture or words with intense concentration. Eventually previous meaning dissolved, which opened the possibility for new perspectives. Creative people have described a similar fixation on a specific melody when composing or a specific object when painting.

This process appears to break down previous belief systems, inhibiting cognition in favor of perception, in the same way that a Zen student must go through deconstruction of his or her belief system before arriving at enlightenment and a true understanding of the world. It is a shift in paradigms that links creativity and Zen.

The evidence that expertise takes ten years to achieve suggests that the slow learning mentor-student relationship practiced by Zen teachers may be more effective in the long run than some Western techniques. Flow, defined as the feeling of an almost automatic, effortless, yet highly focused state of consciousness, is similar to descriptions of Zen creativity.

Another aspect of Zen that could have application in creativity research is based on the concept of Beginners Mind (Shoshun). Shyunryu Suzuki explained this term in relation to meditation: "In the beginners mind there are many possibilities, but in the experts there are few" (p. 2, ND). The concept is consistent with the openness which researchers have proven is a personality characteristic of eminent creators. This openness is part of the novice effect in which an insight usually occurs within the first ten years of an individual entering a field (Robert Root-Bernstein).

Kuhn's concept of Paradigm Shifts could be considered an example of Beginner's Mind – an historian approaching science from a different angle than working scientists. The concept of Beginner's Mind has potential implications for important areas of creativity such as Problem Finding and Discovery.

Business and Sports

Zen training and ideas about creativity are working their way into mainstream thinking in Western society. The American business community has been exposed to some Zen principles since the 1970s and 1980s when Japanese businesses were thriving and American companies were struggling. Writers, consultants, and teachers gave advice about creative management using Zen principles, while others stressed meditation as a way to relieve stress. Nike had great success using the Zen-tinged slogan 'Just do it.' A movement toward spirituality in business led to further interest in Zen within the corporate world.

Books about Zen and using Zen have multiplied with training advice and application for a number of fields including

education, writing, career planning, guitar, and even stand-up comedy. Peter Matthiessen, a Zen practitioner for many years wrote about his search for inner peace in *The Snow Leopard*, which won the National Book Award in 1979.

As vegetarian diets increased in popularity, some Zen cook-books have cracked the marketplace. In sports, Phil Jackson used Zen principles to coach his teams to more NBA titles than any coach in history.

Tiger Woods is a Buddhist so now the Zen of Golf has joined The Zen of Tennis on the bookshelf. And let's not forget Zen and the Art of Windsurfing.

Conclusions

Zen has influenced both the concept and execution of many different areas involving creativity, especially in Japan. The key aspects that Zen affected include the following:

1. The training for professions, which in many ways interacted and reinforced Zen principles. Each type of training became known as a way to enlightenment. A mentor–master teacher worked with students to make routine aspects automatic and as free of ego as possible. Once the ego was minimized, the mind and body were free so creativity could become natural and spontaneous.
2. An element of deliberate incompleteness that required the audience to use their own life experience to participate in the creative process. The viewer is part of the picture. Zen art is designed to be an experience grasped as a whole, not intellectually analyzed.
3. An appreciation of asymmetry and 'happy accidents' that produced distinctive products. The term *wabi* is used to describe the nobility of simplicity and rough edges of Zen products.
4. Increasing awareness and understanding by altering perceptions and forcing the mind to stretch.
5. Emphasis on the nonverbal with only a minimum of words even in haiku and No drama.

Zen art has touched upon almost every aspect of Japanese life and its presence is still felt today. Sensitivity to nature, the awareness of beauty, and the attention to the aesthetic details in life inherent in Japanese culture are a direct legacy of Zen creativity.

Appendix I: Chronology of Events and Significant Ideas and Works on Creativity

M A Runco, University of Georgia, Athens, GA, USA

© 2011 Elsevier Inc. All rights reserved.

1859	Sir Francis Galton, first cousin to Charles Darwin, published <i>Hereditary Genius</i> .	1950	Guilford published his seminal article, "Creativity," based on his Presidential Address to the American Psychological Association.
1870	Galton's <i>British Men of Science</i> appears.	1950	Morris I. Stein founded the Center for the Study of Creativity and Mental Health. It was attached to the Psychology Department of the University of Chicago.
1876/1958	Charles Darwin's <i>Autobiography</i> . Howard Gruber, who refined biographical methods for the study of creative persons, claimed that Darwin's <i>Autobiography</i> is "one of the first and maybe the best autobiographies of a creator."	1952	Anne Roe's <i>The Making of a Scientist</i> is published.
1881	Cesare Lombroso, <i>The Man of Genius</i> .	1952	Frank Barron and G. S. Welsh publish the "Figure Preference Test" (later the "Barron-Welsh Art Scale").
1901	Alfred Binet, author of the first test of mental ability (later revised as the Stanford Binet IQ test) publishes "L'observateur et l'imagination" ["Imagination and the Observer"].	1952	Brewster Ghiselin's edited, <i>The Creative Process</i> .
1908	Freud published <i>Creative Writers and Daydreaming</i> .	1952	Kris describes "regression in the service of the ego" in <i>Psychoanalytic Explorations in Art</i> .
1910	Freud published <i>Leonardo da Vinci and a Memory of His Childhood</i> .	1957	Sputnik launched, drawing attention to the need for more emphasis on science, technology, and creativity.
1913	Henri Poincaré's <i>Science and Method</i> was published. It contained very influential essays and his famous insight about Fuchsian functions. [His <i>Science and Hypothesis</i> was published in 1905.]	1958	Symposium organized by H. Gruber, M. Wertheimer, and G. Terrell, published in 1962 as <i>Contemporary Approaches to Creative Thinking</i> .
1917	Wolfgang Köhler, <i>Mentality of the Apes</i> . Various demonstrations of insights.	1958	Kubie's <i>Neurotic Distortion of the Creative Process</i> is published.
1925	Louis Terman publishes the first volume from his classic longitudinal study, <i>Genetic Studies of Genius</i> .	1958	Frank Barron's "The Psychology of the Imagination" appears in <i>Scientific American</i> .
1926	Graham Wallas presents the seminal four-stage model of the creative process, with the preparation, incubation, illumination, and verification stages.	1959	Maslow tied creativity to self-actualization in "Creativity in Self-Actualizing People." He later concludes that creativity and self-actualization may be inextricable.
1926	Catherine Cox publishes <i>Genetic Studies of Genius. Vol. 2: The Early Mental Traits of Three Hundred Geniuses</i> .	1960	Donald Campbell's "Blind Variation and Selective Retention" appears in <i>Psychological Bulletin</i> .
1935/1945	Karl Duncker, <i>On Problem Solving</i> . [Reports the famous radiation problem.]	1962	Donald MacKinnon's "Nature and Nurture of Creative Talent" is released in the <i>American Psychologist</i> .
1937	Catherine Patrick's article, "Creative Thought in Artists," appears in the <i>Journal of Psychology</i> . [Her "Creative Thought in Poets" appeared in 1935.]	1962	Goertzel and Goertzel published <i>Cradles of Eminence</i> .
1942	Leta Stetter Hollingworth, <i>Children above 180 IQ</i> .	1962	Thomas Kuhn presents seminal ideas about paradigms in <i>The Structure of Scientific Revolutions</i> (Chicago University Press).
1945	Max Wertheimer, <i>Productive Thinking</i> .	1962	Jerome Bruner defines creativity as "effective surprise" in his article, "The Conditions of Creativity."
1945	Jacques Hadamard, <i>The Psychology of Invention in the Mathematical Field</i> . Probably the first questionnaire study of mathematicians and an interesting account of Poincaré's famous insight.	1962	Mednick's theory of remote associates is presented in his article, "The Associative Basis of the Creative Process" (<i>Psychological Bulletin</i>).
1946	Henri Bergson's <i>The Creative Mind</i> is published.	1962	Getzels and Jackson's <i>Creativity and Intelligence: Explorations with Gifted Students</i> stirs debate over the distinction between creativity and traditional intelligence.
1946	Division 10 (Psychology and the Arts) is one of the founding divisions of the American Psychological Association.	1963	Calvin Taylor and Frank Barron publish <i>Scientific Creativity</i> (proceedings from the Utah Conferences).
1949	Institute for Personality Assessment and Research founded (Berkeley, CA). Barron, MacKinnon, Helson, and many others would conduct significant research on creativity at IPAR.	1963	Osborn's <i>Applied Imagination</i> is published.

- 1964 Roger Sperry reports significant differences between the two hemispheres of “split brain” patients (*Scientific American*).
- 1964 Arthur Koestler introduces “bisociation” in his book, *The Act of Creation*.
- 1965 Michael Wallach and Nathan Kogan published *Modes of Thinking in Young Children*—a huge step for assessment with divergent thinking tests and clarification of the relationship between creativity and traditional intelligence.
- 1966 E. Paul Torrance publishes the “Torrance Tests of Creative Thinking” (which were previously the “Minnesota Tests of Creative Thinking”).
- 1967 The first issue of the *Journal of Creative Behavior* appears.
- 1969 Wallach and Wing’s *The Talented Student* appears.
- 1969 Rudolph Arnheim’s *Visual Thinking* is published.
- 1970 P. E. Vernon’s collection, *Creativity*, is published by Penguin.
- 1972 Getzels and Csikszentmihalyi describe the value of problem finding for artists and publish *The Creative Vision*.
- 1972 Nicholls publishes “Creativity in the Person Who Will Never Produce Anything Original or Useful” in the *American Psychologist*.
- 1973 Khatena and Torrance’s *Thinking Creatively with Sounds & Images* (rev. 1998, Scholastic Testing Service).
- 1974 Morris Stein publishes two volumes of *Stimulating Creativity*.
- 1974 Howard Gruber’s *Darwin on Man* demonstrates the value of case studies and applies systems thinking to the topic.
- 1974 E. Paul Torrance directed the first Future Problem Solving activities in Athens, GA, USA.
- 1975 Robert Albert’s “Behavioral Definition of Genius” published in the *American Psychologist*.
- 1975 Dean Keith Simonton revitalizes the historicist approach to the study of exceptional achievement (*Journal of Personality and Social Psychology*).
- 1977 Harriet Zuckerman’s *Scientific Elite* appears.
- 1983 Howard Gardner published *Frames of Mind*. It contains the most convincing argument to date for the delineation of domains.
- 1988 The *Creativity Research Journal* is founded.
- 1990 The U.S. Patent and Trademark Office publishes their *Inventive Thinking Curriculum Project*.
- 1990 Creativity Symposium held at Pitzer College in Claremont, CA (proceedings published in M. A. Runco and R. S. Albert’s *Theories of Creativity*).
- 1990 International Working Creativity Research Conference, Center for Creative Studies, State University College of New York at Buffalo (proceedings published in Isaksen et al. *Understanding and Recognizing Creativity*).
- 1990 The first Gustav Theodor Fechner Award was given to Rudolf Arnheim by Division 10 of the American Psychological Association for Outstanding Achievement in Psychology and the Arts. (Since 1990 it has been given annually but called the Rudolf Arnheim Award.)
- 1992 IBM and PBS Television develop and televise “The Creative Spirit.”
- 1993 Doris Wallace and Howard Gruber edit a special issue of the *Creativity Research Journal* which explicates the need for research on “Creativity in the Moral Domain.”
- 1993 Nobel laureates describe their work in a symposium on scientific creativity at the Royal Society of Medicine, published in a special issue of the *Creativity Research Journal*.
- 1999 The *Encyclopedia of Creativity* is published by Academic Press.
- 2005 *Psychology of Aesthetics, Creativity, and the Arts* becomes an American Psychological Association Journal.
- 2006 Sir Ken Robinson’s Ted talk *Do Schools Kill Creativity?* received two million views on YouTube by 2011.
- 2006 *Thinking Skills and Creativity* is a new journal published by Elsevier.
- 2006 *Journal of Creativity in Mental Health* debuts as a Routledge publication.
- 2007 Saybrook University offers a Masters of Psychology with an Emphasis on Creativity Studies in addition to a Creativity Studies Certificate.
- 2008 Mark Runco selected at the first E. Paul Torrance Professor at the University of Georgia, Athens, GA, USA.
- 2010 Poll by IBM of over 1,500 corporate and public sector CEO’s and public leaders in 60 countries and 33 industries indicated that creativity was considered the most important leadership quality.
- 2011 TED talks related to creativity given by Mihaly Csikszentmihalyi, Amy Tan and Elizabeth Gilbert receive over 100,000 views on YouTube.

- XIX. Puns, Similes, and Linguistic Creativity

This appendix reviews some of the TESTS used to assess creativity. Psychometric issues about many of these tests are given in the Mental Measurements Yearbooks, Tests in Print, and various texts on testing. Some tests listed herein were not developed for creativity but either have been adapted to that end (e.g., Tangrams) or have several scales, one of which is directly relevant to creativity or originality (e.g., the Adjective Check List and the California Psychological Inventory).

Creativity is often assessed with other techniques, such as interviews, open-ended surveys, or a tally of products. Sometimes in the research, nominations are used rather than an instrument with a score. This appendix covers only tests, inventories, and rating scales. It does not cover all assessments. It is only a partial list of some of the major tests. Some tests and assessments are difficult to categorize. Several of them target more than one thing (e.g., personality traits, attitudes, and experiences) and others have a name that may not be the best descriptor of what is actually assessed.

Some tests and assessments are difficult to categorize. Several of them target more than one thing (e.g., personality traits, attitudes, and experiences) and others have a name that may not be the best descriptor of what is actually assessed.

I. Biographical Inventories

Alpha Biographical Inventory of Creativity.

(1968). The Institute for Behavioral Research in Creativity. Salt Lake City, UT.

Biographical Inventory of Creativity: Art and Writing Scales for females; Art-Writing and Math-Science for males.

Schaefer CE (1970) San Diego, CA: Educational and Industrial Testing Service.

II. Personality

Adjective Check List (ACL). Various scales have been developed to identify creativity and at least four others are relevant (i.e., intelligence-origence).

Gough H and Heilbrun AB (1983) USA: Consulting Psychologists Press.

See also Domino G (1994) *Creativity Research Journal* 7: 21–34.

California Psychological Inventory (CPI). The CPI is now routinely scored for the Creative Temperament Scale. An older Creative Personality index was scored from the standard scales and an Empathy scale ($\text{Creativity} = 65.96 + .63\text{Cs} - .34\text{Sy} - .37\text{Gi} - 1.15\text{Cm} + .61\text{Em}$).

Gough H (1975) Palo Alto, CA: Consulting Psychologists Press.

Sixteen Personality Factor Questionnaire. The Cattell 16PF has a creativity index based on a regression formula.

Cattell RB (1986) USA: Institute for Personality and Ability Testing.

The Myers-Briggs Type Indicator includes Intuitive as one of four primary domains.

Briggs MI and Briggs K (1985) Palo Alto, CA: Consulting Psychologists Press.

The NEO Personality Inventory has an openness scale which is reportedly correlated with creativity.

Costa P and McCrae RR (1985) Odessa, FL: Psychological Assessment Resources, Inc.

Overexcitability Questionnaire-II (OEQ II): 50 items, Likert scale, ten items in each of five forms of over-excitability.

Falk RF, Lind S, Miller NB, Piechowski M, and Silverman LK (1999) Institute for study of advanced development.

What Kind of Person Are You? is a subtest of the Khatena-Torrance Creative Perception Inventory.

Khatena J and Torrance EP (1976) Bensenville, IL: Scholastic Testing Service.

Creative Behavior Disposition Scale.

Taylor IA and Fish RA (1979) The creative disposition scale: A Canadian validation. *Canadian Journal of Behavior Science* 11: 95–97.

The Creative Characteristics Rating Scale is one part of the Rating the Behavioral Characteristics of Superior Students (Renzulli, Smith, White, Callahan, and Hartman, 1976). Like the *How Do You Think Test?* It inquires about tendencies and characteristics, as well as engagement in activities that probably require creative talents. It is therefore a hybrid and covers activities as well as traits.

A Chinese version was described by Chan DW and Zhao Y (2010) in "The Relationship Between Drawing Skill and Artistic Creativity: Do Age and Artistic Involvement Make a Difference?", *Creativity Research Journal*, 22(1), 27–36.

Students' Creative Self-efficacy Questionnaire (Huang and Lin, *Creativity Research Journal*, 2005).

Creative Personal Identity (Jaussi KS, Randel AE, and Dionne SD (in press). I am, I think I can, and I do: The role of personal identity, self-efficacy, and cross-application of experiences in creativity at work. *Creativity Research Journal*.

MMPI Creativity Scale. See Nassif C and Quevillon R (2008). The Development of a Preliminary Creativity Scale for the MMPI-2: The C Scale. *Creativity Research Journal*, 20(1), 13–20.

III. Rating Instruments and Socially Valid Measures

Students' Self-Evaluation of Creativity.

Miller HB and Sawyers JK (1989) A comparison of self and teachers' ratings of creativity in fifth grade children. *Creative Child and Adult Quarterly* 14: 179–185, 229–238.

The Parental Evaluation of Children's Creativity—Revised.

Runco MA, Johnson D, and Bear P (1993) Parents' and teachers' implicit theories of children's creativity. *Child Study Journal* 23: 91–113.

Preschool and Kindergarten Interest Descriptor.

Rimm SB (1983) Watertown, WI: Educational Assessment Service, Inc.

Teacher's Evaluation of Student's Creativity.

Runco MA (1984) *Perceptual and Motor Skills* 59: 711–717. Scales for Rating the Behavioral Characteristics of Superior Students.

Renzulli JS, Smith LH, White AJ, Callahan CM, and Hartman RK (1976) Scales for rating the behavioral characteristics of superior students. Mansfield Center, CT: Creative Learning Press.

Co-worker and subordinate rating scales were used by Jaussi KS, Randel AE, and Dionne SD (in press). I am, I think I can, and I do: The role of personal identity, self-efficacy, and cross-application of experiences in creativity at work. *Creativity Research Journal*.

IV. Styles

Kirton Adaptation-Innovation Inventory (KAI).

Adaptors and Innovators: A Description and Measure. (1976). *Journal of Applied Psychology* 61: 622–629.

The Creativity Styles Questionnaire-Revised (CSQ-R) assesses seven styles of creativity, with style defined in terms of personal strategies and beliefs about being creative. The styles focus on *Belief in Unconscious Processes, Use of Techniques, Use of Other People, Final Product Orientation, Environmental Control and Behavioral Self-Regulation, Superstition, and Use of the Senses*. See Kumar, Kemmler, and Holman (1997), *Creativity Research Journal*, 10, 51–58.

Kaufmann and Martinsen's Assimilator/Explorer measure of styles.

Martinsen O (1993) Insight problems revisited: The influence of cognitive styles and experience on creative problem solving. *Creativity Research Journal* 6: 435–447.

Your Style of Learning and Thinking

Torrance EP (1977) *The Gifted Child Quarterly* 21(4): 563–573.

Creative Problem Solving Inventory.

Basadur M, Wakabayashi M, and Graen GB (1990) *Creativity Research Journal* 3: 22–32.

V. Divergent and Associative Thinking and Problem Solving

Divergent and Associative Thinking Tests

For preschool children: Multidimensional Stimulus Fluency Measure.

Broberg G and Moran J, III (1988) *Creativity Research Journal* 1: 115–121.

Guilford JP (1960) relied on Consequences, Alternate Uses, and Plot Titles. He also developed Names for Stories (1971), Plot Titles (1962), Possible Jobs (1963), Seeing Problems (1971).

Guilford's approach and tests are described in his book.

Guilford JP (1968) *Creativity, Intelligence, and Their Educational Implications*. San Diego, CA: EDITS/Robert Knapp. Meeker and Meeker (1975) further developed Guilford's ideas about the structure of intellect as part of their test battery for school children.

Meeker M (1987) Meeker creativity rating scale. Vida, OR: SOI Systems.

Wallach and Kogan (1965) used two visual tests (Pattern Meanings and Line Meanings) and three verbal tests (Uses, Instances, and Similarities).

Wallach MA and Kogan N (1965) *Modes of Thinking in Young Children: A Study of the Creativity–Intelligence Distinction*. New York: Holt, Rinehart and Winston.

Multiple Choice Test of Divergent Thinking. Abedi-Schumaker Creativity Test.

Auzmendi E, Villa A, and Abedi J (1996) *Creativity Research Journal* 9: 89–95.

Remote Associates Test (Mednick, 1967).

Word Association Test. Gough HG (1976). Studying creativity by means of word association tests. *Journal of Applied Psychology*, 61, 348–353.

Functionally Remote Associates Test (Worthen and Clark, 1971 *Journal of Educational Measurement*, 8, 113–123).

Runco MA developed divergent thinking tasks to examine "problem generation," one aspect of problem finding, and "real-world" tasks that were predictive of problem solving in the natural environment.

See Runco's 1994 book *Problem Finding, Problem Solving, and Creativity*, Norwood, NJ: Ablex.

Test for Creative Thinking-Drawing Production.

Urban KK (1991) On the development of creativity in children. *Creativity Research Journal* 4: 177–191.

Torrance Tests of Creative Thinking

(e.g., Product Improvement, Ask and Guess, Just Suppose).

Thinking Creatively with Sounds and Word, Sounds and Images, Onomatopoeia and Images.

Torrance EP, Khatena J, and Cunningham BF (1973) Personnel Press.

Thinking Creatively in Action and Movement

Torrance JP (1974) Georgia Studies.

Thinking Creatively About the Future

Torrance JP (1974).

Torrance Test of Imagination

Torrance JP (1959) Bureau of educational research, University of Minnesota.

Scores: The most common scores from divergent thinking tests are Fluency, Originality, and Flexibility. Guilford also used a remoteness score for Consequences; Runco developed an Appropriateness index; Torrance an elaboration index.

Formulating Hypotheses Test. Quantity and quality of ideas generated when formulating hypotheses, designing methods for measurement, solving problems involving the scientific method, and when evaluating research proposals.

Frederiksen N and Ward WC (1978) *Applied Psychology Measurement* 2(1): 1–24.

Remote Associates Test. Remote Associates Test: Examiners manual.

Mednick S (1967) Boston: Houghton Mifflin.

Functionally Remote Associates Test.

Worthen and Clark (1971) *Journal of Educational Measurement* 8: 113–123.

German version (Verbaler Kreativitätstest, VKT, Schoppe, 1975), with nine subtests, including uses and similarities, but also nicknames, “utopian situations,” and word-beginnings and -endings.

Cheung PC and Lau S (2010) Gender Differences in the Creativity of Hong Kong School Children: Comparison by using the New Electronic Wallach-Kogan Creativity Tests, *Creativity Research Journal*, 22(2), 194–199.

VI. Work and Educational Environment

The Creative Environment Scales: Work Environment Inventory.

Amabile TM, Gryskiewicz, and Nur D (1989) *Creativity Research Journal* 2: 231–253.

Creative Climate Questionnaire. Ekvall G and Ryhammar L (1999). The Creative Climate: Its Determinants and Effects at a Swedish University. *Creativity Research Journal*, 12, 303–310.

Climate for Creativity.

Torrance EP (1958) Bureau of Educational Research.

Classroom Climate Questionnaire.

Walberg and Anderson (1968) *Journal of Creative Behavior*.

Technical Audit for Creativity of Organizations.

Stein MI (1959) Amagansett, NY: Mews Press.

Epstein Creativity Competencies Inventory for Managers. Measures eight competencies that predict managers' ability to elicit creativity in others.

Epstein R (1998) InnoGen. West Chester, PA.

Jones Inventory of Blocks.

A self-report described in the *Creativity Research Journal* (1991), 4, 303–315.

Creativity Audit for Organizations.

Rickards' creativity audit measures self-report data on three levels: (1) local or team; (2) organizational; and (3) market environment.

Rickards T and Bessant J (1980) The creativity audit: Introduction of a new research measure in programs for facilitating organizational change, *R&D Management* 10(2): 67–75.

Climate for Creative Productivity Index, Witt and Beorkrem (1989) *Creativity Research Journal*, 2, 30–40.

Creative Environment Perceptions: A Questionnaire for Investigating Garden Variety Creativity (Mayfield and Mayfield, 2010, *Creativity Research Journal*, 22(2), 162–169.

VII. Competencies

The *Epstein Creativity Competencies Inventory for Individuals* assesses four competencies: capturing ideas, challenging tasks, broadening knowledge and skills, and surrounding and seeking new stimuli. See Epstein, Schmidt, and Warfel (2008), *Measuring and Training Creativity Competencies: Validation of a New Test*, *Creativity Research Journal*, 20, 7–12.

VIII. Aesthetic Sensitivity

Tests of Aesthetic Sensitivity.

Frois JP and Eysenck HJ (1995) The visual aesthetic sensitivity test applied to Portuguese children and fine art students. *Creativity Research Journal* 8: 277–284.

IX. Projective and Perception Measures

Creative Functioning Test.

Smith G, Carlsson I, and Andersson G (1989) *Creativity Research Journal* 2: 1–16.

Thematic Apperception Test (TAT). A projective measure often used in clinical assessments of personality. A blank card has been used to assess problem finding tendencies.

Murray H (1973) Psychological Corporation, San Antonio, TX.

(See also Eisenman R (1992) *Creativity Research Journal* 5: 175–181.)

Rorschach Psychodiagnostic Technique.

See Richter RH and Winter WD (1966) Holtzman inkblot correlates of creative potential. *Journal of Projective Techniques and Personality Assessment*, 30, 62–67.

Rawls JR and Boone JN (1967) Artistic creativity and Rorschach whole responses. *Journal of Projective Techniques and Personality Assessment*, 31, 18–22.

Rawls JR and Slack GK (1968) Artists versus non-artists: Rorschach determinants and creativity. *Journal of Projective Techniques and Personality Assessment*, 32, 233–237.

Synaesthesia Questionnaire.

Domino G (1989) *Creativity Research Journal* 2: 17–29.

Khatena Torrance Creative Perception Inventory. Contains two tests of Creative Self-Perceptions: What Kind of Person Are You? and Something about Myself.

Khatena J and Torrance EP (1998) Bensenville, IL: Scholastic Testing Service.

Physiognomic Cue Test.

Stein M (1974) Physiognomic cue test: Test and manual. Amagansett, NY: Mews Press. (See also Martindale in *Creativity Research Journal*; and Perez-Fabello and Campos (2011), Dissociative experiences and creativity in fine arts students, *Creativity Research Journal*, 23, 38–41.)

X. Intuition, Synaesthesia, and the Unconscious

Westcott (1966) developed a measure of intuition containing 20 analogy problems. See also Mumford et al. (2007) *Creativity Research Journal*.

Accumulated Cues Test. Bowers KS, Regehr G, Balthazard C, and Parker K (1990). Scores are calculated from the number of cues (and amount of data) a respondent requires before he or she produces an accurate hypotheses. The highest level of intuition is suggested when the respondent needs no cues.

Preconscious Activity Scale (Holland and Baird (1968) *Journal of Creative Behavior*, 2, 214–223).

Creative Functioning Test (Smith, Carlsson, and Andersson, (1989) *Creativity Research Journal*, 2, 1–16).

XI. Preferences and Attitudes

Barron Welsh Art Scale. (Originally the Figure Preference Test, 1949). Assumes that the preference for complexity is predictive of creative talent.

Welsh G and Barron F (1963). Palo Alto, CA: Consulting Psychologists Press.

Basadur's Attitude Measure. Originally a 14-item self-report, expanded in the 1996 *Creativity Research Journal*. The original version was scored for two scales measuring the preference for ideation and the tendency toward premature closure.

Basadur MS and Hausdorf PA (1996) Measuring divergent thinking attitudes related to creative problem solving and innovation management. *Creativity Research Journal* 9: 21–32.

How Do You Think test. A mix of achievements, attitudes, and opinions—with good predictive validity. For younger persons, the Group Inventory for Finding Interests (GIFFT) and the Group Inventory for Finding (creative) Talent (both Ed Assessment Service, Inc.)

Davis G (1975) *Journal of Creative Behavior*.

The Creative Attitude Survey. A creativity measure for 9–11 year old children, which assesses imagination, interest in art and writing, desire for novelty, and attraction to abstract and magical, e.g., I get bored easily.

Schaefer C and Bridges CI (1970) Development of a creative attitude scale for children. *Perceptual and Motor Skills* 31: 861–862.

The Personal Opinion Survey. Contains 30 item true-false items.

Eisenman R (1969) Components of creativity, verbal conditioning, and risk taking. *Perceptual and Motor Skills* 29: 687–700. What Kind of Person Are You?

Khatena J and Torrance EP (1976) Bensenville, IL: Scholastic Testing Service.

Eisenman's Preference for Polygons test

Eisenman R (1966) Perceived creativity, set, and preference for simple or complex shapes. *Perceptual and Motor Skills* 22: 111–114.

The *Obscure Figures Test*: Acker M and McReynolds P (1965) An instrument for measuring cognitive innovation. *Perceptual and Motor Skills*, 21, 815–821.

Visual Elaboration Scale. Campos A and Pérez MJ (1988). *Perceptual and Motor Skills*, 66, 411–414.

XII. Criterion Measures

Instruments in this category are typically thought to assess *actual* creative behavior rather than tendencies or the potential for creativity. Here is a sample of the better known instruments: Tel-Aviv Activities and Accomplishments Inventory.

Three forms: Primary, Adolescent, Adult.

Milgram R (1973, 1998) see her chapter in the book, *Theories of Creativity*, Hampton Press (in press).

Academic, Military, Work, and Leisure Activities sub-scales.

Creative Achievement Scale.

Ludwig A (1992) *Creativity Research Journal* 5: 109–124.

Lifetime Creativity Scales

Richards R, Kinney DK, and Benet M (1988) Developed at McLean Hospital, Belmont, MA and Harvard Medical School.

Richards R, Kinney DK, Benet M, and Merzel A (1988) Assessing everyday creativity: Characteristics of the lifetime creativity scales and validation with three large samples. *Journal of Personality and Social Psychology* 54: 476–485.

Runco Ideational Behavior Scale (RIBS) is a self report developed as a criterion measure specifically for divergent thinking tests. It is a behavior scale in that it attempts to assess actions and activities requiring ideation more than the ideational (cognitive) process. See Plucker JA, Runco MA and Lim W (2006). Predicting ideational behavior from divergent thinking and discretionary time on task. *Creativity Research Journal*, 18, 55–63.

Things Done on Your Own (Torrance, 1962) is a behavioral assessment of creativity that requires respondents to state how often they have engaged in a task outside of school, in language arts, science, social studies and art, e.g., Have you ever designed jewelry?

Statement of Past Creative Activities (Bull and Davis, 1982) asks respondents to list activities in which they have engaged and that are creative (e.g., I have put on a play).

XIII. Activity Checklists

Holland's checklists of extracurricular and academic activities. Extracurricular creative activity. Given in the book *The Talented Student*.

Wallach and Wing (1969) New York: Holt, Rinehart and Winston.

Quality and quantity of activities in seven domains.

Runco MA (1986) Divergent thinking and creative performance in gifted and nongifted children. *Educational and Psychology Measurements* 46: 375–384.

Runco's Ideational Behavior Scale (RIBS). Designed specifically as criterion for divergent thinking tests. The emphasis is on actual behavior involving ideas. Originally 93 items with Likert scale but a 23-item subscale is most reliable.

Runco MA (1992) *Divergent Thinking and Creative Ideation*. Hampton Press.

XIV. Creative Products

Tangrams.

Domino G (1980) Chinese tangrams as a technique to assess creativity. *Journal of Creative Behavior* 14: 204–213.

Creative Products Semantic Scale (CPSS) contains 55 bipolar adjective pairs, Likert Scale. Three factors are represented: Novelty, Resolution, and Synthesis.

Besemer S and O'Quin K (1989) The development, reliability, and validity of the revised creative product semantic scale. *Creative Research Journal* 2: 268–278.

XV. Domain-Specific Measures

Action Preference Test.

Alter J (1989) *Creativity Research Journal* 2: 184–195.

Manual for Evaluating Performance in Technical Personnel.

Stein MI (1961) Science Research Associates.

Musical Creativity Test (1971).

Musical Divergent Production test

Gorder W (1976) An investigation of divergent production abilities as constructed of musical ability. *Dissertation Abstracts International* 37: 171.

Measure of Creative Thinking in Music (version II)

Webster (1983).

Poetry Writing.

Kasof J (1997) *Creativity Research Journal* 10: 303–316.

Iowa Inventiveness Inventory.

Colangelo N, Kerr B, Hallowell K, Huesman R, and Gaeth J (1992) The Iowa inventiveness inventory: Toward a measure of mechanical inventiveness. *Creativity Research Journal* 5: 157–163.

Preconscious Activity Scale

Holland and Baird (1968) *Journal of Creative Behavior* 2: 214–223.

Pun Test.

Karlines (1967) *Journal of Psychology* 67: 335–340.

Barron Symbol Equivalents Test.

Barron F (1958) *Scientific American*; or (1996) *No rootless flower*. Cresskill, NJ: Hampton Press.

Barron Anagram Test.

Barron F (1958) *Scientific American*; or (1996) *No rootless flower*. Cresskill, NJ: Hampton Press.

Torrance EP (1970) *Thinking Creatively in Action and Movement*.

XVI. Art and Aesthetics

Clark's Drawing Abilities Test (CDAT; Clark and Zimmerman (2004); Chan and X (in press) *Creativity Research Journal*)

The *Drawing Activity Checklist* and the *Art-Related Activity Checklist* (Chan and Chan (2007) *Creativity Research Journal*) contain five yes/no questions concerning students' experience with and interest in drawing. Self report.

Frank Drawing Completion Test. Anastasi and Schaefer (1971) used it specifically as test of creative potential. *Journal of Genetic Psychology*, 119, 3–12.

Photo Essays. Dollinger used photo essays to assess creativity. Students are asked to take or at least identify 20 photographs which allow them to compose a photo essay, the theme of which is "who are you?". Dollinger rated these photo essays on a Likert scale with one representing unimaginative and commonplace, and five representing creative, aesthetic sensitivity, and self reflection. He reported two or three studies with convergent validation and interjudge coefficients ranging from 0.4 to 0.8. Alpha was 0.87.

Aesthetic Judgment Test (Bamossy, Johnston, and Parsons, 1985) has been revised. It asks for judgments and it promises to provide a basis for explaining differences in aesthetic judgment.

New Aesthetics Test (Lindauer et al., 1976).

Modal Imagery Test (Lindauer, 1977).

XVII. Play Scales

Affect in Play Scale. See Moore and Russ (2008) Follow-up of a Pretend Play Intervention: Effects on Play, Creativity, and Emotional Processes in Children. *Creativity Research Journal*, 20(4), 427–436.

The Adult Playfulness Scale. Glynn MA, and Webster J (1992) The adult playfulness scale: An initial assessment. *Psychological Reports*, 71: 83–103.

The Adult Playfulness Scale (Revised) (Glynn MA, and Webster J (1993) *Psychological Reports*, 72: 1023–1026).

XVIII. Emotional Creativity

The *Emotional Creativity Inventory* measures three facets of emotional creativity: Preparation, Novelty, and Effectiveness/Authenticity. See Gutbezahl and Averill (1996) *Creativity Research Journal*, 9, 327–337.

XIX. Puns, Similes, and Linguistic Creativity

The Similes Test (Schaefer C (1969) *Similes manual*, NYC Center for Urban Education).

The *Language Preference Report* assesses the affinity for figurative language. See Yarbrough D (1991) *Creativity Research Journal*, 4, 317–335.

Pun test (Karlines (1967), *Journal of Psychology*, 67, 335–340).

INDEX

Notes

All entries refer to creativity unless otherwise mentioned. Index entries under 'creativity' have been minimized and readers are advised to seek more specific topics.

Cross-reference terms in italics are general cross-references, or refer to subentry terms within the main entry (the main entry is not repeated to save space). Readers are also advised to refer to cross-references within each article – not all of these cross-references have been included in the index cross-references.

The index is arranged in set-out style with a maximum of three levels of heading. Major discussion of a subject is indicated by bold page numbers. Page numbers suffixed by T and F refer to Tables and Figures respectively. *vs.* indicates a comparison.

This index is in word-by-word order, whereby hyphens and spaces within index headings are given value in the alphabetization. For example, 'self-worth' is alphabetized before 'selfish genes'. Prefixes and terms in parentheses are excluded from the initial alphabetization.

Where index subentries and sub-subentries pertaining to a subject have the same page number, they have been listed to indicate the comprehensiveness of the text.

Abbreviations

DFI – Domain, field and individual (model)

RAT – Remote associates test

SNP – Single nucleotide polymorphism

SOI – Structure of the intellect mode

4'33" (by John Cage) 1:54

 why made 1:392–393
- DISCOVER program 2:65–66, 2:67
- discretion
 definition 1:456, 2:220
 as part of personal creativity 2:222
- discriminant stimulus 1:135
- discriminant validity *see* validity
- discrimination against creativity 2:507
- disequilibrium 1:384, 2:418
 person in state of 2:416
- disinhibition, creativity and 1:30
- disintegration, positive, theory of 2:202
- Disney, Walt 1:261
- disorder (lack of order)
 order relationship 2:419, 2:421
 preference for by creative people 2:418
 role, self-organization and 2:421
- disorderliness, creative students 2:440
- dispassion 2:364, 2:366
- displacement of concepts 1:385–386
- dispositional factor 1:96
 situational factor *vs* 1:96–99
- Dispositional Flow Scale-2 (DFS-2) 1:526–527
- dispositions, definition 1:208
- disruptive innovation 1:351, 1:352
- dissatisfaction, as creativity stimulus 2:143
- dissertations on creativity 1:96–97
- dissipative systems 1:183
 edge of chaos and 1:186, 1:188
- dissociation, definition 1:1
- 'distant-engagement' 2:300
- distinctiveness 1:96
 attributions and 1:97, 1:98
- 'distributed creativity' (Sawyer and DeZutter) 2:471
- distribution of creativity 1:308, 1:308f, 1:397–399
 diffusion of creative ideas 1:398–399
 learning, expertise and creativity 1:399
 motivation and creative performance 1:397–398
 multiplicative theories of creativity 1:398
 positive skew 1:397, 1:398f
 statistical 1:397
 Zipf 1:397, 1:398f
- divergence, principle of (Darwin's) 1:e26
- divergent feeling, test 2:308
- divergent processes 1:351
 in problem finding 2:251
- 'divergent production' abilities 1:470
- divergent thinking 1:61, 1:167–168, 1:274, 1:280, 1:293, 1:400–403, 2:326
 Alternate Uses Test and 1:167, 1:400–401
 associations generated 1:450
 asynchronicity at personal level 1:73
 attitudes towards 1:93
 bilingual children 1:337
 birth order and 1:154
 as class of thinking skills 1:407

- motivation (*Continued*)
 conformity reducing 1:242
 for creative performance 1:397–398
 for creativity 1:143, 1:365, 2:63–64, 2:303, 2:342, 2:345–346
 janusian/homospacial processes 2:7
 deficiency needs and growth 2:149
 definition 2:147
 in model of creativity 1:226, 2:345–346
 for discoveries 1:392
 for domain activity, enjoyment 1:491–492
 dynamically changing 1:365
 ego-involved 1:241, 1:242
 essential to creativity 1:229
 Evolving Systems Approach and 1:478–479
 external factors/reactions 1:266
 enhancement of creativity 1:458
 groups/teams 1:578
 less creative people 2:225–226
 extrinsic 1:478, 2:346, 2:438
 decreasing creativity and 2:150, 2:438
 definition 1:476, 2:147, 2:345
 enhancing creativity 1:458, 2:150
 fostering of creativity and 2:438
 rewards increasing 2:149, 2:313–314, 2:316
 teams 2:447–448
 Work Preference Inventory and 2:148
 flow experience and 1:522
 fostering of creativity 2:436, 2:438
 in group creativity 1:577
 for innovation 1:660
 inspiration's 2:151–152, 2:368
 intrinsic 1:208, 1:265–266, 1:362, 1:365, 1:478, 2:438
 creative people *vs* general population 2:148
 curiosity as 1:424
 definition 1:450, 1:476, 1:575, 2:147, 2:200, 2:345, 2:486
 driving force for flow 1:525, 2:148–149
 emotion and affect 2:148–149
see also affect (mood); emotion(s)
 employees and creativity 2:149, 2:200
 factors involved 2:345–346
 in families 1:507
 groups/teams 1:577–578, 2:447–448
 Haydn and 1:584
 idealism as 1:424
 increased creativity 1:452, 1:457–458, 2:346, 2:486
 personal choice involvement 2:346
 Piaget and 1:75
 positive affect associated 1:452
 principle 2:150
 reduced with external rewards 2:346
 risk taking affected by 2:321
 social environment and 2:150–151
 support for 2:150
 trait in autonomy 2:225–226
 Work Preference Inventory and 2:148
 for invention 1:695
 mastery goals 2:503
 obsessive passion 2:149
 optimal level of challenges 2:149
 organizational factors affecting 1:208, 2:149
 impediments 1:209
 patterns of 2:438
 performance goals 2:503
 positive affect *see* affect (mood)
 prerequisites for creativity 2:438
 problem finding 2:251
 reinforcers and operant conditioning 2:149–150
 resolution of tension and 1:452
 rewards increasing 2:149, 2:313–314, 2:316
 sports 2:377
 support/encouragement, work spaces providing 1:268–269
 task-involved 1:241
 teaching of creativity and 2:438–439
 teams 1:577–578, 2:447–448
 traits, scientific creativity and 1:299
 underachievement due to 2:503
 of writers 2:530
- motivational synergy
 definition 2:147
 theory 2:150
 motivational systems, broad 1:450
 motives (creative), classes ('triad' model) 1:365
 motives (unconscious), Freud's views 1:e36
 motivic improvisation 1:647, 1:650
 motifs (licks) 1:650
 motor actions
 approach-related *see* approach-related motor actions
 avoidance-related *see* avoidance-related motor actions
 mountain bikes 1:262
 movie awards 1:109–110, 1:510–511
 categories 1:109–110
 clusters and correlates 1:110
see also film(s), awards
 movies *see* film(s)
 Mozart, Leopold 2:169
 Mozart, Wolfgang Amadeus
 abilities, nature *vs* nurture debate 2:169
 age for early compositions 2:48
 Beethoven influenced by 1:128, 1:129
 father's role in training 1:503
 friendship with Haydn 1:584
 imaginal overexcitability 2:205
 as prodigy 2:262
 Salieri's reputation *vs* 2:263
 Mozart effect 2:171
 MPAA ratings 1:107, 1:512
 definition 1:107, 1:509
 Mullis, Kary 1:559, 1:653
 multicomponent model of working memory 2:296
 multidimensional views (art and science) 1:e21–e22
 multidisciplinary, definition 2:446
 multidisciplinary programs/courses 2:266, 2:269
 multidisciplinary teams 2:448
 multifaceted, definition 2:266
 multifaceted nature of creativity 1:86–87, 1:234
 multifaceted people 2:50
 multilevel theory of creativity 1:292
 multi-pass processes 2:75
 scientific discoveries 2:80–81
 Multiple Creative Talent Teaching model 2:427
 multiple discovery 1:393–394, 2:153–160, 2:537
 amorphous nature 2:154
 contextual incongruence 2:158
 cultural issues 2:159
 debate 2:159
 arguments supporting 2:153
 critics of 2:153–154, 2:157, 2:158
 definition 2:153, 2:533
 difficulties in attributing discoveries 2:153
 discoverers making 1:389, 2:153, 2:154–156
 evidence for sociocultural determinism 2:537
 historical examples 2:153, 2:154–156, 2:537
 outside sciences 1:394–395
 philosophy and logic 2:159
 science 2:153, 2:154–156, 2:159, 2:537
 dichotomy with visual arts 2:156, 2:158, 2:159
 disputes 2:154
 institutional practices/values 2:154–155
 photography discovery 2:157–158
 priority controversies 2:154–155
 unexpected discoveries 2:155–156
 visual arts *vs* 2:156–158, 2:159
 time lag before acceptance 2:158, 2:159
 unresolved questions on creativity 2:159
 visual arts 2:156–158
 critics 2:157, 2:158
 Galileo and Moon 2:156–157
 individual contributions 2:156–158
 oil painting invention 2:156
 photography 2:157–158
 multiple intelligences 2:161–165
 assessment 2:163–164
 difficulties 2:163–164
 bottlenecking 2:163
 catalysis 2:163
 compensation 2:163
 creativity and 2:164–165
 appropriateness issue 2:165
 novelty issue 2:164
 criteria for 2:162
 cultures and 2:164
 definition 1:335, 1:564, 2:162
 domains and 2:163
 equipotentiality 2:162
 Gardner's theory 2:161, 2:162, 2:233, 2:428

 Murray, Grace Brewster *see* Hopper, Grace Murray
 muse 1:303, 2:244
 creative thoughts from gods via 1:608–609
 definition 1:608
 Musée Rodin 1:204
 Muses, the 1:653
 mushin (state of 'no mind') 2:539, 2:540
 music 2:166–174
 arousal level stabilization 2:171
 benefits 2:171
 cerebral processing 2:170–171, 2:171f
 language overlap 2:170–171
 Chinese 2:168
 classical, problem-solving with 2:171
 complexity, for creative people 2:172
 composer–score–performer division 1:650
 composition 2:166
 flow in 1:523
 creativity *see* musical creativity
 definition 2:166
 education for women 2:331
 emotional experiences and 2:166, 2:169–170, 2:171, 2:172–173
 expression and induction 2:170
 peak experience 2:169, 2:170
 technique for building 2:169–170
 evolution and reasons for 2:172–173
 expressive arts therapy 1:500
 flow in 1:523–524
 friendships in 1:539–540
 genres 1:651
 group flow 1:526
 harmonic series 2:167–168
 historical development 2:168, 2:173
 homospatial process 2:4
 improvisation *see* improvisation
 Indian 2:168
 Janusian process in 2:3, 2:7
 language relationship 2:170–171, 2:172
 learning, flow state 1:523–524
 listening, teaching of 2:218

- major vs minor modes 2:169, 2:171
 mathematics and, cross-disciplinary approach 1:290, 2:172
 notation 2:168
 history 2:167, 2:168f
 origins 2:167–168
 prehistory 2:167
 perception, echoic memory and 2:88
 performance
 flow in 1:523
 group flow and 1:526
 primitive, Gestalt analysis 2:516
 rehearsals vs concert, flow in 1:526
 scored, improvisation unusual 1:647–648
 scores, early historical 2:167, 2:168f
 septic articulation process 2:6–7
 simple ratios 2:167–168
 sound of *see* musical sound
 sounds of nature and 2:166
 spatial-temporal problem-solving 2:171
 stylistic content, war impact on 2:511
 as suicide protective mechanism 2:397
 synesthesia (colored hearing) 2:407
 training, creativity enhancement 2:172
 types, suicide relationship 2:401
 uses 2:171–172
 health benefits 2:171–172
 Mozart effect and verbal task performance 2:171
 music therapy 2:166, 2:171
 of Vedda, Wertheimer's study 2:516
 war impact on creativity 2:511, 2:536–537
 whole determining nature of parts 2:516
- musical ability
 discoverers 1:388–389
 echoic memory parameters and 2:88–89
 genetic association studies 1:561–562
 nature vs nurture influencing 2:168–169
- musical creativity 1:539, 2:172
 definition 2:166
- musical grammar 2:170–171, 2:172
- musical instruments, early (historical) 2:167, 2:167f
- musical intelligence 1:132, 1:404, 2:162, 2:163
- musical skills 2:172
- musical sound 2:166
 definition 2:166
- Musical Theatre 2:470
- music awards cluster 1:110
 definition 1:509
- music-hall traditions, influence on Chaplin (Charlie) 1:192, 1:194
- musicians
 brain lateralization 2:170
 church, historical 2:168
 cognitive mechanisms for expert performance 1:493, 1:494–495
 decreased creativity with competition 2:151
 deliberate practice time 1:492–493, 1:493f
 discoveries by 1:394
 drug abuse 2:393, 2:394
