1.1 Introduction

Visual Basic .NET is a radically new version of Microsoft Visual Basic, the world's most widely used rapid application development (RAD) package. Visual Basic .NET is designed to work directly with Microsoft's .NET platform, which includes a Framework Class Library to facilitate application development, a Common Language Runtime to provide a managed execution environment, and a Common Type System to insure interoperability among all languages that support the .NET platform.

The *Visual Basic .NET Language Pocket Reference* is a quick reference guide to Visual Basic 7.0, the first version of Visual Basic .NET. It contains a concise description of all language elements by category. These include language elements implemented by the Visual Basic compiler, as well as all procedures and functions implemented in the `Microsoft.VisualBasic` namespace. It does not attempt to document the core classes of the .NET Framework Class Library.

The purpose of this quick reference is to aid readers who need to look up some basic detail of Visual Basic syntax or usage. It is not intended to be a tutorial or user guide; at least a basic familiarity with Visual Basic is assumed.

1.2 Font Conventions

Constant Width

Used to indicate code examples, types and type members, statements, constants, and keywords.

Constant Width Italic

Used to indicate replaceable parameters.

Italic

Used to indicate new terms, filenames, URLs, and email addresses.

1.3 Visual Basic Conventions

The "rules" for Visual Basic (VB) code are very simple:

- VB is a case-insensitive programming language; that is, the compiler ignores case when reading VB code. So *myVar*, *MyVar*, *MYvar*, and *MYVAR* all refer to the same variable. Note that Visual Studio imposes a uniform casing on all language elements, although this is not a requirement of the compiler.
- White space (except for line breaks) is ignored when reading VB code.
- Line breaks mark the end of a complete statement; complete VB statements must occupy a single line.
- If you want to break a single statement over several lines, you can use the line continuation character, an underscore (`_`), which must be preceded by a space and must be the last character on the line that is to be continued.
- If you want to combine multiple statements on a single line, you can use the colon (`:`). Among other uses, it is commonly used to imitate C++ and C# syntax for inheritance. For example, the code fragment:
 - ```
Public Class MainForm
 Inherits Form
```

can be shortened as follows:

```
Public Class MainForm : Inherits Form
```

- Two comment symbols are used: the apostrophe (`'`) and the `Rem` keyword. They may appear at any place within a line.

## 1.4 Data Types

Whether VB is a weakly or a semi-strongly typed language depends on the `Option Explicit` setting. (The statement must appear at the top of a code module.) If `Off`, VB is a weakly typed language; variables need not be declared in advance, and all undeclared variables will be cast as type `Object` until they are initialized. If `On` (its default setting), each variable must be declared in advance, but its data type need not be specified. If no type is explicitly declared, variables are cast as type `Object` until their first use.

Although VB recognizes a number of "intrinsic" data types, each is really a wrapper around a data type found in the .NET Common Type System (CTS). VB recognizes the following intrinsic types:

### *Boolean*

A logical (`True` or `False`) value. Corresponds to `System.Boolean`.

### *Byte*

A signed 8-bit numeric data type. Corresponds to `System.Byte`.

### *Char*

A 16-bit character data type (character code). Corresponds to `System.Char`.

### *Date*

A date or time value. Corresponds to `System.DateTime`.

### *Decimal*

A decimal or currency value. Corresponds to `System.Decimal`.

### *Double*

A double-precision floating point value. Corresponds to `System.Double`.

### *Integer*

A signed 32-bit integral data type. Corresponds to `System.Int32`.

### *Long*

A signed 64-bit integral data type. Corresponds to `System.Int64`.

### *Object*

A reference to an object. `Object` is VB's "universal" data type and corresponds to `System.Object`.

### *Short*

A signed 16-bit integral data type. Corresponds to `System.Int16`.

### *Single*

A single-precision floating point value. Corresponds to `System.Single`.

### *String*

A reference type pointing to a fixed-length character string. Corresponds to `System.String`.

A number of other data types are available from the .NET CTS but are not wrapped by a corresponding VB intrinsic data type. These include:

`System.SByte`

A signed 8-bit integral data type.

`System.UInt16`

An unsigned 16-bit integral data type.

`System.UInt32`

An unsigned 32-bit integral data type.

`System.UInt64`

An unsigned 64-bit integral data type.

VB also allows you to create user-defined reference types by using the `Class...End Class` construct and user-defined value types by using the `Structure...End Structure` construct.

Any of these data types can be used as a member of an array. Arrays can have a single dimension, or they can be multidimensional (up to 60 dimensions). The first element in an array is always at position 0.

## 1.5 Variables

VB does not require that variables be declared before they are used unless `Option Explicit` is `On` (its default value). In that case, you can declare variables using the `Dim`, `Public`, `Private`, `Protected`, `Friend`, or `Protected Friend` statements.

A variable name in VB must satisfy the following requirements:

- It must be 16,383 or fewer characters in length.
- It must begin with an alphabetic character or an underscore.
- It cannot include embedded spaces.
- It cannot contain any special (i.e., non-alphabetic, non-numeric) character other than an underscore.
- It must be unique within its scope.

## 1.6 Operators and Precedence

VB supports the following operators:

| Operator | Description                               |
|----------|-------------------------------------------|
| +        | Addition, string concatenation            |
| +=       | Increment and assign                      |
| -        | Subtraction, unary operator               |
| -=       | Subtract and assign                       |
| /        | Division                                  |
| /=       | Divide and assign                         |
| \        | Integer division (no remainder)           |
| \=       | Integer division and assignment           |
| Mod      | Modulo arithmetic                         |
| *        | Multiplication                            |
| *=       | Multiply and assign                       |
| ^        | Exponentiation                            |
| ^=       | Exponentiation and assignment             |
| &        | String concatenation                      |
| &=       | String concatenation and assignment       |
| =        | Equality, assignment                      |
| Is       | Equality (for object references)          |
| <        | Less than                                 |
| <=, =<   | Less than or equal to                     |
| >        | Greater than                              |
| >=, =>   | Greater than or equal to                  |
| <>, ><   | Not equal to                              |
| And      | Logical or bitwise conjunction            |
| AndAlso  | Logical conjunction with short-circuiting |
| Or       | Logical or bitwise disjunction            |
| OrElse   | Logical disjunction with short-circuiting |
| Not      | Logical or bitwise negation               |
| Xor      | Logical or bitwise exclusion              |

Expressions are evaluated in the following order:

1. Arithmetic operators
  - a. Exponentiation

- b. Division and multiplication
  - c. Integer division
  - d. Modulo arithmetic
  - e. Addition and subtraction
- 2. Concatenation operators
  - 3. Logical operators
    - a. Not
    - b. And, AndAlso
    - c. Or, OrElse
    - d. X

If two or more operators in an expression have the same order of precedence, they are evaluated from left to right.

## 1.7 Constants

VB recognizes the following intrinsic constants:

### 1.7.1 Call Type Constants

|       |          |
|-------|----------|
| vbGet | vbMethod |
| vbLet | vbSet    |

### 1.7.2 Comparison Constants

|                 |               |
|-----------------|---------------|
| vbBinaryCompare | vbTextCompare |
|-----------------|---------------|

### 1.7.3 Date and Time Constants

|             |                      |
|-------------|----------------------|
| vbSunday    | vbSaturday           |
| vbMonday    | vbUseSystem          |
| vbTuesday   | vbUseSystemDayOfWeek |
| vbWednesday | vbFirstJan1          |
| vbThursday  | vbFirstFourDays      |
| vbFriday    | vbFirstFullWeek      |

### 1.7.4 Date Format Constants

|               |             |
|---------------|-------------|
| vbGeneralDate | vbShortDate |
| vbLongDate    | vbShortTime |
| vbLongTime    |             |

### 1.7.5 Error Constant

|               |
|---------------|
| vbObjectError |
|---------------|

### 1.7.6 File Attributes

|             |          |
|-------------|----------|
| vbArchive   | vbNormal |
| vbDirectory | vbSystem |
| vbHidden    | vbVolume |
| vbReadOnly  |          |

## 1.7.7 Logical and Tristate Constants

|         |              |
|---------|--------------|
| False   | vbTrue       |
| True    | vbUseDefault |
| vbFalse |              |

## 1.7.8 Message Box Constants

### 1.7.8.1 Buttons constants

|                    |               |
|--------------------|---------------|
| vbAbortRetryIgnore | vbRetryCancel |
| vbMsgBoxHelp       | vbYesNo       |
| vbOKCancel         | vbYesNoCancel |
| vbOKOnly           |               |

### 1.7.8.2 Default button constants

|                  |                  |
|------------------|------------------|
| vbDefaultButton1 | vbDefaultButton3 |
| vbDefaultButton2 |                  |

### 1.7.8.3 Icon constants

|               |               |
|---------------|---------------|
| vbCritical    | vbInformation |
| vbExclamation | vbQuestion    |

### 1.7.8.4 Modality constants

|                    |               |
|--------------------|---------------|
| vbApplicationModal | vbSystemModal |
|--------------------|---------------|

### 1.7.8.5 Return value constants

|          |         |
|----------|---------|
| vbAbort  | vbOK    |
| vbCancel | vbRetry |
| vbIgnore | vbYes   |
| vbNo     |         |

### 1.7.8.6 Miscellaneous constants

|                    |                       |
|--------------------|-----------------------|
| vbMsgBoxRight      | vbMsgBoxSetForeground |
| vbMsgBoxRtlReading |                       |

## 1.7.9 Special Character Constants

|            |               |
|------------|---------------|
| vbBack     | vbNewLine     |
| vbCr       | vbNullChar    |
| vbCrLf     | vbNullString  |
| vbFormFeed | vbTab         |
| vbLf       | vbVerticalTab |

### 1.7.10 Variable Subtype Constants

|            |                   |
|------------|-------------------|
| vbArray    | vbInteger         |
| vbBoolean  | vbLong            |
| vbByte     | vbNull            |
| vbCurrency | vbObject          |
| vbDate     | vbSingle          |
| vbDecimal  | vbString          |
| vbDouble   | vbUserDefinedType |
| vbEmpty    | vbVariant         |

### 1.7.11 Window Style Constants

|                    |                      |
|--------------------|----------------------|
| vbHide             | vbNarrow             |
| vbHiragana         | vbNormalFocus        |
| vbKatakana         | vbNormalNoFocus      |
| vbLinguisticCasing | vbProperCase         |
| vbLowerCase        | vbSimplifiedChinese  |
| vbMaximizedFocus   | vbTraditionalChinese |
| vbMinimizedFocus   | vbUpperCase          |
| vbMinimizedNoFocus | vbWide               |

User-defined constants can be declared using the `Const` statement.

## 1.8 Enumerations

The `Microsoft.VisualBasic` namespace also defines a number of enumerations. Many of their members are functionally identical to almost identically named constants listed in the aforementioned [Section 1.7](#).

### 1.8.1 AppVisualStyle Enumeration

Determines the appearance and behavior of the window opened by the *Shell* function.

|                |                  |
|----------------|------------------|
| Hide           | MinimizedNoFocus |
| MaximizedFocus | NormalFocus      |
| MinimizedFocus | NormalNoFocus    |

### 1.8.2 CallType Enumeration

Defines the type of procedure invoked by the *CallByName* function.

|        |     |
|--------|-----|
| Get    | Set |
| Method |     |

### 1.8.3 CompareMethod Enumeration

Used with a variety of string comparison methods (such as *InStr*, *StrComp*, and *Replace*) to determine whether the comparison is case sensitive or insensitive.

|        |      |
|--------|------|
| Binary | Text |
|--------|------|

### 1.8.4 ControlChars Class

Values representing a number of control characters are available as static read-only fields of the `ControlChars` class. They can be referenced just as enumerated members; for example:

```
Addr = "123 West St. & ControlChars.CrLf & _
 "Apt. 12C"
```

|          |             |
|----------|-------------|
| Back     | NewLine     |
| Cr       | NullChar    |
| CrLf     | Quote       |
| FormFeed | Tab         |
| Lf       | VerticalTab |

### 1.8.5 DateFormat Enumeration

Defines the format of the date returned by the *FormatDateTime* function.

|             |           |
|-------------|-----------|
| GeneralDate | ShortDate |
| LongDate    | ShortTime |
| LongTime    |           |

### 1.8.6 DateInterval Enumeration

Defines the date interval for date/time functions, such as *DateDiff*, *DatePart*, and *DateAdd*.

|           |            |
|-----------|------------|
| Day       | Quarter    |
| DayOfYear | Second     |
| Hour      | Weekday    |
| Minute    | WeekOfYear |
| Month     | Year       |

### 1.8.7 DueDate Enumeration

Used with the *FV*, *IPmt*, *NPer*, *Pmt*, *PPmt*, *PV*, and *Rate* functions to define whether a payment is due at the beginning or end of a period.

|             |             |
|-------------|-------------|
| BegOfPeriod | EndOfPeriod |
|-------------|-------------|

### 1.8.8 FileAttribute Enumeration

Used with the *Dir*, *GetAttr*, and *SetAttr* functions to set a file's attributes or to retrieve files with particular attributes set.

|           |          |
|-----------|----------|
| Archive   | ReadOnly |
| Directory | System   |
| Hidden    | Volume   |
| Normal    |          |

### 1.8.9 FirstDayOfWeek Enumeration

Used with the *DatePart*, *DateDiff*, *Weekday*, and *WeekdayName* functions to define the first day of the week and to interpret the function's return value.

|          |           |
|----------|-----------|
| Friday   | System    |
| Monday   | Tuesday   |
| Saturday | Thursday  |
| Sunday   | Wednesday |

### 1.8.10 FirstWeekOfYear Enumeration

Used with the *DatePart* and *DateDiff* functions to define the first week of the year and to interpret the function's return value.

|               |        |
|---------------|--------|
| FirstFourDays | Jan1   |
| FirstFullWeek | System |

### 1.8.11 MsgBoxResult Enumeration

Represents the return value of the *MsgBox* function.

|        |       |
|--------|-------|
| Abort  | OK    |
| Cancel | Retry |
| Ignore | Yes   |
| No     |       |

### 1.8.12 MsgBoxStyle Enumeration

Defines the appearance and behavior of a message box.

|                  |                     |
|------------------|---------------------|
| AbortRetryIgnore | MsgBoxRtlReading    |
| ApplicationModal | MsgBoxSetForeground |
| Critical         | OKCancel            |
| DefaultButton1   | OKOnly              |
| DefaultButton2   | Question            |
| DefaultButton3   | RetryCancel         |
| Exclamation      | SystemModal         |
| Information      | YesNo               |
| MsgBoxHelp       | YesNoCancel         |
| MsgBoxRight      |                     |

### 1.8.13 OpenAccess Enumeration

Used with the *FileOpen* function to determine how the file can be accessed.

|         |           |
|---------|-----------|
| Default | ReadWrite |
| Read    | Write     |

### 1.8.14 OpenMode Enumeration

Used with the *FileOpen* function and returned by the *FileAttr* function and indicates the file access mode. The `Microsoft.VisualBasic` namespace also defines an `OpenModeTypes` enumeration that is identical to

OpenMode except for adding an Any member.

|        |        |
|--------|--------|
| Append | Output |
| Binary | Random |
| Input  |        |

### 1.8.15 OpenShare Enumeration

Used with the *FileOpen* function to determine the file's share level.

|               |           |
|---------------|-----------|
| Default       | LockWrite |
| LockRead      | Shared    |
| LockReadWrite |           |

### 1.8.16 TriState Enumeration

Used with the *FormatCurrency*, *FormatNumber*, and *FormatPercent* functions to control the format of a number.

|       |            |
|-------|------------|
| False | UseDefault |
| True  |            |

### 1.8.17 VariantType Enumeration

Returned by the *VarType* function to indicate the data type of a variable.

|            |                 |
|------------|-----------------|
| Array      | Error           |
| Boolean    | Integer         |
| Byte       | Long            |
| Char       | Null            |
| Currency   | Object          |
| DataObject | Short           |
| Date       | Single          |
| Decimal    | String          |
| Double     | UserDefinedType |
| Empty      | Variant         |

### 1.8.18 VbStrConv Enumeration

Supplied as a parameter to the *StrConv* function to indicate how a string is to be converted.

|                  |                    |
|------------------|--------------------|
| Hiragana         | ProperCase         |
| Katakana         | SimplifiedChinese  |
| LinguisticCasing | TraditionalChinese |
| LowerCase        | UpperCase          |
| Narrow           | Wide               |
| None             |                    |

## 1.9 Object Programming

Unlike previous versions of VB, VB.NET is a fully object-oriented programming language. This object orientation has two aspects: access to the .NET Framework Class Library (FCL), and the ability to define and instantiate custom classes using inheritance.

### 1.9.1 .NET Framework Class Library

The .NET Framework Class Library is an object-oriented library consisting of thousands of system and application types (classes, structures, interfaces, delegates, and enumerations) organized in namespaces. The namespaces and types of the .NET FCL offer a wide range of functionality, from wrappers to classic Win32 API functions to diagnostics and debugging to input/output to data access, Windows forms programming, and web application and web service development. In fact, most of the "intrinsic" functions and procedures that are part of the VB.NET language are implemented as members of classes in the `Microsoft.VisualBasic` namespace.

In order to access the types in a namespace, the compiler must be provided with a reference to its assembly. This is done with the `/r` switch using the VB command line compiler. When a type is instantiated or a type member is invoked, ordinarily the type's fully qualified namespace must be included. For example, a new instance of an `ApplicationException` class is generated by the following code fragment:

```
Dim e As New System.ApplicationException()
```

As an alternative, you can have the compiler or the Visual Studio design-time resolve an unqualified object reference by using the `Imports` directive to import a type's namespace. The `Imports` directive appears at the top of a file, after any `Option` statements and before any type or module definitions. Using `Imports`, we can instantiate an `ApplicationException` object as follows:

```
Dim e As New ApplicationException()
```

### 1.9.2 Custom Types and Classes

In addition to accessing the functionality of the .NET FCL, you can also define your own custom types, including custom classes. In defining a class, you can take advantage of *inheritance*; that is, you can indicate that your class derives from another class, either from a class in the .NET FCL or from another custom class. In this case, your class automatically inherits the functionality of its base class. You can even take advantage of inheritance without explicitly specifying an inherited class. All classes automatically inherit from type `System.Object`, and all structures (which cannot take advantage of inheritance directly) automatically inherit from type `System.ValueType`. For instance, consider the following code:

```
Public Class AppClass
Public Shared Sub Main
 Dim obj As New AppClass
 System.Console.WriteLine(obj.ToString)
End Sub
End Class
```

When compiled, the code produces the following output:

## AppClass

The code calls the `AppClass.ToString` method. But the `ToString` method isn't explicitly defined; instead, it is inherited from the `Object` class.

Along with inherited members, you can also access any members that you defined in your class. Any particular class member can be either an *instance* member or a *shared* member. Instance members require that an object of the class be instantiated, and that the member (and its value, if there is one) belongs to that instance. Shared members do not require an object instance, and instead can be invoked using the class itself. If a shared member has a value, it is shared across all instances of a class.

VB supports three different kinds of members: fields, properties, and methods. The following section examines each of these.

### 1.9.3 Fields, Properties, and Methods

A *field* is simply a publicly accessible constant or variable. Because it is usually undesirable to give users of a class unrestricted access to its data, fields typically consist of constants or read-only variables. (Read-only variables are not completely read-only; values can be assigned to them when the variable is declared and initialized, as well as in the class constructor.) For example:

```
Public Class FieldClass
 Public ReadOnly Value As Integer = 100
 Public Const Pi = Math.Pi

 Public Sub New()
 End Sub

 Public Sub New(x As Integer)
 Value = x
 End Sub
End Class
```

A *property* provides a public interface to a class' state information. A property can consist of either a get accessor (which returns the property value), a set accessor (which sets the property value), or both. For example, the following code defines an `Age` property for the `Employee` class:

```
Public Class Employee

 Private EmployeeAge As Integer

 Public Property Age() As Integer
 Get
 Return EmployeeAge
 End Get
 Set
 EmployeeAge = Value
 End Set
 End Property
```

End Class

A *method* represents an action or operation that is performed upon the class. VB recognizes functions, which are declared with the `Function...End Function` construct, and subroutines, which are declared with the `Sub...End Sub` construct. Functions return a value to the caller; subroutines do not. Both functions and subroutines can include a list of parameters to be passed to the procedure by the caller. For example:

```
Public Class MathLib
 Public Sub SwapNumbers(ByRef Num1 As Integer, _
 ByRef Num2 As Integer)
 Dim Temp As Integer
 Temp = Num2
 Num2 = Num1
 Num1 = Temp
 End Sub

 Public Function Pi() As Double
 Return System.Math.Pi
 End Function
End Class
```

By default, arguments are passed to functions and subroutines *by value*; that is, the function or subroutine is provided with a copy of the argument, and any changes made to the argument by the function or subroutine are discarded when control returns to the caller. This behavior can be overridden, and an argument can be passed to a function or subroutine *by reference*; that is, the address of the data is provided to the function or subroutine. To pass an argument by reference, precede the parameter in the function or subroutine's parameter list with the `ByRef` keyword.

You can call a subroutine in either of the following ways:

```
oMath.SwapNumbers(x, y)
Call oMath.SwapNumbers(x, y)
```

You call a function as follows:

```
Result = oMath.Pi()
```

However, if you're not interested in the function's return value, you can also call the function as if it were a subroutine.

## 1.10 Program Structure

When a class or structure is instantiated, its class constructor (which in VB is a subroutine named `New`) is automatically invoked. In addition, each executable requires an entry point in the form of a function or subroutine named `Main`. For example:

```
Public Class PgmStruct

 Private Value As Integer

 Public Sub New(x As Integer)
 Value = x
 End Sub

 Public Shared Sub Main()
 Dim obj As New PgmStruct(100)
 Console.WriteLine(obj.Value)
 End Sub
End Class
```

## 1.11 Array Handling

### Erase Statement

---

`Erase arraylist`

*arraylist* required; String literal

A list of array variables to clear

### Description

Releases an array object. This is equivalent to setting the array variable to `Nothing`. More than one array can be specified by using commas to delimit *arraylist*.

### IsArray Function

**Microsoft.VisualBasic.Information**

`IsArray(varname)`

*varname* required; any variable

A variable that may be an array

### Return Value

Boolean (True or False)

### Description

Tests whether an object variable points to an array. Note that an uninitialized array returns `False`.

### Join Function

**Microsoft.VisualBasic.Strings**

`result = Join(sourcearray, [delimiter])`

*sourcearray* required; String or Object array

Array whose elements are to be concatenated

*delimiter* optional; String

Character used to delimit the individual values in the string

## Return Value

String

## Description

Concatenates an array of values into a delimited string using a specified *delimiter*, or, if no *delimiter* is specified, a space.

## LBound Function

## Microsoft.VisualBasic.Information

```
LBound(array[, rank])
```

*array* required; any array

An array whose lower bound is to be determined

*rank* optional; Integer

The dimension whose lower bound is desired

## Return Value

An Integer whose value is 0

## Description

Determines the lower boundary of a specified dimension of an array. The lower boundary is the smallest subscript you can access within the specified array.

## ReDim Statement

```
ReDim [Preserve] varname(subscripts) _
 [, varname(subscripts) ...]
```

Preserve optional; Keyword

Preserves the data within an array when changing the only or last dimension

*varname* required; String literal

Name of the variable

*subscripts* required; Numeric

Number of elements and dimensions of the array, using the syntax:

*upper* [, *upper*] ...

The number of upper bounds specified is the number of dimensions. Each upper bound specifies the size of the corresponding coordinate.

## Description

Used within a procedure to resize and reallocate storage space for an array

### UBound Function

### Microsoft.VisualBasic.Information

UBound(*array*[, *rank*])

*array* required; Any

The name of the array

*rank* optional; Integer

A number specifying the dimension of the array; if omitted, its value defaults to 1

### Return Value

Integer; returns -1 if the array is uninitialized

## Description

Indicates the upper limit of a specified coordinate of an array. The upper boundary is the largest subscript you can use with that coordinate.

### VBFixedArray Attribute

### Microsoft.VisualBasic.VBFixedArrayAttribute

New(*size1*[, *size2*])

*size1* required; Integer

The upper limit of the array's first dimension

*size2* optional; Integer

The upper limit of the array's second dimension

## Description

Defines a fixed array. It can be used in defining fixed arrays within structures, particularly structures that are to be passed to Win32 API functions.

## 1.12 Collection Objects

### Collection.Add Method

Microsoft.VisualBasic.Collection

---

*objectvariable*.Add *item* [, *key*, *before*, *after*]

*objectvariable* required; Collection Object

The Collection object to which an item is to be added

*item* required; Object

An object of any type that specifies the member to add to the collection

*key* optional; String

A unique string expression that specifies a key string that can be used, instead of a positional index, to access a member of the collection

*before* optional; Object

Index or key of the item after which the new item is to be added

*after* optional; Object

Index or key of the item before which the new item is to be added

### Description

Adds an item to a particular position in a collection, or to the end of the collection if no position is specified.

### Collection.Count Property

Microsoft.VisualBasic.Collection

*objectvariable*.Count

*objectvariable* required; Collection Object

An object variable of type `Collection`

### Description

Returns an Integer containing the number of members in the collection.

### Collection.Item Method

Microsoft.VisualBasic.Collection

---

*objectvariable*.Item(*index*)

*objectvariable* required; Collection Object

An object variable of type Collection

*index* required; Integer or String

The index (the ordinal position) or the unique key name of the object in the collection

## Description

Returns the member of the collection for the specified key or ordinal position.

### Collection.Remove Method

### Microsoft.VisualBasic.Collection

---

*objectvariable*.Remove(*index*)

*objectvariable* required; Collection Object

An object variable of the Collection type

*index* required; Integer or String

The ordinal position or the unique key name of the item to remove

## Description

Removes a member from a collection.

## 1.13 Conditional Compilation

### #Const Directive

---

```
#Const constantname = expression
```

*constantname* required; String literal

Name of the constant

*expression* required; literal

Any combination of literal values, other conditional compilation constants defined with the #Const directive, and arithmetic or logical operators except `Is`

### Description

Defines a conditional compiler constant.

### #If ... Then ... #Else Directive

```
#If expression Then
 statements
[#ElseIf furtherexpression Then
 [elseifstatements]]
[#Else
 [elsestatements]]
#End If
```

*expression* required

An expression made up of literals, operators, and conditional compiler constants that will evaluate to `True` or `False`

*statements* required

One or more lines of code or compiler directives, which is executed if *expression* evaluates to `True`

*furtherexpression* optional

An expression made up of literals, operators, and conditional compiler constants that will evaluate to `True` or `False`. *furtherexpression* is only evaluated if the preceding expression evaluates to `False`

*elseifstatements* optional

One or more lines of code or compiler directives, which is executed if *furtherexpression* evaluates to `True`

*elstatements* optional

One or more lines of code or compiler directives, which are executed if *expression* or *furtherexpression* evaluates to `False`

## Description

Defines a block or blocks of code that are only included in the compiled application when a particular condition is met, allowing you to create more than one version of the application using the same source code.

Conditionally including a block of code is a two-step process:

- Use the `#Const` directive to assign a value to a conditional compiler constant.
- Evaluate the conditional compiler constant using the `#If...Then...#End If` statement block.

Only code blocks whose expressions evaluate to `True` are included in the executable. You can use the `#Else` statement to execute code when the `#If...Then` expression evaluates to `False`. You can also use an `#ElseIf` statement to evaluate more expressions if previous expressions in the same block have evaluated to `False`.

## CBool Function

`CBool(expression)`

*expression* required; String or Numeric

Any numeric expression or a string representation of a numeric value

## Named Arguments

No

## Return Value

*expression* converted to Boolean data type (`True` or `False`)

## Description

Casts *expression* as a Boolean data type. When a numeric value is converted to Boolean, any nonzero value is converted to `True`, and zero is converted to `False`.

If the expression to be converted is a string, the string must be capable of being evaluated as a number, or it must be "True" or "False". Any other string generates an exception. For example, `CBool("one")` results in a type mismatch error, whereas `CBool("1")` is converted to `True`, and `CBool("True")` is converted to `True`.

## CByte Function

---

`CByte(expression)`

*expression* required; String or Numeric

A string or numeric expression that evaluates to a number between 0 and 255

### Named Arguments

No

### Return Value

*expression* converted to Byte data type

### Description

Converts *expression* to a Byte data type. If the expression to be converted is a string, the string must be capable of conversion to a numeric expression; this can be checked using the *IsNumeric* function. If *expression* evaluates to less than 0 or more than 255, an exception is generated. If the value of *expression* is not a whole number, *CByte* rounds the number prior to conversion.

## CChar Function

`CChar(expression)`

*expression* required; String

Any string expression

### Named Arguments

No

### Return Value

A value of type Char

### Description

Converts the first character in a string *expression* to a Char data type.

## CDate Function

---

*CDate(expression)*

*expression* required; String or Numeric

Any valid representation of a date and time

### Named Arguments

No

### Return Value

*expression* converted into a Date data type

### Description

Converts *expression* to a Date data type. The format of *expression*-the order of day, month, and year-is determined by the locale setting of the local computer. To be certain a date is recognized correctly by *CDate*, the month, day, and year elements of *expression* must be in the same sequence as the local computer's regional settings; otherwise, the *CDate* function has no idea, for example, that 4 was supposed to be the fourth day of the month, not the month of April. The earliest date that can be handled by the Date data type is 01/01/100. The latest date that can be handled by the Date data type is 12/31/9999.

## Cdbl Function

*Cdbl(expression)*

*expression* required; Numeric or String

A number or a string representation of a number

### Named Arguments

No

### Return Value

*expression* cast as a Double data type

## Description

Converts *expression* to a Double data type. If *expression* is not numeric, or if its value is outside the range of the Double data type, an exception is generated.

### CDec Function

---

`CDec(expression)`

*expression* required; Numeric or String

A numeric value or a string representation of a number

### Named Arguments

No

### Return Value

*expression* cast as a Decimal type

## Description

Converts *expression* to a Decimal data type. If *expression* is not numeric or is outside the range of the Decimal data type, an exception is generated. Use the *IsNumeric* function to test whether *expression* evaluates to a number.

### CInt Function

`CInt(expression)`

*expression* required; Numeric or String

A numeric value or a string representation of a number

### Named Arguments

No

### Return Value

*expression* cast as an Integer

## Description

Converts *expression* to an Integer data type. If *expression* has a fractional value, it is rounded. When the fractional part of *expression* is exactly .5, *CInt* always rounds it to the nearest even number. If *expression* is not numeric or is outside the range of the Integer data type, an exception is generated. Use *IsNumeric* to test whether *expression* evaluates to a number.

## CLng Function

---

*CLng(expression)*

*expression* required; Numeric or String

A number or a string representation of a number

## Named Arguments

No

## Return Value

*expression* cast as a Long data type

## Description

Converts *expression* to a long integer; any fractional element of *expression* is rounded. When the fractional part is exactly .5, *CLng* always rounds it to the nearest even number. If *expression* is not numeric or is outside the range of the Long data type, an exception is generated. Use *IsNumeric* to test whether *expression* evaluates to a number.

## CObj Function

*CObj(expression)*

*expression* required; any

Expression to be converted to type Object

## Named Arguments

No

## Return Value

*expression* cast as an Object data type

## Description

Converts any expression that can be interpreted as an object to Object. *expression* can be any data type, including a strongly typed object, as the following code fragment illustrates:

```
Dim oSomeClass As New CSomeClass
Dim oObj As Object
oObj = CObj(oSomeClass)
```

## CSng Function

---

*CSng(expression)*

*expression* required; Numeric or String

The range of *expression* is -3.402823E38 to -1.401298E-45 for negative values, and 1.401298E-45 to 3.402823E38 for positive values.

## Named Arguments

No

## Return Value

*expression* cast as a Single data type

## Description

Returns a single-precision number.

## CStr Function

*CStr(expression)*

*expression* required; any

Any numeric, date, string, or Boolean expression

## Named Arguments

No

## Return Value

*expression* converted to a string

## Description

Returns a string representation of *expression*.

## CType Function

---

`CType(expression, typename)`

*expression* required; any

The data item to be converted

*typename* required; Keyword

The data type, object type, structure, or interface to which *expression* is to be converted

## Named Arguments

No

## Return Value

*expression* cast as a *typename* interface, object, structure, or data type

## Description

Converts an expression to the specified data type if possible; *expression* can be any data, object, structure, or interface type. *typename* can be any data type (such as `Boolean`, `Byte`, `Decimal`, `Long`, `Short`, `String`, etc.), structure type, object type, or interface that can be used with the `As` clause in a `Dim` statement. If the function fails, or if the converted value of *expression* is outside the range allowed by *typename*, an `InvalidCastException` exception occurs.

## DateValue Function

**Microsoft.VisualBasic.DateAndTime**

`DateValue(stringdate)`

*stringdate* required; String

A string containing any of the date formats recognized by `IsDate`

## Return Value

A Date that represents the date specified by the *stringdate* argument

## Description

Converts the string representation of a date to a Date data type while dropping any time component. The date value is formatted according to the short date setting defined by the Regional Settings applet in the Control Panel. *DateValue* can successfully recognize *stringdate* in any of the date formats recognized by *IsDate*, but the order of the day, month, and year within *stringdate* must be the same as that defined by the computer's regional settings. If you don't specify a year in your date expression, *DateValue* uses the current year from the computer's system date. *DateValue* does not return time values in a date/time string: they simply dropped. However, if *stringdate* includes an invalid time value, an exception results.

## DirectCast Function

---

```
DirectCast(expression, typename)
```

*expression* required; any

The data item to be converted

*typename* required; Keyword

The data type, object type, structure, or interface to which expression is to be converted

## Named Arguments

No

## Return Value

*expression* cast as a *typename* interface or object

## Description

Converts an expression to its runtime data type, if possible; otherwise, returns an error. *expression* must be a reference type, typically a variable of type Object. *typename* can be any data type (such as Boolean, Byte, Decimal, Long, Short, String, etc.), structure type, object type, or interface. If the function fails, an *InvalidCastException* exception occurs.

## Option Strict Statement

```
Option Strict [On | Off]
```

## Description

`Option Strict` prevents VB from making any *implicit* narrowing data type conversions, since they may involve data loss. It also causes errors to be generated for late binding, as well as for any undeclared variables. `Option Strict On` implies `Option Explicit On`. For example:

```
Dim lNum As Long = 2455622
Dim iNum As Integer = lNum
```

converts a Long (whose value can range from 9,223,372,036,854,775,808 to 9,223,372,036,854,775,807) to an Integer (whose value can range from 2,147,483,648 to 2,147,483,647). In this case, even though no data loss would result from the narrowing, `Option Strict On` would still not allow the conversion and would instead generate a compiler error.

If the `Option Strict` statement is not present in a module, `Option Strict` is `Off`. The default is `Option Strict On`. In other words, the statement:

```
Option Strict On
```

is equivalent to the statement:

```
Option Strict
```

The `Option Strict` statement must appear in the declarations section of a module before any code.

The VB compiler considers the following to be narrowing conversions:

- Short, Integer, Long, Decimal, Single, Double    Byte
- Integer, Long, Decimal, Single, Double    Short
- Long, Decimal, Single, Double    Integer
- Decimal, Single, Double    Long
- Single, Double    Decimal
- Double    Single
- Integer type or wider    Any enumerated type
- String    Char
- Object    Any type
- Any base type    Any derived type
- An interface    Any type implementing the interface
- Any type    Nothing
- Conversions between Boolean and any numeric type

- Any numeric type → any enumerated type
- Conversions between a Char array and a String
- Conversions between String and any numeric, Boolean, or Date type

## Str Function

Microsoft.VisualBasic.Conversion

---

*Str(number)*

*number* required; Numeric

Any valid numeric expression or expression capable of conversion to a number

### Return Value

A String representation of *number*

### Description

Converts *number* from a numeric to a string. If the return value is positive, the *Str* function always includes a leading space in the returned string for the sign of *number*.

## TimeValue Function

Microsoft.VisualBasic.DateAndTime

*TimeValue(stringtime)*

*stringtime* required; String

Any valid string representation of a time

### Return Value

A Date containing the time specified by the *string time* argument, with the date set to January 1 of the year 1 CE.

### Description

Converts the string representation of a time to a Date type containing the time. *stringtime* can be in any time format recognized by the *IsDate* function. Both 12- and 24-hour clock formats are valid. The Date value returned by time is formatted based on the system's regional settings. If *stringtime* is invalid or is *Nothing*, an exception is raised.

## Val Function

Microsoft.VisualBasic.Conversion

---

`Val(expression)`

*expression* required; String or Char

Any string representation of a number

## Return Value

A Double able to hold the number contained in *expression*

## Description

Converts a string representation of a number into a Double. The *Val* function starts reading the string with the leftmost character and stops at the first character that it does not recognize as being part of a valid number. For example, the statement:

```
iNumber = Val("1A1")
```

returns 1.

&O and &H (the octal and hexadecimal prefixes) are recognized by the *Val* function and the period (.) is recognized as a decimal delimiter. Currency symbols, such as \$ and £, and delimiters, such as commas, are not recognized. Prior to processing *expression*, *Val* removes spaces, tabs, and line-feed characters.

## ValDec Function

## Microsoft.VisualBasic.Conversion

`ValDec(expression)`

*expression* required; String or Char

Any string representation of a number

## Return Value

A Decimal able to hold the number contained in *expression*

## Description

Converts a string representation of a number into a Decimal. The *ValDec* function starts reading the string with the leftmost character and stops at the first character that it does not recognize as being part of a valid number. For example, the statement:

```
iNumber = ValDec("1A1")
```

returns 1.

&O and &H (the octal and hexadecimal prefixes) are recognized by the *ValDec* function. Currency symbols, such as \$ and £, and delimiters, such as commas, are not recognized as numbers by the *ValDec* function. The *ValDec* function only recognizes the period (.) as a decimal delimiter. Prior to processing *expression*, *ValDec* removes spaces, tabs, and line-feed characters.

## 1.14 Other Conversion

### Fix Function

### Microsoft.VisualBasic.Conversion

---

`Fix(number)`

*number* required; Double or any numeric expression

A number whose integer portion is to be returned

### Return Value

A number of the same data type as *number* whose value is the integer portion of *number*

### Description

For nonnegative numbers, *Fix* returns the floor of the number (the largest integer less than or equal to *number*). For negative numbers, *Fix* returns the ceiling of the number (the smallest integer greater than or equal to *number*). If *number* is `Nothing`, *Fix* returns `Nothing`.

The operation of *Int* and *Fix* are identical when dealing with positive numbers: numbers are rounded down to the next lowest whole number. For example, both `Int(3.14)` and `Fix(3.14)` return 3. If *number* is negative, *Fix* removes its fractional part, thereby returning the next greater whole number. For example, `Fix(-3.667)` returns -3. This contrasts with *Int*, which returns the negative integer less than or equal to number (or -4, in the case of our example).

### Hex Function

### Microsoft.VisualBasic.Conversion

`Hex(number)`

*number* required; Numeric or String

A valid numeric or string expression

### Return Value

String representing the hexadecimal value of *number*

### Description

Converts a number to its hexadecimal (base 16) equivalent. If *number* contains a fractional part, it will be automatically rounded to the nearest whole number before the *Hex* function is evaluated. *number* must evaluate to a

numeric expression that ranges from -2,147,483,648 to 2,147,483,647. If the argument is outside of this range, an exception results. The return value of *Hex* is dependent upon the value and type of *number*:

| <b>number</b>    | <b>Return value</b>                |
|------------------|------------------------------------|
| Nothing          | Zero (0)                           |
| Any other number | Up to eight hexadecimal characters |

## **Int Function**

## **Microsoft.VisualBasic.Conversion**

*Int* (*number*)

*number* required; any valid numeric data type

The number to be processed

### **Return Value**

Returns a value of the data type passed to it

### **Description**

Returns the integer portion of a number. The fractional part of *number* is removed, and the resulting integer value is returned. *Int* does not round *number* to the nearest whole number. For example, *Int*(100.9) returns 100. If *number* is negative, *Int* returns the first negative integer less than or equal to *number*. For example, *Int*(-10.1) returns -11.

## **Oct Function**

## **Microsoft.VisualBasic.Conversion**

*Oct* (*number*)

*number* required; Numeric or String

A valid numeric or string expression

### **Return Value**

String

### **Description**

Returns the octal value of a given number. If *number* is not already a whole number, it is rounded to the nearest whole number before being evaluated. If *number* is *Nothing*, an error occurs. *Oct* returns up to 11 octal characters.

**QBColor Function****Microsoft.VisualBasic.Information**

`QBColor(color)`

*color* required; Integer

A whole number between 0-15

**Return Value**

Long

**Description**

Returns a Long integer representing the RGB system color code. *color* can have any of the following values:

|   |         |    |               |
|---|---------|----|---------------|
| 0 | Black   | 8  | Gray          |
| 1 | Blue    | 9  | Light Blue    |
| 2 | Green   | 10 | Light Green   |
| 3 | Cyan    | 11 | Light Cyan    |
| 4 | Red     | 12 | Light Red     |
| 5 | Magenta | 13 | Light Magenta |
| 6 | Yellow  | 14 | Light Yellow  |
| 7 | White   | 15 | Bright White  |

**RGB Function****Microsoft.VisualBasic.Information**

`RGB(red, green, blue)`

*red* required; Integer

A number between 0 and 255, inclusive

*green* required; Integer

A number between 0 and 255, inclusive

*blue* required; Integer

A number between 0 and 255, inclusive

**Return Value**

An Integer representing the RGB color value

## Description

Returns a system color code that can be assigned to object color properties. The RGB color value represents the relative intensity of the red, green, and blue components of a pixel that produces a specific color on the display. The *RGB* function assumes any argument greater than 255 to be 255.

The following table demonstrates how the individual color values combine to create certain colors:

| <b>Color</b> | <b>Red</b> | <b>Green</b> | <b>Blue</b> |
|--------------|------------|--------------|-------------|
| Black        | 0          | 0            | 0           |
| Blue         | 0          | 0            | 255         |
| Green        | 0          | 255          | 0           |
| Red          | 255        | 0            | 0           |
| White        | 255        | 255          | 255         |

## 1.15 Date and Time

### DateAdd Function

### Microsoft.VisualBasic.DateAndTime

`DateAdd(interval, number, datevalue)`

*interval* required; String or DateInterval enum

The interval of time to add

*number* required; Double

An expression denoting the number of time intervals you want to add (it can be positive or negative)

*datevalue* required; Date, or an expression capable of conversion to a date

The starting date to which the interval is to be added

### Return Value

A past or future Date that reflects the result of the addition

### Description

Returns a Date representing the result of adding (or subtracting, if *number* is negative) a given number of time periods to or from a given date. For instance, you can calculate the date 178 months before today's date, or the date and time 12,789 minutes from now.

*interval* can be one of the following literal strings:

|      |             |
|------|-------------|
| yyyy | Year        |
| q    | Quarter     |
| m    | Month       |
| y    | Day of year |
| d    | Day         |
| w    | Weekday     |
| ww   | Week        |
| h    | Hour        |
| n    | Minute      |
| s    | Second      |

*interval* can also be a member of the `DateInterval` enum:

```
Enum DateInterval
 Day
 DayOfYear
 Hour
 Minute
 Month
 Quarter
 Second
 Week
 Weekday
 WeekOfYear
End Enum
```

If *number* is positive, the result will be in the future; if *number* is negative, the result will be in the past. (The meaning of "future" and "past" here is relative to *datevalue*.)

The *DateAdd* function has a built-in calendar algorithm to prevent it from returning an invalid date. You can add 10 minutes to 31 December 1999 23:55, and *DateAdd* automatically recalculates all elements of the date to return a valid date, in this case 1 January 2000 00:05. This includes leap years; the calendar algorithm takes the presence of 29 February into account for leap years.

## DateDiff Function

## Microsoft.VisualBasic.DateAndTime

```
DateDiff(interval, date1, date2[, dayofweek[, weekofyear]])
```

*interval* required; String or DateInterval enum

Specifies the time unit used to express the difference between *date1* and *date2*

*date1*, *date2* required; Date or a literal date

The starting and ending dates, whose difference is computed as *date2* - *date1*

*dayofweek* optional; FirstDayOfWeek enum

A member of the FirstDayOfWeek enum

*weekofyear* optional; FirstWeekOfYear enum

A member of the FirstWeekOfYear enum

## Return Value

A Long specifying the number of time intervals between the two dates

## Description

Calculates the number of time intervals between two dates. For example, you can use the function to determine how

many days there are between 1 January 1980 and 31 May 1998.

*interval* can be one of the following literal strings:

|      |             |
|------|-------------|
| YYYY | Year        |
| q    | Quarter     |
| m    | Month       |
| y    | Day of year |
| d    | Day         |
| w    | Weekday     |
| ww   | Week        |
| h    | Hour        |
| n    | Minute      |
| s    | Second      |

*interval* can also be a member of the `DateInterval` enum:

```
Enum DateInterval
```

```
 Day
```

```
 DayOfYear
```

```
 Hour
```

```
 Minute
```

```
 Month
```

```
 Quarter
```

```
 Second
```

```
 Week
```

```
 Weekday
```

```
 WeekOfYear
```

```
End Enum
```

When *interval* is `Weekday` or "w", `DateDiff` returns the number of weeks between the two dates. If *date1* falls on a Monday, `DateDiff` counts the number of Mondays until *date2*. It counts *date2*, but not *date1*. If *interval* is `Week` or "ww", however, `DateDiff` returns the number of calendar weeks between the two dates. It counts the number of Sundays between *date1* and *date2*. `DateDiff` counts *date2* if it falls on a Sunday, but it doesn't count *date1*, even if it does fall on a Sunday.

## DatePart Function

## Microsoft.VisualBasic.DateAndTime

```
DatePart(interval, datevalue[, firstdayofweekvalue[, _
 firstweekofyearvalue]])
```

*interval* required; String or `DateInterval` enum

Defines the part of the date/time to extract from *datevalue*

*datevalue* required; Date, or an expression capable of conversion to a date

The Date value to evaluate

*firstdayofweekvalue* optional; FirstDayOfWeek enum

A member of the FirstDayOfWeek enum

*firstweekofyearvalue* optional; FirstWeekOfYear enum

A member of the FirstWeekOfYear enum

## Return Value

An Integer containing the specified part

## Description

Extracts an individual component of the date or time (like the month or the second) from a date/time value. The *DatePart* function returns an Integer containing the specified portion of the given date. *DatePart* is a single function encapsulating the individual *Year*, *Month*, *Day*, *Hour*, *Minute*, and *Second* functions.

*interval* can be one of the following literal strings:

|      |             |
|------|-------------|
| YYYY | Year        |
| q    | Quarter     |
| m    | Month       |
| y    | Day of year |
| d    | Day         |
| w    | Weekday     |
| ww   | Week        |
| h    | Hour        |
| n    | Minute      |
| s    | Second      |

*interval* can also be a member of the DateInterval enum:

Enum DateInterval

Day  
DayOfYear  
Hour  
Minute  
Month  
Quarter  
Second  
Week  
Weekday  
WeekOfYear

End Enum

The *firstdayofweekvalue* argument can be any of the following members of the `FirstDayOfWeek` enumeration:

```
Enum FirstDayOfWeek
 System 'uses first day of week
 'setting on local system
 Sunday
 Monday
 Tuesday
 Wednesday
 Thursday
 Friday
 Saturday
End Enum
```

The *firstdayofweekvalue* argument affects only calculations that use either the `Week` (or "w") or `Weekday` (or "ww") *interval* values.

The *firstweekofyearvalue* argument can be any of the following members of the `FirstWeekOfYear` enumeration:

| <b>FirstWeekOfYear constant</b> | <b>Value</b> | <b>Description</b>                                                     |
|---------------------------------|--------------|------------------------------------------------------------------------|
| <code>System</code>             | 0            | Uses the local system setting                                          |
| <code>Jan1</code>               | 1            | Starts with the week in which January 1 occurs (the default value)     |
| <code>FirstFourDays</code>      | 2            | Starts with the first week that has at least four days in the new year |
| <code>FirstFullWeek</code>      | 3            | Starts with the first full week of the year                            |

## **DateSerial Function**

## **Microsoft.VisualBasic.DateAndTime**

```
DateSerial(year, month, day)
```

*year* required; Integer

Number between 100 and 9999, inclusive, or a numeric expression

*month* required; Integer

Any numeric expression between 1 and 12 to express the month

*day* required; Integer

Any numeric expression between 1 and 31 to express the day

## **Return Value**

A Date representing the date specified by the arguments

## Description

Returns a Date whose value is specified by the three date components (year, month, and day).

For the function to succeed, all three components must be present, and all must be numeric values. The value returned by the function takes the short date format defined by the Regional Settings applet in the Control Panel of the client machine.

If the value of a particular element exceeds its normal limits, *DateSerial* adjusts the date accordingly. For example, `DateSerial(96,2,31)`-February 31, 1996-returns March 2, 1996.

You can specify expressions or formulas that evaluate to individual date components as parameters to *DateSerial*. For example, `DateSerial(98,10+9,23)` returns 23 March 1999. This makes it easier to use *DateSerial* to form dates whose individual elements are unknown at design time or that are created on the fly as a result of user input.

### DateString Property

### Microsoft.VisualBasic.DateAndTime

```
DateString()
```

## Return Value

A String representing the current system date in the format "mm-dd- yyyy"

## Description

Returns or sets a string representing the current system date. The allowed formats for setting the date are "m-d-yyyy," "m-d-y," "m/d/yyyy," and "m/d/y."

### Day Function

### Microsoft.VisualBasic.DateAndTime

```
Day(datevalue)
```

*datevalue* required; Date or literal date

Date whose day number is to be extracted

## Return Value

An Integer from 1 to 31, representing the day of the month

## Description

Returns an Integer ranging from 1 to 31, representing the day of the month of *datevalue*. The range of *datevalue* is 1/1/1 to 12/31/9999.

With `Option Strict On`, you must first convert *datevalue* to a Date data type before passing it to the *Day* function. You can use the *CDate* function for this purpose.

If the day portion of *datevalue* is outside of its valid range, the function generates an exception. This is also true if the day and month portion of *datevalue* is 2/29 for a non-leap year.

## GetTimer Function

Microsoft.VisualBasic.VBMath

---

`GetTimer( )`

### Return Value

A Double indicating the number of seconds

### Description

Returns the number of seconds since midnight.

## Hour Function

Microsoft.VisualBasic.DateAndTime

`Hour(timevalue)`

*timevalue* required; Date

Date variable or literal date whose hour component is to be extracted

### Return Value

An Integer from 0 to 23, specifying the hour of the day

### Description

Extracts the hour element from a time expression. Regardless of the time format passed to *Hour*, the return value will be a whole number between 0 and 23, representing the hour of a 24-hour clock. If *time* contains `Nothing`, 0 is returned, so be careful here to check for `Nothing`.

## Minute Function

Microsoft.VisualBasic.DateAndTime

`Minute(TimeValue)`

*TimeValue* required; Date

Date variable or literal date

## Return Value

An Integer between 0 and 59, representing the minute of the hour

## Description

Extracts the minute component from a given date/time expression

If *TimeValue* is not a valid date/time expression, the function generates an exception. To prevent this, use the *IsDate* function to check the argument before calling the *Minute* function. If *TimeValue* contains *Nothing*, 0 is returned, so be careful here to check for *Nothing*.

## Month Function

Microsoft.VisualBasic.DateAndTime

*Month(datevalue)*

*datevalue* required; Date

Date variable or literal date whose month component is to be extracted.

## Return Value

An Integer between 1 and 12

## Description

Returns an integer representing the month of the year of a given date expression. If *datevalue* contains *Nothing*, *Month* returns *Nothing*.

## MonthName Function

Microsoft.VisualBasic.DateAndTime

*MonthName(month [, abbreviate])*

*month* required; Integer

The ordinal number of the month, from 1 to 12

*abbreviate* optional; Boolean

A flag to indicate if an abbreviated month name should be returned

## Return Value

String containing the name of the specified month

## Description

Returns the month name of a given month. For example, a *month* of 1 returns January or (if *abbreviate* is `True`) Jan. The default value for *abbreviate* is `False`.

### Now Property

Microsoft.VisualBasic.DateAndTime

---

`Now( )`

## Return Value

A Date containing the current system date and time

## Description

Returns the current date and time based on the system setting. The date returned by `Now` takes the Windows General Date format based on the locale settings of the local computer. The U.S. setting for General Date is `mm/dd/yy hh:mm:ss`. The `Now` property is read-only.

### Second Function

Microsoft.VisualBasic.DateAndTime

`Second(timevalue)`

*timevalue* required; Date

Date variable or literal date

## Return Value

An Integer in the range 0 to 59, specifying the second in *timevalue*

## Description

Extracts the seconds from a given time expression. If the time expression time is `Nothing`, the *Second* function returns 0.

### TimeOfDay Property

Microsoft.VisualBasic.DateAndTime

TimeOfDay

## Return Value

Date value giving the current system time

## Description

Sets or returns the current system time.

## Timer Property

Microsoft.VisualBasic.DateAndTime

---

Timer

## Return Value

Double representing the number of seconds that have elapsed since midnight

## Description

Returns the number of seconds since midnight.

## TimeSerial Function

Microsoft.VisualBasic.DateAndTime

TimeSerial(*hour*, *minute*, *second*)

*hour* required; Integer

A number in the range 0 to 23

*minute* required; Integer

Any valid integer

*second* required; Integer

Any valid integer

## Return Value

A Date representing the time specified by the arguments to the function

## Description

Constructs a valid time given a number of hours, minutes, and seconds. Any of the arguments can be specified as relative values or expressions. The *hour* argument requires a 24-hour clock format; however, the returned time is determined by the system's regional settings.

If any value is greater than the normal range for the time unit to which it relates, the next higher time unit is increased accordingly. For example, a *second* argument of 125 will be evaluated as 2 minutes, 5 seconds.

If any value is less than zero, the next higher time unit is decreased accordingly. For example, `TimeSerial(2, -1, 30)` returns 01:59:30.

## TimeString Property

## Microsoft.VisualBasic.DateAndTime

```
TimeString()
```

### Return Value

String representing the current system time

### Description

The `TimeString` property returns the current system time in the format determined by the system's regional settings. You can use any time format recognized by *IsDate* when setting the time using the `TimeString` property.

The string returned by the `TimeString` property also includes an invalid date, 01/01/0001. It can be eliminated with the *Format* or *FormatDateTime* function as follows:

```
Format(TimeOfDay(), "Long Time")
FormatDateTime(TimeOfDay(), DateFormat.LongTime)
```

### TimeValue Function

See [TimeValue Function](#) entry under [Section 1.13](#).

## Weekday Function

## Microsoft.VisualBasic.DateAndTime

```
Weekday(datevalue, [dayofweek])
```

*date* required; Date or valid date expression

Any valid date expression

*dayofweek* optional; Constant of `FirstDayOfWeek` enumeration

A constant indicating the first day of the week

## Return Value

Integer

## Description

Determines the day of the week of a given date. The default for *dayofweek* is `FirstDayOfWeek.Sunday`.

To determine the day of the week, think of the day specified by *dayofweek* as day 1, and the value returned by the function as indicating the day relative to day 1. Then, for example, if the return value of *WeekDay* is 2, this specifies the day following *dayofweek*. A return value of 1 specifies *dayofweek*. A return value of 7 specifies the day before *dayofweek*.

The members of the `FirstDayOfWeek` enumeration are:

| Constant  | Value | Description |
|-----------|-------|-------------|
| Sunday    | 1     | Sunday      |
| Monday    | 2     | Monday      |
| Tuesday   | 3     | Tuesday     |
| Wednesday | 3     | Wednesday   |
| Thursday  | 4     | Thursday    |
| Friday    | 5     | Friday      |
| Saturday  | 6     | Saturday    |
| Sunday    | 7     | Sunday      |

Passing a value of 0 as the *dayofweek* argument uses the system's locale settings to determine the first day of the week.

## WeekdayName Function

## Microsoft.VisualBasic.DateAndTime

`WeekdayName(Weekday, [abbreviate [, FirstDayOfWeekValue]])`

*Weekday* required; Long

The ordinal number of the required weekday, from 1 to 7

*abbreviate* optional; Boolean

Specifies whether to return the full day name or an abbreviation

*FirstDayOfWeekValue* optional; `FirstDayOfWeek` constant

Member of the `FirstDayOfWeek` enum indicating the first day of the week

## Return Value

A String

## Description

Returns the name of the day. *Weekday* must be a number between 1 and 7, or the function generates an `ArgumentException` error.

The default value of *abbreviate* is `False`. For a list of the members of the `FirstDayOfWeek` enumeration, see the "Weekday Function" entry. The default value of *FirstDayOfWeekValue* is `FirstDayOfWeek.Monday`.

## Year Function

## Microsoft.VisualBasic.DateAndTime

---

`Year(datevalue)`

*datevalue* required; Date or valid date expression

Any valid date expression

## Return Value

Integer

## Description

Returns an integer representing the year in a given date expression. If `OptionStrict` is off and *datevalue* contains `Nothing`, *Year* returns 1. For example:

```
Dim oDat As Object
Console.WriteLine(Year(sDat)) ' Displays 1
```

If *datevalue* is a date literal (a date delimited with the # symbol), the year must contain four digits.

## 1.16 Declaration

### Class . . . End Class Statement

---

```
[accessmodifier] [Shadows] [inheritability] Class Name
 statements
End Class
```

*accessmodifier* optional; Keyword

The possible values of *accessmodifier* are `Public`, `Private`, and `Friend`

*Shadows* optional; Keyword

Indicates that the *Name* class shadows any element of this same name in a base class

*inheritability* optional; Keyword

One of the keywords, `MustInherit` or `NotInheritable`, must be used. `MustInherit` specifies that objects of this class cannot be created, but that objects of derived classes can be created. `NotInheritable` specifies that this class cannot be used as a base class

*Name* required; String literal

The name of the class

### Description

Defines a class and delimits the statements that define that class' variables, properties, and methods.

If the `Inherits` or `Implements` statements appear in a class module, they must appear before any other statements in the module. Moreover, the `Inherits` keyword must appear before the `Implements` keyword.

Within a class code block, members are declared as `Public`, `Private`, `Protected`, `Friend`, or `Protected Friend`. The `Dim` keyword is equivalent to `Private` when used in class modules (but it is equivalent to `Public` in structures). Property declarations are automatically `Public`.

The `Class . . . End Class` construct can include the following elements:

*Private variable or procedure declarations*

These items are accessible within the class but do not have scope outside of the class.

*Public variable or procedure declarations*

`Public` variables are public properties of the class; `Public` procedures are public methods of the class.

### Property declarations

These are the public properties of the class. Default properties can be declared by using the `Default` keyword.

## Const Statement

---

```
[accessmodifier] Const constantname [As type] = constantvalue
accessmodifier optional; Keyword
```

One of the keywords `Public`, `Private`, `Protected`, `Friend`, or `Protected Friend`.

*constantname* required; String Literal

The name of the constant.

*type* optional; Keyword

The data type; it can be `Byte`, `Boolean`, `Char`, `Short`, `Integer`, `Long`, `Single`, `Double`, `Decimal`, `Date`, or `String`, as well as any of the data types defined in the Base Class Library.

*constantvalue* required; Numeric or String

A literal, constant, or any combination of literals and constants that includes arithmetic or logical operators, except `Is`.

## Description

Associates a constant value with a name. This feature is provided to make code more readable. The name is referred to as a *symbolic constant*.

If `Option Strict` is on, the data type of the constant must be defined by using the `As type` clause.

## Declare Statement

*Syntax for subroutines:*

```
[accessmodifier] Declare [Ansi|Unicode|Auto] Sub name_
 Lib "libname" [Alias "aliasname"] ([arglist])
```

*Syntax for functions:*

```
[accessmodifier] Declare [Ansi|Unicode|Auto] Function name _
 Lib "libname" [Alias "aliasname"] ([arglist]) [As type]
```

*accessmodifier* optional; Keyword

*accessmodifier* can be any one of the following: `Public`, `Private`, `Protected`, `Friend`, or

**Protected Friend.** The following table describes the effects of the various access modifiers. Note that *direct access* refers to accessing the member without any qualification, as in:

```
classvariable = 100
```

and *class/object access* refers to accessing the member through qualification, either with the class name or the name of an object of that class.

|                  | Direct access scope        | Class/objectaccess scope |
|------------------|----------------------------|--------------------------|
| Private          | Declaring class            | Declaring class          |
| Protected        | All derived classes        | Declaring class          |
| Friend           | Derived in-project classes | Declaring project        |
| Protected Friend | All derived classes        | Declaring project        |
| Public           | All derived classes        | All projects             |

**Ansi** optional; Keyword

Converts all strings to ANSI values.

**Unicode** optional; Keyword

Converts all strings to Unicode values.

**Auto** optional; Keyword

Converts the strings according to .NET rules based on the name of the method (or the alias name, if specified). If no modifier is specified, **Auto** is the default.

*name* required; String literal

Any valid procedure name. Note that DLL entry points are case sensitive. If the *aliasname* argument is used, *name* represents the name by which the function or procedure is referenced in your code, while *aliasname* represents the name of the routine as found in the DLL.

**Lib** required; Keyword

Indicates that a DLL or code resource contains the procedure being declared.

*libname* required; String literal

Name of the DLL or code resource that contains the declared procedure.

**Alias** optional; Keyword

Indicates that the procedure being called has another name in the DLL. This is useful when the external procedure name is the same as a keyword. You can also use **Alias** when a DLL procedure has the same name as a public variable, constant, or any other procedure in the same scope. **Alias** is also useful if any characters in the DLL procedure name aren't allowed by VB.NET naming conventions.

*aliasname* optional; String literal

Name of the procedure in the DLL or code resource. If the first character is not a number sign (#), *aliasname* is the name of the procedure's entry point in the DLL. If # is the first character, all characters that follow must indicate the ordinal number of the procedure's entry point.

*arglist* optional

List of variables representing arguments that are passed to the procedure when it is called.

*type* optional; Keyword

Data type of the value returned by a Function procedure; may be `Byte`, `Boolean`, `Char`, `Short`, `Integer`, `Long`, `Single`, `Double`, `Decimal`, `Date`, `String`, `Object`, or any user-defined type. Arrays of any type cannot be returned, but an `Object` containing an array can.

## Description

Used at module level to declare references to external procedures in a dynamic-link library (DLL).

The data type you use in the `As` clause following *arglist* must match that returned by the function.

## Dim Statement

```
[Shared] [Shadows] [readonly] Dim_
[WithEvents] varname([subscripts])_
[As [New] type] [= initexpr]
```

`Shared` optional; Keyword

Indicates the variable is not associated with any particular class instance but is accessible directly using the class name and is therefore "shared" by all class instances.

`Shadows` optional; Keyword

Indicates that the variable shadows any programming elements (variables, procedures, enums, constants, etc.) of the same name in a base class.

`WithEvents` optional; Keyword

In an object variable definition, indicates that the object will receive event notification

*varname* required

The name of the variable

*subscripts* optional

Dimensions of an array variable

`New` optional; Keyword

Keyword that creates an instance of an object

*type* optional unless `Option Strict is On`

The data type of *varname*

*initexpr* optional

Any expression that provides the initial value to assign to the variable; cannot be used if an `As New` clause is used

## Description

Declares and allocates storage space in memory for variables. The `Dim` statement is used either at the start of a procedure or the start of a module to declare a variable of a particular data type.

`Object` is the default data type created when no data type is explicitly declared.

The declaration of a nonobject variable actually creates the variable. For an object variable, the variable is not created unless the optional `New` statement is used. If not, then the object variable is set to `Nothing` and must be assigned a reference to an existing object at some later point in the code.

Variables that are not explicitly initialized by the `Dim` statement have the following default values:

| Data type         | Initial value          |
|-------------------|------------------------|
| All numeric types | 0                      |
| Boolean           | False                  |
| Date              | 01/01/0001 12:00:00 AM |
| Decimal           | 0                      |
| Object            | Nothing                |
| String            | Nothing                |

## Enum Statement

```
accessmodifier Enum name [As type]
 membername [= constantexpression]
 membername [= constantexpression]
 ...
End Enum
```

*accessmodifier* optional; Keyword

Possible values are `Public`, `Private`, `Friend`, `Protected`, or `Protected Friend`

*name* required; String literal

The name of the enumerated data type

*membername* required; String literal

The name of a member of the enumerated data type

*constantexpression* optional; Long

The value to be assigned to *membername*

*type* optional; Keyword

The data type of the enumeration. All enumerated members must be integers; possible values are `Byte`, `Short`, `Integer`, and `Long`

## Description

Defines an enumerated data type. All of the values of the data type are defined by the instances of *membername*.

## Friend Keyword

## Description

The `Friend` keyword is used to declare classes, module-level variables (but not local variables), constants, enumerations, properties, methods, functions, and subroutines.

When the `Friend` keyword is used, the item being declared has direct access scope inside of the class module in which the item is declared, as well as in all derived classes in the same project. However, if the item is declared using `Protected Friend`, then the scope is all derived classes, including those that are in other projects.

## Function Statement

```
[ClassBehavior][AccessModifier] Function name _
 [(arglist)] [As type][()]
 [statements]
 [name = expression]
 [statements]
End Function
ClassBehavior optional; Keyword
```

One of the following keywords:

### Overloads

Indicates that more than one declaration of this function (with different argument signatures) exists.

### Overrides

For derived classes, indicates that the function overrides the function by the same name (and argument signature) in the base class.

### Overridable

Indicates that the function can be overridden in a derived class.

### NotOverridable

Indicates that the function cannot be overridden in a derived class.

### MustOverride

Indicates that the function must be overridden in a derived class.

### Shadows

In a derived class definition, indicates that this element shadows any elements of the same name in the base class.

### Shared

Makes the function callable without creating an object of the class. It is, in this strange sense, shared by all objects of the class. These are also called static functions.

### *AccessModifier* optional; Keyword

One of the following keywords: `Public`, `Private`, `Protected`, `Friend`, `Protected Friend`. The following table describes the effects of the various access modifiers. Note that direct access refers to accessing the member without any qualification, as in:

```
classvariable = 100
```

and class/object access refers to accessing the member through qualification, either with the class name or the name of an object of that class:

|                               | Direct access scope        | Class/objectaccess scope |
|-------------------------------|----------------------------|--------------------------|
| <code>Private</code>          | Declaring class            | Declaring class          |
| <code>Protected</code>        | All derived classes        | Declaring class          |
| <code>Friend</code>           | Derived in-project classes | Declaring project        |
| <code>Protected Friend</code> | All derived classes        | Declaring project        |
| <code>Public</code>           | All derived classes        | All projects             |

*name required; String literal*

The name of the function.

*arglist* optional

A comma-delimited list of variables to be passed to the function as arguments from the calling procedure.

*arglist* uses the following syntax and parts:

```
[Optional] [ByVal | ByRef] [ParamArray] varname[()]_
[As type] [= defaultvalue]
Optional optional; Keyword
```

An optional argument is one that need not be supplied when calling the function. However, all arguments following an optional one must also be optional. A `ParamArray` argument cannot be optional.

`ByVal` optional; Keyword

The argument is passed by value; that is, the local copy of the variable is assigned the value of the argument. `ByVal` is the default method of passing variables.

`ByRef` optional; Keyword

The argument is passed by reference; that is, the local variable is simply a reference to the argument being passed. All changes made to the local variable will be also reflected in the calling argument.

`ParamArray` optional; Keyword

Indicates that the argument is an optional array of Objects (or a strongly typed array, if `Option Strict` is on) containing an arbitrary number of elements. It can only be used as the last element of the argument list and cannot be used with the `ByRef` or `Optional` keywords.

*varname* required; String literal

The name of the local variable containing either the reference or value of the argument.

*type* optional; Keyword

The data type of the argument.

*defaultvalue* optional; String literal

For optional arguments, you must specify a default value.

*type* optional; Keyword

The return data type of the function.

*statements* optional

Program code to be executed within the function.

*expression* optional

The value to return from the function to the calling procedure.

## Description

Defines a function procedure.

If you do not include one of the `access` keywords, a function will be `Public` by default.

## Option Explicit Statement

---

```
Option Explicit [On | Off]
```

## Description

Use `Option Explicit` to generate a compile-time error whenever a variable that has not been declared is encountered.

In modules where the `Option Explicit` statement is not used, any undeclared variables are automatically cast as Objects.

The default is `Option Explicit On`. In other words, the statement:

```
Option Explicit
```

is equivalent to:

```
Option Explicit On
```

## Private Statement

```
Private [WithEvents] varname ([subscripts]) [As [New] type] _
[, [WithEvents] varname ([subscripts]) [As [New] type]] ...
```

`WithEvents` optional; Keyword

A keyword that denotes the object variable, *varname*, can respond to events triggered from within the object to which it refers

*varname* required; any

The name of the variable, following Visual Basic naming conventions

*subscripts* optional; Integer or Long

Denotes *varname* as an array and specifies the number and extent of array dimensions

New optional; Keyword

Used to automatically create an instance of the object referred to by the *varname* object variable

*type* optional; Keyword

Data type of the variable *varname*

## Description

Used at module level to declare a private variable and allocate the relevant storage space in memory. `Private` can also be used with procedures and class modules.

## Property Statement

---

```
[Default] [accessmodifier] [ReadOnly| WriteOnly] _
 [ClassBehavior] Property name _
 [(arglist)] [As type] [Implements interfacemember]
Get
 [statements]
End Get
Set
 [statements]
End Set
End Property
```

Default optional; Keyword

Specifies that the property is the default property. Must have both a Get and a Set block.

accessmodifier optional; Keyword

One of the keywords `Public`, `Private`, `Protected`, `Friend`, or `Protected Friend`.

ReadOnly optional; Keyword

Indicates that the property is read-only. Must have only a Get block. (If you try to write a Set block, VB will generate a compiler error.)

WriteOnly optional; Keyword

Indicates that the property is write-only. Must have only a Set block. (If you try to write a Get block, VB will generate a compiler error.)

*ClassBehavior* optional; Keyword

One of the following keywords:

### Overloads

Indicates that more than one declaration of this function (with different argument signatures) exists.

### Overrides

For derived classes, indicates that the function overrides the function by the same name (and argument signature) in the base class.

### Overridable

Indicates that the function can be overridden in a derived class.

### NotOverridable

Indicates that the function cannot be overridden in a derived class.

### MustOverride

Indicates that the function must be overridden in a derived class.

### Shadows optional; Keyword

Indicates that the property shadows any element of this same name in a base class.

### Shared

Makes the function callable without creating an object of the class. It is, in this strange sense, shared by all objects of the class. These are also called static functions.

### *name* required; String literal

The name of the property.

### *arglist* optional; any

A comma-delimited list of variables to be passed to the property as arguments from the calling procedure.

### *type* optional

The return data type of the property. The default is Object.

### Implements *interfacename* optional

Indicates that the property implements a property by the same name in the interface named *interfacename*.

## Description

Declares a class property.

`Overloads` and `Shadows` cannot be used in the same property declaration.

Property procedures are `Public` by default.

The `Friend` keyword is only valid within class modules. `Friend` properties are accessible to all procedures in all modules and classes within a project, but are not listed in the class library for that project. Therefore, they cannot be accessed from projects or applications outside the defining application.

Properties and procedures defined using the `Friend` keyword cannot be late bound.

The `Default` keyword can be used only in the case of parameterized properties. Typically, these are properties that either return collection objects or are implemented as property arrays.

## Protected Keyword

---

### Description

Used to declare classes and their members.

When the `Protected` keyword is used to modify a member declaration, the member being declared has direct access scope to the class module in which the member is declared, as well as to all derived classes in all projects. However, as far as object access is concerned, the member is considered `Private`; that is, it can only be accessed within the declaring class.

Declaring a class module as `Protected` limits all of the class' members to Protected access (or stronger if the member has further specific access restrictions).

### Public Statement

```
[Overrides] [Shadows] Public [WithEvents] _
 varname([subscripts]) [As [New] type] [, [WithEvents] _
 varname([subscripts]) [As [New] type]] ...
```

`Overrides` optional; Keyword

In a derived class definition, indicates that a variable overrides a similar variable in a base class

`Shadows` optional; Keyword

In a derived class definition, indicates that calls to derived class members that are made through a base class ignore the shadowed implementation

`WithEvents` optional; Keyword

A keyword that denotes the object variable, *varname*, can respond to events triggered from within the object to which it refers

*varname* required; String literal

The name of the variable, which must follow Visual Basic naming conventions

*subscripts* optional; Numeric constant or literal

Denotes *varname* as an array and specifies the dimensions and number of elements of the array

New optional; Keyword

Used to automatically create an instance of the object referred to by the *varname* object variable

*type* optional

Data type of the variable *varname*

## Description

Used at module level to declare a public variable and allocate the relevant storage space in memory.

A Public variable has both project-level scope-that is, it can be used by all procedures in all modules in the project-and, when used in a Class module, it can have scope outside the project.

The `Public` keyword also applies to procedures and class modules.

The behavior of a Public variable depends on where it is declared, as the following table shows:

| Variable declared in . . .        | Scope                                                                                                                               |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| A procedure                       | Illegal-this generates a compile-time error.                                                                                        |
| Code module declarations section  | Variable is available to all modules within the project.                                                                            |
| Class module declarations section | Variable is available as a property of the class to all modules within the project and to all other projects referencing the class. |
| Form module declarations section  | Variable is available as a property of the form to all modules within the project.                                                  |

## Static Statement

```
Static varname([subscripts]) [As [New] type] _
 [,varname([subscripts]) [As [New] type]] ...
```

*varname* required; any

The name of the variable, following Visual Basic naming conventions

*subscripts* optional; Integer

Denotes *varname* as an array and specifies the dimension and upper bounds of the array

New optional; Keyword

Used to automatically create an instance of the object referred to by the object variable *varname*

*type* optional; Keyword

Data type of the variable *varname*

## Description

Used at procedure level to declare a Static variable and to allocate the relevant storage space in memory. Static variables retain their value between calls to the procedure in which they are declared.

### Structure...End Structure Statement

```
accessmodifier Structure StructureName
 [Implements interfacenames]
 variable declarations
 procedure declarations
End Structure
```

*accessmodifier* optional; Keyword

The possible values of *accessmodifier* are Public, Private, Friend, Protected, Protected Friend.

Implements *interfacenames* optional

Indicates that the structure implements the members of one or more interfaces

## Description

Used to declare user-defined types. Structures are similar to classes, but they are value types rather than reference types.

### Sub Statement

```
[ClassBehavior] [AccessModifier] Sub name [(arglist)]
 [statements]
[Exit Sub]
 [statements]
End Sub
```

*ClassBehavior* optional; Keyword

One of the keywords shown in the following table:

| Keyword        | Description                                                                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Overloads      | Indicates that more than one declaration of this subroutine exists (with different argument signatures).                                                              |
| Overrides      | For derived classes, indicates that the subroutine overrides the subroutine by the same name (and argument signature) in the base class.                              |
| Overridable    | Indicates that the subroutine can be overridden in a derived class.                                                                                                   |
| NotOverridable | Indicates that the subroutine cannot be overridden in a derived class.                                                                                                |
| MustOverride   | Indicates that the subroutine must be overridden in a derived class.                                                                                                  |
| Shadows        | In a derived class definition, indicates that calls to derived class members that are made through a base class ignore the shadowed implementation.                   |
| Shared         | Callable without creating an object of the class. It is, in this strange sense, shared by all objects of the class. These are also called <i>static subroutines</i> . |

*AccessModifier* optional

Possible values are `Public`, `Private`, `Friend`, `Protected`, or `Protected Friend`. The following table describes the effects of the various access modifiers. Note that "direct access" refers to accessing the member without any qualification, as in:

```
classvariable = 100
```

and "class/object access" refers to accessing the member through qualification, either with the class name or the name of an object of that class.

|                               | Direct access scope        | Class/objectaccess scope |
|-------------------------------|----------------------------|--------------------------|
| <code>Private</code>          | Declaring class            | Declaring class          |
| <code>Protected</code>        | All derived classes        | Declaring class          |
| <code>Friend</code>           | Derived in-project classes | Declaring project        |
| <code>Protected Friend</code> | All derived classes        | Declaring project        |
| <code>Public</code>           | All derived classes        | All projects             |

*name* required; String literal

The name of the Sub procedure.

*arglist* optional; any

A comma-delimited list of variables to be passed to the sub procedure as arguments from the calling

procedure.

*arglist* uses the following syntax and parts:

```
[Optional] [ByVal | ByRef] [ParamArray] varname[()] _
 [As type] [= defaultvalue]
Optional optional; Keyword
```

An optional argument is one that need not be supplied when calling the function. However, all arguments following an optional one must also be optional. A `ParamArray` argument cannot be optional.

`ByVal` optional; Keyword

The argument is passed by value; that is, the local copy of the variable is assigned the value of the argument. `ByVal` is the default method of passing variables.

`ByRef` optional; Keyword

The argument is passed by reference; that is, the local variable is simply a reference to the argument being passed. All changes made to the local variable will be reflected in the calling argument.

`ParamArray` optional; Keyword

Indicates that the argument is an optional array containing an arbitrary number of elements. It can only be used as the last element of the argument list, and cannot be modified by either the `ByRef` or `Optional` keywords. If `Option Strict` is on, the array type must also be specified.

*varname* required; String literal

The name of the local variable containing either the reference or value of the argument.

*type* optional; Keyword

The data type of the argument. It can be Boolean, Byte, Char, Date, Decimal, Double, Integer, Long, Object, Short, Single, String, a user- defined type, or an object type.

*defaultvalue* optional; any

For optional arguments, you must specify a default value.

*statements* optional

Program code to be executed within the procedure.

## Description

Defines a subroutine.

If you do not include one of the *accessmodifier* keywords, a subroutine will be `Public` by default.

## 1.17 Error Handling

### Err Property

Microsoft.VisualBasic.Information

---

`Err`

### Return Value

An Integer containing the line number

### Description

Indicates the line number on which an error occurred.

### Err.Clear Method

Microsoft.VisualBasic.ErrObject

`Err.Clear( )`

### Description

Explicitly resets all the properties of the Err object after an error has been handled.

### Err.Description Property

Microsoft.VisualBasic.ErrObject

`Err.Description = string`  
`string = Err.Description`  
*string* required; String

*To set the property*  
*To return the property value*

Any string expression

### Description

A read/write property containing a short string describing a runtime error.

### Err.GetException Method

Microsoft.VisualBasic.ErrObject

```
Err.GetException()
```

## Return Value

A `System.Exception` object or an object inherited from it containing the current exception

## Description

Returns the Exception object associated with the current error.

### **Err.HelpContext Property**

**Microsoft.VisualBasic.ErrObject**

---

```
Err.HelpContext
```

## Description

A read/write property that either sets or returns an Integer value containing the context ID of the appropriate topic within a Help file.

### **Err.HelpFile Property**

**Microsoft.VisualBasic.ErrObject**

```
Err.HelpFile
```

## Description

A read/write String property that contains the fully qualified path of a Windows Help file.

### **Err.LastDLLError Property**

**Microsoft.VisualBasic.ErrObject**

```
Err.LastDLLError
```

## Description

A read-only property containing a system error code representing a system error produced within a DLL called from a VB program.

### **Err.Number Property**

**Microsoft.VisualBasic.ErrObject**

`Err.Number`

## Description

A read/write property containing a numeric value that represents the error code for the last error generated.

## Err.Raise Method

## Microsoft.VisualBasic.ErrObject

---

`Err.Raise(number, source, description, helpfile, helpcontext)`

*number* required; Long integer

A numeric identifier of the particular error

*source* optional; String

The name of the object or application responsible for generating the error

*description* optional; String

A useful description of the error

*helpfile* optional; String

The fully qualified path of a Microsoft Windows Help file containing help or reference material about the error

*helpcontext* optional; Long

The context ID within *helpfile*

## Description

Generates a runtime error.

## Err.Source Property

## Microsoft.VisualBasic.ErrObject

`Err.Source`

## Description

A read/write string property containing the name of the application or the object that has generated the error.

## ErrorToString Function

## Microsoft.VisualBasic.Conversion

---

```
ErrorToString([errornumber])
```

*errornumber* optional; Long

A numeric error code

## Return Value

A String containing an error message

## Description

Returns the error message or error description corresponding to a particular error code.

## IsError Function

Microsoft.VisualBasic.Information

---

```
IsError(expression)
```

*expression* required; Object

An object variable that may be an Exception object

## Return Value

Boolean (True if *expression* is an Exception object, False otherwise)

## Description

Indicates whether an object is an instance of the Exception class or one of its derived classes.

## On Error Statement

```
On Error GoTo label | 0 | -1 Syntax 1.
```

```
On Error Resume Next Syntax 2.
```

*label* Either *label*, 0, or -1 is required

A valid label within the subroutine

## Description

Enables or disables error handling within a procedure.

If you don't use an `On Error` statement or a `Try...Catch` block in your procedure, or if you have explicitly switched off error handling, the Visual Basic runtime engine will automatically handle the error. First, it will display a dialog box containing the standard text of the error message. Second, it will terminate the application. So any error that occurs in the procedure will produce a fatal runtime error.

## Resume Statement

---

```
Resume [0]
Resume Next
Resume label
```

### Description

Used to continue program execution when an error-handling routine is complete.

## Throw Statement

```
Throw exception
exception required; System Exception or a derived type
```

An Exception object representing the exception being thrown

### Description

Throws an exception that can be handled using either structured exception handling (a `Try...Catch` block) or unstructured exception handling (the `On Error` statement).

## Try...Catch...Finally Statement

```

Try
 tryStatements
[Catch1 [exception [As type]] [When expression]
 catchStatements1
[Exit Try]

Catch2 [exception [As type]] [When expression]
 catchStatements2
[Exit Try]
...
Catchn [exception [As type]] [When expression]
 catchStatementsn]
[Exit Try]

[Finally
 finallyStatements]
End Try

```

*exception* optional; System.Exception or a derived type

The exception to catch. If *exception* is omitted or if it is `System.Exception`, all exceptions will be caught. However, if *exception* is omitted, no information about the exception will be accessible within the `Catch` block.

*type* optional

The data type of the exception to be handled by the `Catch` block. Its value can be `System.Exception` or any derived type. If omitted, its value defaults to `System.Exception`, and all exceptions will be handled.

*expression* optional; Boolean

A logical expression that defines a condition under which the error is to be handled by the `Catch` block.

## Description

Handles runtime errors using Structured Exception Handling.

The *tryStatements*, which are required, constitute the `Try` block and are the statements that VB monitors for errors.

The `Catch` blocks, of which there can be more than one, contain code that is executed in response to VB "catching" a particular type of error within the `Try` block. Thus, the `Catch` blocks consist of the error-handlers for the `Try` block.

The phrases *exception [As type]* and *[When expression]* are referred to as *filters* in the VB.NET documentation. In the former case, *exception* is either a variable of type `Exception`, which is the base class that "catches" all exceptions, or a variable of one of `Exception`'s derived classes. The `When` filter is typically used with

user-defined errors.

The `Exit Try` statement is used to break out of any portion of a `Try...Catch...Finally` block.

The optional `finallyStatements` code block is executed regardless of whether an error occurs (or is caught), unless an `Exit Try` statement is executed.

Multiple `Catch` statements can be used. However, only the first `Catch` statement to be true is executed. This means that multiple `Catch` statements should be ordered from most specific to most general, with a `Catch` block handling errors of type `System.Exception` occurring last.

## 1.18 Filesystem

### ChDir Procedure

Microsoft.VisualBasic.FileSystem

---

`ChDir(path)`

*path* required; String

The path of the directory to set as the new default directory

#### Description

Changes the current working (default) directory.

### ChDrive Procedure

Microsoft.VisualBasic.FileSystem

`ChDrive(drive)`

*drive* required; String or Char

The letter of the drive (A-Z) to set as the new default drive

#### Description

Changes the current working (default) disk drive.

### CurDir Function

Microsoft.VisualBasic.FileSystem

`CurDir[(drive)]`

*drive* optional; String or Char

The name of the drive

#### Return Value

A String containing the current path

#### Description

Returns the current directory of a particular drive or the default drive.

If no drive is specified or if *drive* is a zero-length string (""), *CurDir* returns the path for the current drive.

*drive* can be the single-letter drive name with or without a colon (i.e., both "C" and "C:" are valid values for *drive*).

If *drive* is invalid, the function will generate an *IOException* exception.

Because *CurDir* can only accept a single-character string, you cannot use network drive names, share names, or UNC drive names.

## Dir Function

## Microsoft.VisualBasic.FileSystem

```
Dir[(pathname[, attributes])]
```

*pathname* optional; String

A string expression that defines a path, which may contain a drive name, a folder name, and a filename

*attributes* optional; Numeric or Constant of the `FileAttribute` enumeration

The file attributes to be matched

## Return Value

String

## Description

Returns the name of a single file or folder matching the pattern and attribute passed to the function.

A zero-length string ("") is returned if a matching file is not found.

Possible values for *attributes* are:

| FileAttributeenumeration | Value | Description                                                  |
|--------------------------|-------|--------------------------------------------------------------|
| Normal                   | 0     | Normal (not hidden and not a system file)                    |
| ReadOnly                 | 1     | Read-only file                                               |
| Hidden                   | 2     | Hidden                                                       |
| System                   | 4     | System file                                                  |
| Volume                   | 8     | Volume label; if specified, all other attributes are ignored |
| Directory                | 16    | Directory or folder                                          |
| Archive                  | 32    | Archive                                                      |
| Alias                    | 64    | Alias or link                                                |

## FileCopy Procedure

Microsoft.VisualBasic.FileSystem

---

`FileCopy(source, destination)`

*source* required; String

The name of the source file to be copied

*destination* required; String

The name and location of the file when copied

### Return Value

None

### Description

Copies a file.

## FileDateTime Function

Microsoft.VisualBasic.FileSystem

`FileDateTime(pathname)`

*pathname* required; String

The filename, along with an optional drive and path

### Return Value

A Date containing the date and time at which the specified file was created or last modified

### Description

Obtains the date and time at which a particular file was created or last modified (whichever is later).

## GetAttr Function

Microsoft.VisualBasic.FileSystem

`GetAttr(pathname)`

*pathname* required; String

Filename and an optional pathname

## Return Value

An integer representing the sum of the following constants or members of the `FileAttribute` enumeration, which reflect the attributes set for the file:

| FileAttribute Numeration | Constant                 | Value | Description                        |
|--------------------------|--------------------------|-------|------------------------------------|
| Normal                   | <code>VbNormal</code>    | 0     | Normal                             |
| ReadOnly                 | <code>VbReadOnly</code>  | 1     | Read-only                          |
| Hidden                   | <code>VbHidden</code>    | 2     | Hidden                             |
| System                   | <code>VbSystem</code>    | 4     | System                             |
| Directory                | <code>VbDirectory</code> | 16    | Directory or folder                |
| Archive                  | <code>VbArchive</code>   | 32    | File has changed since last backup |

## Description

Determines which attributes have been set for a file or directory

### Kill Procedure

**Microsoft.VisualBasic.FileSystem**

```
Kill(pathname)
```

*pathname* required; String

The file or files to be deleted

## Description

Deletes a file from disk. The ? and \* wildcard characters can be used to specify multiple files.

### MkDir Procedure

**Microsoft.VisualBasic.FileSystem**

```
MkDir(path)
```

*path* required; String

The name of the folder to be created

## Description

Creates a new folder.

### Rename Procedure

**Microsoft.VisualBasic.FileSystem**

```
Rename(oldpath, newpath)
```

*oldpath* required; String

The current filename and optional path

*newpath* required; String

The new filename and optional path

## Description

Renames a disk file or folder.

### Rmdir Procedure

Microsoft.VisualBasic.FileSystem

---

```
Rmdir(path)
```

*path* required; String

The path of the folder to be removed

## Description

Removes a folder.

### SetAttr Procedure

Microsoft.VisualBasic.FileSystem

```
SetAttr(pathname, attributes)
```

*pathname* required; String

The name of the file or directory whose attributes are to be set

*attributes* required; FileAttribute enumeration

Numeric expression, FileAttribute enumerated constant, or global VB constant specifying the attributes

## Description

Changes the attribute properties of a file.

You can use any sum of the following constants to set the attributes of a file:

| Constant   | Value | Description                        |
|------------|-------|------------------------------------|
| VbNormal   | 0     | Normal                             |
| VbReadOnly | 1     | Read-only                          |
| VbHidden   | 2     | Hidden                             |
| VbSystem   | 4     | System                             |
| VbArchive  | 32    | File has changed since last backup |

Each global constant has a corresponding constant in the `FileAttribute` enumeration. For example, `vbNormal` is identical to `FileAttribute.Normal`. The file-attribute constants `vbDirectory`, `vbAlias`, and `vbVolume` cannot be used when assigning attributes.

File-attributes constants can be `Or`d to set more than one attribute at the same time. For example:

```
SetAttr "SysFile.Dat", FileAttribute.System Or FileAttribute.Hidden
```

## Unlock Procedure

## Microsoft.VisualBasic.FileSystem

```
Unlock(filenumber[, record])
Unlock(filenumber[, fromrecord[, torecord]])
```

*filenumber* required; Integer

Any valid file number

*record* required; Long

The record or byte number at which to commence the lock

*fromrecord* required; Long

The first record or byte number to lock

*torecord* required; Long

The last record or byte number to lock

## Description

Use the `Unlock` procedure in situations where more than one part of your program may need read and write access to the same data file. The `Unlock` procedure removes a lock that the `Lock` procedure placed on a section of the file or the whole file.

## Write Procedure

## Microsoft.VisualBasic.FileSystem

```
Write(filenumber, output)
```

*filenumber* required; Integer

Any valid file number

*output* required; Object (any)

A comma-delimited list of expressions or a ParamArray to be written to the file.

## Named Arguments

No

## Description

Writes data to a sequential file

### WriteLine Procedure

### Microsoft.VisualBasic.FileSystem

---

```
WriteLine(filenumber, [output])
```

*filenumber* required; Integer

Any valid file number

*output* optional; Object (any)

A comma-delimited list of expressions or a ParamArray to be written to the file

## Named Arguments

No

## Description

Writes data to a sequential file and then adds a line-feed character combination

## 1.19 Financial

### DDB Function

Microsoft.VisualBasic.Financial

---

`DDB(cost, salvage, life, period[, factor])`

*cost* required; Double

The initial cost of the asset

*salvage* required; Double

The value of the asset at the end of *life*

*life* required; Double

Length of life of the asset

*period* required; Double

Period for which the depreciation is to be calculated

*factor* optional; Double

The rate at which the asset balance declines. If omitted, 2 (double-declining method) is assumed; however, the documentation doesn't mention what other values are supported or what they mean

### Return Value

Double representing the depreciation of an asset

### Description

Returns a Double representing the depreciation of an asset for a specific time period. This is done using the double-declining balance method or another method that you specify using the *factor* argument.

The double-declining balance calculates depreciation at a differential rate, which varies inversely with the age of the asset. Depreciation is highest at the beginning of an asset's life and declines over time.

### FV Function

Microsoft.VisualBasic.Financial

`FV(rate, nper, pmt[, pv [, due]])`

*rate* required; Double

The interest rate per period

*nper* required; Integer

The number of payment periods in the annuity

*pmt* required; Double

The payment made in each period

*pv* optional; Variant

The present value of the loan or annuity

*due* optional; Constant of the `DueDate` enumeration

Specifies whether payments are due at the start or the end of the period. The value can be `DueDate.BegOfPeriod` or `DueDate.EndOfPeriod` (the default).

## Return Value

A Double specifying the future value of an annuity

## Description

Calculates the future value of an annuity (either an investment or loan) based on a regular number of payments of a fixed value and a static interest rate over the period of the annuity.

### IPmt Function

### Microsoft.VisualBasic.Financial

```
IPmt(rate, per, nper, pv[, fv[, due]])
```

*rate* required; Double

The interest rate per period.

*per* required; Double

The period for which a payment is to be computed.

*nper* required; Double

The total number of payment periods.

*pv* required; Double

The present value of a series of future payments.

*fv* optional; Double

The future value or cash balance after the final payment. If omitted, the default value is 0.

*due* optional; `DueDate` enumeration

A value indicating when payments are due. `DueDate.EndOfPeriod` (or 0) indicates that payments are due at the end of the payment period; `DueDate.BegOfPeriod` (or 1) indicates that payments are due at the beginning of the period. If omitted, the default value is `DueDate.EndOfPeriod`.

## Return Value

A Double representing the interest payment

## Description

Computes the interest payment for a given period of an annuity based on periodic, fixed payments and a fixed interest rate. An annuity is a series of fixed cash payments made over a period of time. It can be either a loan payment or an investment.

### IRR Function

### Microsoft.VisualBasic.Financial

```
IRR(valuearray()[, guess])
```

*valuearray*( ) required; array of Double

An array of cash flow values

*guess* optional; Double

Estimated value to be returned by the function

## Return Value

A Double representing the internal rate of return

## Description

Calculates the internal rate of return for a series of periodic cash flows (payments and receipts).

The internal rate of return is the interest rate generated by an investment consisting of payments and receipts that occur at regular intervals. It is generally compared to a "hurdle rate," or a minimum return, to determine whether a particular investment should be made.

### MIRR Function

### Microsoft.VisualBasic.Financial

`MIRR(valuearray( ), financerate, reinvestrate)`

`valuearray()` required; Array of Double

An array of cash flow values

`financerate` required; Double

The interest rate paid as the cost of financing

`reinvestrate` required; Double

The interest rate received on gains from cash investment

## Return Value

A Double representing the modified internal rate of return

## Description

Calculates the modified internal rate of return, which is the internal rate of return when payments and receipts are financed at different rates.

## NPer Function

## Microsoft.VisualBasic.Financial

`NPer(rate, pmt, pv [, fv [, due]])`

`rate` required; Double

The interest rate per period.

`pmt` required; Double

The payment to be made each period.

`pv` required; Double

The present value of the series of future payments or receipts.

`fv` optional; Double

The future value of the series of payments or receipts. If omitted, the default value is 0.

`due` optional; `DueDate` enumeration

A value indicating when payments are due. `DueDate.EndOfPeriod` (0) indicates that payments are due at the end of the payment period, and `DueDate.BegOfPeriod` (1) indicates that payments are due at the beginning of the period. If omitted, the default value is 0.

## Return Value

A Double indicating the number of payments

## Description

Determines the number of payment periods for an annuity based on fixed periodic payments and a fixed interest rate.

### NPV Function

Microsoft.VisualBasic.Financial

---

`NPV(rate, valuearray( ) )`

*rate* required; Double

The discount rate over the period, expressed as a decimal

*valuearray()* required; Double

An array of cash flow values

## Return Value

A Double specifying the net present value

## Description

Calculates the net present value of an investment based on a series of periodic variable cash flows (payments and receipts) and a discount rate.

The *net present value* is the value today of a series of future cash flows discounted at some rate back to the first day of the investment period.

### Pmt Function

Microsoft.VisualBasic.Financial

`Pmt(rate, nper, pv[, fv[, due]])`

*rate* required; Double

The interest rate per period.

*nper* required; Double

The total number of payment periods.

*pv* required; Double

The present value of the series of future payments.

*fv* optional; Double

The future value or cash balance after the final payment.

*due* optional; DueDate enumeration

A value indicating when payments are due. `EndOfPeriod` (0) indicates that payments are due at the end of the payment period; `BegOfPeriod` (1) indicates that payments are due at the beginning of the period. If omitted, the default value is 0.

## Return Value

A Double representing the monthly payment

## Description

Calculates the payment for an annuity based on periodic, fixed payments and a fixed interest rate. An annuity can be either a loan or an investment.

### PPmt Function

### Microsoft.VisualBasic.Financial

```
PPmt(rate, per, nper, pv[, fv[, due]])
```

*rate* required; Double

The interest rate per period.

*per* required; Double

The period for which a payment is to be computed.

*nper* required; Double

The total number of payment periods.

*pv* required; Double

The present value of a series of future payments.

*fv* optional; Object

The future value or cash balance after the final payment. If omitted, the default value is 0.

*due* optional; DueDate enumeration

A value indicating when payments are due. It can be either `DueDate.EndOfPeriod`, for payments due at the end of the period, or `DueDate.BegOfPeriod` for payments due at the beginning of the period.

The default value is `DueDate.EndOfPeriod`.

## Return Value

A `Double` representing the principal paid in a given payment

## Description

Computes the payment of principal for a given period of an annuity, based on periodic, fixed payments and a fixed interest rate. An annuity is a series of fixed cash payments made over a period of time. It can be either a loan payment or an investment.

## PV Function

## Microsoft.VisualBasic.Financial

---

```
PV(rate, nper, pmt[, fv [, due]])
```

*rate* required; `Double`

The interest rate per period

*nper* required; `Integer`

The number of payment periods in the annuity

*pmt* required; `Double`

The payment made in each period

*fv* optional; `Double`

The future value of the loan or annuity

*due* optional; `DueDate`

Either `DueDate.BegOfPeriod` or `DueDate.EndOfPeriod`

## Return Value

A `Double` specifying the present value of an annuity

## Description

Calculates the present value of an annuity (either an investment or loan) based on a regular number of future payments of a fixed value and a fixed interest rate. The *present value* is the current value of a future stream of equal cash flows discounted at some fixed interest rate.

**Rate Function****Microsoft.VisualBasic.Financial**

---

```
Rate(nper, pmt, pv[, fv[, due[, guess]])
```

*nper* required; Double

The total number of periods in the annuity.

*pmt* required; Double

The payment amount per period.

*pv* required; Double

The present value of the payments or future receipts.

*fv* optional; Double

The future value or cash balance after the final payment. If omitted, its value defaults to 0.

*due* optional; DueDate enumeration

A flag indicating whether payments are due at the beginning of the payment period (a value of `DueDate.BegOfPeriod`) or at the end of the payment period (a value of `DueDate.EndOfPeriod`, the default).

*guess* optional; Double

An estimate of the value to be returned by the function. If omitted, its value defaults to .1 (10%).

**Return Value**

A Double representing the interest rate per period

**Description**

Calculates the interest rate for an annuity (a loan or an investment) that consists of fixed payments over a known duration.

**SLN Function****Microsoft.VisualBasic.Financial**

```
SLN(cost, salvage, life)
```

*cost* required; Double

The initial cost of the asset

*salvage* required; Double

The value of the asset at the end of its useful life

*life* required; Double

The length of the useful life of the asset

## Return Value

A Double representing depreciation per period

## Description

Computes the straight-line depreciation of an asset for a single period

### SYD Function

Microsoft.VisualBasic.Financial

---

`SYD(cost, salvage, life, period )`

*cost* required; Double

The initial cost of the asset

*salvage* required; Double

The value of the asset at the end of its useful life

*life* required; Double

The length of the useful life of the asset

*period* required; Double

The period whose depreciation is to be calculated

## Return Value

A Double giving the sum-of-years depreciation of an asset for a given period

## Description

Computes the sum-of-years' digits depreciation of an asset for a specified period. The sum-of-years' digits method allocates a larger amount of the depreciation in the earlier years of the asset.

## 1.20 Information

### Erl Property

---

See [Erl Property](#) under [Section 1.17](#).

### IsArray Function

---

See [IsArray Function](#) entry under [Section 1.11](#).

### IsDate Function

Microsoft.VisualBasic.Information

*IsDate(expression)*

*expression* required; any

Expression containing a date or time

### Return Value

Boolean indicating whether the expression can be converted to a Date

### Description

Determines if an expression is of type Date or can be converted to type Date

Returns `True` if *expression* is of type Date or can be converted to type Date. Uninitialized date variables also return `True`.

### IsDBNull Function

Microsoft.VisualBasic.Information

*IsDBNull(expression)*

*expression* required; any expression

Any value retrieved from or to be written to a database

## Return Value

Boolean

## Description

Determines whether *expression* evaluates to `DBNull` (that is, is equal to `System.DbNull.Value`).

## IsError Function

---

See [IsError Function](#) under [Section 1.17](#).

## IsNothing Function

**Microsoft.VisualBasic.Information**

`IsNothing(expression)`

*expression* required; any

Any variable or expression to be tested for a null object reference

## Return Value

Boolean

## Description

Determines whether *expression* evaluates to `Nothing`. The line:

```
If IsNothing(obj) Then
```

is equivalent to:

```
If obj Is Nothing Then
```

## IsNumeric Function

**Microsoft.VisualBasic.Information**

`IsNumeric(expression)`

*expression* required; any expression

An expression to be converted to a number

## Return Value

Boolean

## Description

Determines whether *expression* can be evaluated as a number. If the expression passed to *IsNumeric* evaluates to a number, `True` is returned; otherwise, *IsNumeric* returns `False`.

## IsReference Function

Microsoft.VisualBasic.Information

---

`IsReference(expression)`

*expression* required; any

Any potential reference type

## Return Value

Boolean

## Description

Returns `True` if *expression* contains reference type data, as opposed to value type data.

## RGB Function

See [RGB Function](#) under [Section 1.14](#).

## Rem Statement

`Rem comment`

`' comment`

`comment optional`

A textual comment to place within the code

## Description

Use the `Rem` statement or an apostrophe ( `'` ) to place remarks within the code.

### **ScriptEngine Property**

**Microsoft.VisualBasic.Globals**

---

```
ScriptEngine
```

## Return Value

A String containing the value "VB"

## Description

Indicates the programming language currently in use.

### **ScriptEngineBuildVersion Property**

**Microsoft.VisualBasic.Globals**

```
ScriptEngineBuildVersion()
```

## Return Value

An Integer containing the build number

## Description

Returns the build number of the VB.NET language engine.

### **ScriptEngineMajorVersion Property**

**Microsoft.VisualBasic.Globals**

```
ScriptEngineMajorVersion
```

## Return Value

An Integer containing the major version number

## Description

Indicates the major version (1, 2, etc.) of the programming language currently in use.

**ScriptEngineMinorVersion Property****Microsoft.VisualBasic.Globals**

---

`ScriptEngineMinorVersion`**Return Value**

An Integer containing the minor version number

**Description**

Indicates the minor version (the number to the right of the decimal point) of the programming language currently in use.

**SystemTypeName Function****Microsoft.VisualBasic.Information**

---

`SystemTypeName ( vbname )``vbname` required; String

The name of a VB.NET data type

**Return Value**

A String indicating the name of a CTS data type

**Description**

Returns the fully qualified type name of the CTS data type that corresponds to a particular Visual Basic data type.

**TypeName Function****Microsoft.VisualBasic.Information**`TypeName ( varname )``varname` required; String literal

Name of a variable

**Return Value**

String

## Description

Returns a string giving data type information about *varname*. The possible return values are:

| String returned | Variable contents                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------|
| Boolean         | 8-bit <code>True</code> or <code>False</code> value type                                              |
| Byte            | 8-bit binary value type                                                                               |
| Char            | 16-bit character value type                                                                           |
| Date            | 64-bit date and time value type                                                                       |
| DBNull          | Reference type indicating missing or nonexistent data                                                 |
| Decimal         | 96-bit fixed point numeric value type                                                                 |
| Double          | 64-bit floating point numeric value type                                                              |
| Error           | <code>Error</code> object                                                                             |
| Integer         | 32-bit integer value type                                                                             |
| Long            | 64-bit integer value type                                                                             |
| Nothing         | Object variable with no object currently assigned to it, uninitialized string, or undimensioned array |
| Object          | Reference type pointing to an unspecialized object                                                    |
| Short           | 16-bit integer value type                                                                             |
| Single          | 32-bit floating point numeric value type                                                              |
| String          | Reference type pointing to a string of 16-bit characters                                              |
| <objectclass>   | Reference type pointing to a specialized object created from class <objectclass>                      |
| <structure>     | A variable created from a structure or user-defined type named <i>structure</i>                       |
| <typename>()    | Dimensioned array                                                                                     |

## VarType Function

## Microsoft.VisualBasic.Information

`VarType (varname)`

*varname* required; any

The name of a variable

## Return Value

A member of the `VariantType` enumeration indicating the variable type

## Description

Determines the data type of a variable.

## VbTypeName Function

Microsoft.VisualBasic.Information

---

`VbTypeName ( urtname )`

*urtname* required; String

The name of a CTS datatype

### Return Value

A String containing the name of a VB.NET datatype

### Description

Returns the name of the VB.NET datatype that corresponds to a particular CTS datatype.

## 1.21 Input/Output

### EOF Function

Microsoft.VisualBasic.FileSystem

---

`EOF(filenumber)`

*filenumber* required; Integer

Any valid file number

### Return Value

A Boolean indicating whether the end of the file has been reached

### Description

Returns a Boolean indicating whether the end of the file has been reached. Applies to files opened for binary, random, or sequential input.

### FileAttr Function

Microsoft.VisualBasic.FileSystem

`FileAttr(filenumber)`

*filenumber* required; Integer

Any valid file number

### Return Value

An `OpenMode` constant, as shown in the following table:

| Mode   | Value |
|--------|-------|
| Input  | 1     |
| Output | 2     |
| Random | 4     |
| Append | 8     |
| Binary | 32    |

### Description

Returns the file-access mode for a file opened using the `FileOpen` procedure

## FileClose Procedure

Microsoft.VisualBasic.FileSystem

---

```
FileClose([filenumber][, filenumber][, ...])
```

*filenumber* optional; Integer

The file number (or numbers) of file (or files) opened using the *FileOpen* procedure

### Description

Closes one or more files opened with the *FileOpen* procedure

## FileGet, FileGetObject Procedures

Microsoft.VisualBasic.FileSystem

---

```
FileGet(FileNumber, Value, RecordNumber)
```

```
FileGetObject(FileNumber, Value, RecordNumber)
```

*FileNumber* required; Integer

Any valid file number

*Value* required; any (object for FileGetObject)

Variable in which to place file contents

*RecordNumber* optional; Integer

The location at which reading begins

### Description

Copies data from a file on disk into a variable.

## FileLen Function

Microsoft.VisualBasic.FileSystem

```
FileLen(pathname)
```

*pathname* required; String

The filename, along with its path and drive name (optionally)

### Return Value

A Long containing the length of the specified file in bytes

## Description

Specifies the length of a file on disk.

### FileOpen Procedure

### Microsoft.VisualBasic.FileSystem

---

```
FileOpen(filenumber, filename, mode, access, share, _
 recordlength)
```

*filenumber* required; Integer

An available file number.

*filename* required; String

The name of the file to open, along with an optional path.

*mode* optional; OpenMode enum

The file-access mode. Options are: `OpenMode.Append`, `OpenMode.Binary`, `OpenMode.Input`, `OpenMode.Output`, or `OpenMode.Random` (the default value).

*access* optional; OpenAccess enum

Specifies the allowable operations by the current process. Options are: `OpenAccess.Default`, `OpenAccess.Read`, `OpenAccess.ReadWrite` (the default value), or `OpenAccess.Write`.

*share* optional; OpenShare enum

Specifies the allowable operations by other processes. Options are: `OpenShare.Shared` (the default value), `OpenShare.LockRead`, `OpenShare.LockWrite`, or `OpenShare.LockreadWrite`.

*recordlength* optional; Integer (at most, 32767)

The length of the record (for random access) or of the I/O buffer (for sequential access).

## Description

Opens a disk file for reading and/or writing.

### FilePut, FilePutObject Procedures

### Microsoft.VisualBasic.FileSystem

```
FilePut(filenumber, value, [recordnumber])
FilePutObject(filenumber, value, [recordnumber])
```

*filenumber* required; Integer

Any valid file number

*value* required; any (object for FilePutObject)

The name of the variable containing the data to be written to the file

*recordnumber* optional; Integer

Record number (for random access) or byte number (for binary access) at which to begin the write operation

## Description

Writes data from a program variable to a disk file.

### FileWidth Procedure

Microsoft.VisualBasic.FileSystem

---

`FileWidth(filenumber, recordwidth)`

*filenumber* required; Integer

Any valid file number

*recordwidth* required; Numeric

A number between 0 and 255

## Description

Specifies a virtual file width when working with files opened with the *FileOpen* function.

### FreeFile Function

Microsoft.VisualBasic.FileSystem

`FreeFile( )`

## Return Value

An integer representing the next available file number

## Description

Returns the next available file number for use in a *FileOpen* function.

### Input Procedure

Microsoft.VisualBasic.FileSystem

`Input (filename, value)`

*filename* required; Integer

Any valid file number

*value* required; any

Data to read from file

## Description

Reads delimited data from a file into variables. This statement is used to read files that were created using the *Write* procedure, in which case the items are comma delimited with quotation marks around strings.

## InputString Function

Microsoft.VisualBasic.FileSystem

---

`InputString (filename, charcount)`

*filename* required; Integer

Any valid file number

*charcount* required; Integer

Number of characters to read from file

## Return Value

A String containing *charcount* characters

## Description

Reads data from a file into a string variable.

## LineInput Function

Microsoft.VisualBasic.FileSystem

`LineInput (filename)`

*filename* required; Integer

Any valid file number

## Return Value

A String containing the line read from the file

## Description

Assigns a single line from a sequential file opened in Input mode to a string variable.

### Loc Function

Microsoft.VisualBasic.FileSystem

---

`Loc(filenumber)`

*filenumber* required; Integer

Any valid file number

## Return Value

A Long indicating the current position of the read/write pointer in a file

## Description

Determines the current position of the file read/write pointer.

### Lock Procedure

Microsoft.VisualBasic.FileSystem

`Lock(filenumber[, record])`

*Syntax 1.*

`Lock(filenumber[, fromrecord, torecord])`

*Syntax 2.*

*filenumber* required; Integer

Any valid file number

*record* optional; Long

The record or byte number at which to commence the lock

*fromrecord* optional; Long

The first record or byte number to lock

*torecord* optional; Long

The last record or byte number to lock

## Description

The *Lock* procedure prevents another process from accessing a record, section, or whole file until it is unlocked by the

*Unlock* function.

Use the *Lock* procedure in situations where multiple programs or more than one instance of your program may need read and write access to the same data file.

## LOF Function

Microsoft.VisualBasic.FileSystem

---

`LOF(filenumber)`

*filenumber* required; Integer

Any valid file number

## Return Value

Long Integer

## Description

Returns the size of an open file in bytes.

## Print, PrintLine Procedures

Microsoft.VisualBasic.FileSystem

`Print(filenumber, [outputlist( )])`

`PrintLine(filenumber, [outputlist( )])`

*filenumber* required; Integer

Any valid file number.

*outputlist* optional; Parameter Array

A comma-separated list of expressions to output to a file. *outputlist* can be either a scalar variable, a list of comma-delimited expressions, or a parameter array. Its comma-delimited expressions or parameter array can include the following:

`Spc (n)` optional

Insert *n* space characters before expression.

`Tab (n)` optional

Position the insertion point either at the next print zone (by omitting *n*) or at column number (*n*).

*expression* optional; any

The data expression to output.

## Description

Outputs formatted data to a disk file opened for Append or Output

### Reset Procedure

Microsoft.VisualBasic.FileSystem

---

```
Reset()
```

## Description

Closes all files that have been opened using the *FileOpen* procedure.

### Seek Function

Microsoft.VisualBasic.FileSystem

---

```
Seek(filenumber)
```

*filenumber* required; Integer

Any valid file number

### Return Value

A Long indicating the current read/write position

## Description

Returns the current position of the read/write marker in the open file *filenumber*.

### Seek Procedure

Microsoft.VisualBasic.FileSystem

```
Seek(filenumber, position)
```

*filenumber* required; Integer

Any valid file number

*position* required; Long

Any whole number between 1 and 2,147,483,647

## Description

Places the read/write marker at a given position where the next read/write operation should occur.

## **Spc Function**

**Microsoft.VisualBasic.FileSystem**

---

`Spc ( n )`

*n* required; Integer

The number of spaces required

## **Return Value**

A String containing *n* spaces

## **Description**

Inserts spaces between expressions in a *Print* or *PrintLine* procedure.

## **Tab Function**

**Microsoft.VisualBasic.FileSystem**

`Tab[ ( column ) ]`

*column* optional; Short

A column number to which the insertion point will move before displaying or printing the next expression

## **Return Value**

A TabInfo structure

## **Description**

Moves the text-insertion point to a given column or to the start of the next print zone.

## 1.22 IDE

### #Region...#End Region Directive

---

```
#Region "identifier_string"
' code goes here
#End Region
identifier_string required; String literal
```

The title of the code block (or region)

### Description

Marks a block of code as an expandable and collapsible region or code block in the Visual Studio .NET editor.

## 1.23 Interaction

### AppActivate Procedure

Microsoft.VisualBasic.Interaction

---

[Interaction.]AppActivate(*title*)

*title* required; String or Integer

The name of the application as currently shown in the application window title bar. This can also be the task ID returned from the *Shell* function.

#### Description

Activates a window based on its caption.

### Beep Procedure

Microsoft.VisualBasic.Interaction

Beep

#### Description

Sounds a tone through the computer's speaker.

### Choose Function

Microsoft.VisualBasic.Interaction

Choose(*index*, *item\_1*[, *item\_2*, ...[, *item\_n*]])

*index* required; Single

An expression that evaluates to the (1-based) index of the object to choose from the list

*item\_1*-*item\_n* required; any

A comma-delimited list of values from which to choose, or a ParamArray containing values from which to choose

#### Named Arguments

No

#### Return Value

The object chosen from the list

## Description

Programmatically selects an object from a predefined list of objects (which are passed as parameters to the function) based on its ordinal position in the list. Using *Choose* is a simpler alternative to populating an array with fixed values.

### Command Function

### Microsoft.VisualBasic.Interaction

`Command( )`

## Return Value

A String containing the command-line arguments

## Description

Returns the command line arguments used when launching VB or an application created with VB.

### Environ Function

### Microsoft.VisualBasic.Interaction

`Environ(expression)`

*expression* required; String, or a numeric expression

If *expression* is a string, it must be the name of the required environment variable; if *expression* is numeric, it must be the 1-based ordinal number of the environment variable within the environment table.

## Return Value

A String containing the text assigned to *expression*

## Description

Returns the value assigned to an operating-system environment variable.

### IIf Function

### Microsoft.VisualBasic.Interaction

`IIf(expression, truepart, falsepart)`

*expression* required; Boolean

Expression to be evaluated

*truepart* required; any value or expression

Expression or value to return if *expression* is True

*falsepart* required; any value or expression

Expression or value to return if *expression* is False

## Return Value

The value or result of the expression indicated by *truepart* or *falsepart*

## Description

Returns one of two results, depending on whether *expression* evaluates to True or False. The function is typically avoided, particularly inside of a loop, because of its poor performance.

## InputBox Function

## Microsoft.VisualBasic.Interaction

```
InputBox(prompt[, title] [, defaultresponse] [, xpos] _
 [, ypos])
```

*prompt* required; String

The message in the dialog box

*title* optional; String

The title bar of the dialog box

*defaultresponse* optional; String

String to be displayed in the text box on loading

*xpos* optional; Numeric

The distance in twips from the left-hand side of the screen to the left-hand side of the dialog box

*ypos* optional; Numeric

The distance in twips from the top of the screen to the top of the dialog box

## Return Value

A String containing the contents of the text box from the *InputBox* dialog box

## Description

Displays a dialog box containing a prompt for the user, a text box for entering data, and an OK, a Cancel, and (optionally) a Help button. When the user clicks OK, the function returns the contents of the text box.

### MsgBox Function

### Microsoft.VisualBasic.Interaction

---

```
MsgBox(prompt[, buttons][, title])
```

*prompt* required; String

The text of the message to display in the message box dialog box

*buttons* optional; MsgBoxStyle enumeration

The sum of the `Button`, `Icon`, `Default Button`, and `Modality` constant values

*title* optional; String

The title displayed in the title bar of the message box dialog box

## Return Value

A `MsgBoxResult` enumeration constant indicating the button clicked by the user to close the message box

## Description

Displays a dialog box containing a message, buttons, and optional icon to the user. The action taken by the user is returned by the function in the form of an enumerated constant.

### Partition Function

### Microsoft.VisualBasic.Interaction

```
Partition(number, start, stop, interval)
```

*number* required; Long

Number to evaluate against the intervals

*start* required; Long

Start of the range. Must be non-negative

*stop* required; Long

End of the range. Must be greater than *start*

*interval* required; Long

Size of each interval into which the range is partitioned

## Return Value

A String containing the range within which *number* falls

## Description

Returns a string that describes which interval contains the number.

### Shell Function

### Microsoft.VisualBasic.Interaction

```
Shell(pathname[,style][,Wait][,Timeout])
```

*pathname* required; String

Name of the program to execute

*style* optional; AppWinStyle enumeration

The style of window and whether it receives the focus; its default value is `AppWinStyle.MinimizedFocus`.

*Wait* optional; Boolean

Boolean indicating whether to wait for the *pathname* application to finish execution before continuing execution of subsequent code; its default value is `False`.

*Timeout* optional; Integer

If *Wait* is `True`, number of milliseconds to wait for the *pathname* application to terminate before the *Shell* function times out. Its default value is -1 indicating that there is no timeout value.

## Return Value

An Integer representing the Process ID, or 0

## Description

Launches another application and, if successful, returns that application's task ID.

### Switch Function

### Microsoft.VisualBasic.Interaction

```
Switch(expr-1, value-1[, expr-2, value-2 ... [, _
 expr-n, value-n]])
```

*expr* required; Object

A number of expressions to be evaluated

*value* required; Object

An expression or value to return if the associated expression evaluates to `True`

## Return Value

An Object value or expression

## Description

Evaluates a list of expressions and, on finding the first expression to evaluate to `True`, returns an associated value or expression.

If none of the expressions is `True`, the *Switch* function returns `Nothing`.

If multiple expressions are `True`, *Switch* returns the value that corresponds to the first `True` expression.

## 1.24 Mathematics

### Abs Function

System.Math

---

`Math.Abs(value)`

*value* required; any valid numeric expression

A number whose absolute value is to be returned

### Return Value

The absolute value of *value*. The data type is the same as that of the argument passed to the function

### Description

Returns the absolute value of *value*. If *value* is an uninitialized variable, the return value is 0.

### Acos Function

System.Math

`Math.Acos(d)`

*d* required; Double or any valid numeric expression

A cosine, which is a number greater than or equal to -1 and less than or equal to 1

### Return Value

A Double between 0 and pi that is the arccosine of *d* in radians

### Description

Returns the arccosine of *d* in radians.

### Asin Function

System.Math

`Math.Asin(d)`

*d* required; Double or any valid numeric expression

A number representing a sine, which can range from -1 to 1

## Return Value

A Double between  $-\pi/2$  and  $\pi/2$  that is the arcsine of  $d$  in radians

## Description

Returns the arcsine of  $d$ , in radians

### Atan Function

System.Math

---

`Math.Atan( $d$ )`

$d$  required; Double or any valid numeric expression

A number representing a tangent

## Return Value

A Double that is the arctangent in radians of  $d$ , in the range  $-\pi/2$  to  $\pi/2$

## Description

Takes the ratio of two sides of a right triangle ( $d$ ) and returns the corresponding angle in radians. The ratio is the length of the side opposite the angle divided by the length of the side adjacent to the angle.

### Atan2 Function

System.Math

`Math.Atan2( $y$ ,  $x$ )`

$x$  required; Double

The x coordinate of a point

$y$  required; Double

The y coordinate of a point

## Return Value

A Double that is the arctangent of the *ratio*  $x/y$ , in radians

## Description

Returns the angle in the Cartesian plane formed by the x-axis and a vector starting from the origin (0,0) and

terminating at the point  $(x, y)$ . More specifically, the return value  $q$  satisfies the following:

- For  $(x, y)$  in quadrant 1,  $0 < q < \pi/2$
- For  $(x, y)$  in quadrant 2,  $\pi/2 < q < \pi$
- For  $(x, y)$  in quadrant 3,  $-\pi < q < -\pi/2$
- For  $(x, y)$  in quadrant 4,  $-\pi/2 < q < 0$

## Ceiling Function

System.Math

---

`Math.Ceiling(a)`

*a* required; Double

Any valid numeric expression

### Return Value

A Double containing the smallest integer greater than or equal to the argument *a*

### Description

Returns the smallest integer greater than or equal to the argument *a*.

## Cos Function

System.Math

`Math.Cos(d)`

*d* required; Double or numeric expression

An angle in radians

### Return Value

A Double data type denoting the cosine of an angle

### Description

Takes an angle specified in radians and returns a ratio representing the length of the side adjacent to the angle divided by the length of the hypotenuse.

## Cosh Function

System.Math

`Math.Cosh(value)`

*value* required; Double or numeric expression

An angle in radians

## Return Value

A Double denoting the hyperbolic cosine of the angle

## Description

Returns the hyperbolic cosine of an angle.

## E Field

**System.Math**

---

`Math.E`

## Description

This field returns the approximate value of the irrational number  $e$ , which is the base of the natural logarithm and the base of the natural exponential function. In particular:

`Math.E = 2.71828182845905`

## Exp Function

**System.Math**

`Math.Exp(d)`

*d* required; Numeric

Any valid numeric expression

## Return Value

Double

## Description

Returns a Double representing the natural number  $e$  raised to the power  $d$ . Note that the irrational number  $e$  is *approximately* 2.7182818.

## Fix Function

See [Fix Function](#) entry under [Section 1.14](#).

## Floor Function

System.Math

---

```
Math.Floor(d)
d required; Double
```

### Return Value

A Double containing the largest integer less than or equal to the argument  $d$ .

### Description

Returns the largest integer less than or equal to the argument  $d$ .

## IEEERemainder Function

System.Math

```
Math.IEERemainder(x, y)
x and y required; Double
```

### Return Value

Returns the remainder after dividing  $x$  by  $y$ .

### Description

Returns a Double whose value is the remainder after dividing  $x$  by  $y$ .

## Int Function

See [Int Function](#) entry under [Section 1.14](#).

## Log Function

System.Math

`Math.Log(d)`

Syntax 1.

`Math.Log(a, newbase)`

Syntax 2.

*d* or *a* required; Double

A numeric expression greater than zero

*newbase* required; Double

The base of the logarithm

## Return Value

Double

## Description

Returns the natural (base e) logarithm of a given number (the first syntax) or the logarithm of a given number in a specified base (the second syntax).

## Log10 Function

**System.Math**

`Math.Log10(d)`

*d* required; Double

A numeric expression greater than zero

## Return Value

Double

## Description

Returns the common (base-10) logarithm of a given number.

## Max Function

**System.Math**

`Math.Max(val1, val2)`

*val1, val2* required; any

A numeric data type or expression

## Return Value

Returns the maximum of *val1* and *val2*, in the wider datatype of the two numbers

## Description

Returns the maximum of *val1* and *val2*.

### Min Function

System.Math

```
Math.Min(val1, val2)
```

*val1*, *val2* required; any numeric

A numeric data type or expression

## Return Value

Returns the minimum of *val1* and *val2* in the wider data type of the two numbers

## Description

Returns the minimum of two numbers.

### Mod Operator

```
result = number1 Mod number2
```

*number1*, *number2* required; any

A numeric expression

## Return Value

Returns the modulus

## Description

Returns the modulus, that is, the remainder when *number1* is divided by *number2*. This return value is a non-negative integral data type.

### Partition Statement

See [Partition Function](#) entry under [Section 1.23](#).

## Pi Field

System.Math

---

Math.PI

## Return Value

A Double containing the approximate value of the irrational number  $\pi$

## Description

This field returns the approximate value of the irrational number  $\pi$ . In particular:

Math.PI = 3.14159265358979

## Pow Function

System.Math

```
result = Math.Pow(x, y)
x, y required; Double
```

## Return Value

A Double that is  $x$  (the base) raised to the power  $y$  (the exponent)

## Description

This is a generalized exponential function; it returns the result of a number raised to a specified power.

## Randomize Procedure

Microsoft.VisualBasic.VBMath

```
Randomize([number])
number optional; Object or any valid numeric expression
```

A number used to initialize the random-number generator

## Description

Initializes the random-number generator.

## Rnd Function

Microsoft.VisualBasic.VBMath

---

`Rnd[ ( number ) ]`

*number* optional; Single

Any valid numeric expression that serves as a seed value

## Return Value

A Single data type random number

## Description

Returns a random number.

## Round Function

System.Math

`Math.Round( value [ , digits ] )`

*value* required; Numeric expression

Any numeric expression

*digits* optional; Integer

The number of places to include after the decimal point

## Return Value

The same data type as *value*

## Description

Rounds a given number to a specified number of decimal places.

## Sign Function

System.Math

`Sign(value)`

*value* required; any numeric type, including Decimal

A numeric expression

## Return Value

Integer

## Description

Determines the sign of a number.

## Sin Function

System.Math

---

`Sin(a)`

*a* required; Numeric

An angle expressed in radians

## Return Value

A Double containing the sine of an angle

## Description

Returns the ratio of two sides of a right triangle in the range -1 to 1.

## Sinh Function

System.Math

`Math.Sinh(value)`

*value* required; Double or numeric expression

An angle in radians

## Return Value

A Double denoting the hyperbolic sine of the angle

## Description

Returns the hyperbolic sine of an angle.

## Sqrt Function

System.Math

`Sqr(d)`

*d* required; Double

Any numeric expression greater than or equal to 0

## Return Value

A Double containing the square root of *d*

## Description

Calculates the square root of a given number.

## Tan Function

System.Math

---

`Tan(a)`

*a* required; Double

An angle in radians

## Return Value

A Double containing the tangent of an angle

## Description

Returns the ratio of two sides of a right angle triangle.

## Tanh Function

System.Math

`Math.Tanh(number)`

*number* required; Double or numeric expression

An angle in radians

## Return Value

A Double denoting the hyperbolic tangent of the angle

## Description

Returns the hyperbolic tangent of an angle.

## 1.25 Program Structure and Flow

### Call Statement

---

[Call] *procedurename*[(*argumentlist*)]

*procedurename* required; n/a

The name of the subroutine being called

*argumentlist* optional; any

A comma-delimited list of arguments to pass to the subroutine being called

### Description

Passes execution control to a procedure, function, or DLL procedure or function.

#### CallByName Function

#### Microsoft.VisualBasic.Interaction

CallByName(*Object*, *ProcName*, *UseCallType*, *Args*( ))

*Object* required; Object

A reference to the object containing the procedure being called.

*ProcName* required; String

The name of the procedure to call.

*UseCallType* required; CallType constant

A constant of type `CallType` indicating what type of procedure is being called. The `CallType` constants are:

| Constant | Value | Description                                       |
|----------|-------|---------------------------------------------------|
| Method   | 1     | The called procedure is a method                  |
| Get      | 2     | The called procedure retrieves a property value   |
| Let      | 4     | The called procedure sets the value of a property |

*Args* optional; any

A ParamArray argument representing the arguments required by the procedure being called.

### Named Arguments

Yes, if *Args*( ) is omitted

## Return Value

Depends on the return value (if any) of the called procedure

## Description

Provides a method for calling a class member by name.

Since *ProcName* is a string expression, rather than the literal name of a routine, it is possible to call routines dynamically at runtime using a string variable to hold the various procedure names.

## Do...Loop Statement

---

```
Do [{While | Until} condition] Syntax 1.
 [statements]
```

```
[Exit Do]
 [statements]
```

```
Loop
```

```
Do Syntax 2.
```

```
 [statements]
```

```
[Exit Do]
```

```
 [statements]
```

```
Loop [{While | Until} condition]
```

*condition* optional; Boolean expression

An expression that evaluates to `True` or `False`

*statements* optional

Program statements that are repeatedly executed while, or until, *condition* is `True`

## Description

Repeatedly executes a block of code while or until a condition becomes `True`.

## End... Statement

```
End
End Class
End Enum
End Function
End Get
End If
End Interface
End Module
End Namespace
End Property
End Select
End Set
End Structure
End Sub
End SyncLock
End Try
End With
End While
```

## Description

Ends a procedure or a block of code.

## Exit . . . Statement

```
Exit Do
Exit For
Exit Function
Exit Property
Exit Select
Exit Sub
Exit Try
Exit While
```

## Description

Prematurely exits a block of code.

## For . . . Next Statement

```

For counter = initial_value To maximum_value _
 [Step stepcounter]
 'code to execute on each iteration
[Exit For]
Next [counter]

```

*counter* required (optional with Next statement); any valid numeric variable

A variable that serves as the loop counter

*initial\_value* required; any valid numeric expression

The starting value of *counter* for the first iteration of the loop

*maximum\_value* required; any valid numeric expression

The value of *counter* during the last iteration of the loop

*stepcounter* optional (required if Step is used); any valid numeric expression

The amount by which *counter* is to be incremented or decremented on each iteration of the loop

## Description

Defines a loop that executes a given number of times, as determined by a loop counter.

To use the `For . . . Next` loop, you must assign a numeric value to a counter variable. This counter is either incremented or decremented automatically with each iteration of the loop. In the `For` statement, you specify the value that is to be assigned to the counter initially and the maximum value the counter will reach for the block of code to be executed. The `Next` statement marks the end of the block of code that is to execute repeatedly, and it also serves as a kind of flag that indicates that the counter variable is to be modified.

## For Each...Next Statement

```

For Each element In group
 [statements]
[Exit For]
[statements]
Next [element]

```

*element* required; Object or any user-defined object type

An object variable to which the current element from the group is assigned

*group* required

An object collection or array

*statements* optional

A line or lines of program code to execute within the loop

## Description

Loops through the items of a collection or the elements of an array.

## GoTo Statement

---

GoTo *label*

*label* required; string literal

A subroutine name

## Description

Passes execution to a specified line within a procedure.

## If...Then...Else Statement

*Standard syntax:*

```
If condition Then
 [statements]
[ElseIf condition-n Then
 [elseifstatements] ...
[Else
 [elasticsearches]]
End If
```

*One-line syntax:*

```
If condition Then [statements] [Else elasticsearches]
```

*condition* required; Boolean

An expression returning either `True` or `False` or an object type

*statements* optional

Program code to be executed if *condition* is true

*condition-n* optional

Same as condition

*elseifstatements* optional

Program code to be executed if the corresponding *condition-n* is True

*elstatements* optional

Program code to be executed if the corresponding *condition* or *condition-n* is False

## Description

Executes a statement or block of statements based on the Boolean (True or False) value of an expression.

## Return Statement

---

Return *In a subroutine*

Return *ReturnValue* *In a function*

*ReturnValue* required; any

The return value of the function

## Description

Returns to the calling program from a subroutine or function.

## Select Case Statement

Select Case *testexpression*

[Case *expressionlist-n*

[*statements-n*] ...

[Case Else

[*elstatements*]]

End Select

*testexpression* required; any

Any numeric or string expression whose value determines which block of code is executed.

*expressionlist-n* required; any

Comma-delimited list of expressions to compare values with *testexpression*

*statements-n* optional

Program statements to execute if a match is found between any section of *expressionlist* and *testexpression*

*elsestatements* optional

Program statements to execute if a match between *testexpression* and any *expressionlist* cannot be found

*expressionlist* can use any (or a combination of any) of the following:

| expressionlist syntax                   | Examples                                   |
|-----------------------------------------|--------------------------------------------|
| <i>expression</i>                       | iVar - iAnotherVar<br>iVar                 |
| <i>expression To expression</i>         | 5 To 10<br>8 To 11, 13 to 15<br>"A" To "D" |
| <i>Is comparisonoperator expression</i> | Is = 10                                    |

## Description

Allows for conditional execution of a block of code, typically out of three or more code blocks, based on some condition. Use the *Select Case* statement as an alternative to complex nested *If...Then...Else* statements.

## Stop Statement

Stop

## Description

Suspends program execution.

## While...End While Statement

```
While condition
 [statements]
[Exit While]
 [statements]
End While
```

*condition* required; Numeric or String

An expression evaluating to True or False

*statements* optional

Program statements to execute while condition remains `True`

`Exit While` optional; Keyword

Exits the While loop

## Description

Repeatedly executes program code while a given condition remains `True`.

## 1.26 Programming

### AddHandler Statement

---

*AddHandler NameOfEventSender, AddressOf NameOfEventHandler*  
*NameOfEventSender* required; String literal

The name of a class or object instance and its event, such as `Button1.Click`

*NameOfEventHandler* required; String literal

The name of a subroutine that is to serve as the event handler for *NameOfEventSender*

### Description

Binds an event handler to a built-in or custom event. This makes it possible to bind several event handlers to a single event.

- *NameOfEventSender* takes the form `class.event` or `object.event`
- You can stop handling events defined by the `AddHandler` statement by calling the `RemoveHandler` statement

### AddressOf Operator

*AddressOf procedurename*  
*procedurename* required

The name of a procedure that is referenced by the procedure delegate

### Description

The `AddressOf` operator returns a procedure delegate instance that references a specific procedure. It is used in the following situations:

- If a parameter to a procedure (a VB procedure or a Win32 API function) requires a function pointer (the address of a function), then we can pass the expression:

`AddressOf functionname`

where *functionname* is the name of the function. This function is called a *callback function*.

- `AddressOf` is also used to create delegate objects, as in:

```
delg = New ADelegate(AddressOf obj.AMethod)
```

- `AddressOf` is used to bind event handlers to events through the `AddHandler` statement:

```
AddHandler Form1.Click, AddressOf Me.Form1Click
```

## Class...End Class Statement

---

See [Class...End Class Statement](#) entry under [Section 1.16](#).

## COMClass Attribute

## Microsoft.VisualBasic.COMClassAttribute

---

### Description

Adds metadata that allows a .NET class to be exposed as a COM object. You can supply the attribute with a class identifier, an interface identifier, and an event identifier. All are globally unique identifiers (GUIDs) that can be generated either by using the *guidgen.exe* utility or automatically by using the COM Class Wizard. They ensure that the COM component retains the same GUIDs when it is recompiled.

### Constructor

```
New([[classID], interfaceID], eventID)
classID String
```

The class identifier (CLSID) that will uniquely identify the COM class

```
interfaceID String
```

The interface identifier (IID) that uniquely identifies the class' default COM interface

```
eventID String
```

The event identifier that uniquely identifies an event

### Properties

```
ClassID String
```

Read-only. Provides the CLSID that uniquely identifies a COM class. Its value is set by the *classID*

parameter of the class constructor.

#### *EventID String*

Read-only. Provides the GUID that uniquely identifies an event. Its value is set by the *eventID* parameter of the class constructor.

#### *InterfaceID String*

Read-only. Provides the IID that uniquely identifies a COM interface. Its value is set by the *interfaceID* parameter of the class constructor.

#### *InterfaceShadows Boolean*

Indicates whether the COM interface name is the same as the name of another member of the class or the base class. Its default value is `False`.

## **CreateObject Function**

## **Microsoft.VisualBasic.Interaction**

```
objectvariable = CreateObject(progid [, servername])
```

*objectvariable* required; Object

A variable to hold the reference to the instantiated object

*progid* required; String

The programmatic identifier (or ProgID) of the class of the object to create

*servername* optional; String

The name of the server on which the object resides

## **Named Arguments**

No

## **Return Value**

A reference to a COM or ActiveX object

## **Description**

Creates an instance of an OLE Automation (ActiveX) object.

Prior to calling the methods, functions, or properties of a COM or ActiveX object, you are required to create an instance of that object. Once an object is created, reference it in code using the object variable you defined.

## Declare Statement

---

See [Declare Statement](#) entry under [Section 1.16](#).

## Event Statement

---

```
[accessmodifier] [Shadows] Event eventName [(arglist)]
 [Implements interfacename.interfaceeventname]
```

*accessmodifier* optional; Keyword

Can be one of `Public`, `Private`, `Protected`, `Friend`, and `Protected Friend`.

*Shadows* optional; Keyword

Indicates that the event shadows any programming elements of the same name in a base class.

*eventName* required; String literal

The name of the event.

*arglist*

is optional and has the following syntax:

```
[ByVal | ByRef] varname[()] [As type]
```

`ByVal` optional; Keyword

The argument is passed by value; that is, a local copy of the variable is assigned the value of the argument. `ByVal` is the default method of passing variables.

`ByRef` optional; Keyword

The argument is passed by reference; that is, the local variable is simply a reference to the argument being passed. All changes made to the local variable are reflected in the calling argument.

*varname* required; String literal

The name of the local variable containing either the reference or value of the argument.

*type* optional; Keyword

The data type of the argument. It can be `Byte`, `Boolean`, `Char`, `Short`, `Integer`, `Long`, `Single`, `Double`, `Decimal`, `Date`, `String`, `Object`, or any user-defined structure, object type, or data type defined in the BCL.

Implements *interfacename.interfaceeventname* optional

Indicates that the event implements a particular event named *interfaceeventname* in the interface named *interfacename*.

## Description

Defines a custom event that the object can raise at any time using the `RaiseEvent` statement.

## Environ Function

---

See [Environ Function](#) entry under [Section 1.23](#).

## Get Statement

```
Get ()
 [statements]
End Get
statements optional
```

Program code to be executed when the Property Get procedure is called

## Description

Defines a Property Get procedure that returns a property value to the caller.

## GetObject Function

## Microsoft. VisualBasic.Interaction

```
GetObject([pathname] [, class])
pathname optional; String
```

The full path and name of the file containing the COM (or ActiveX) object.

*class* optional; String

The class of the object. The *class* argument has these parts:

*Appname* required; String

The name of the application.

*Objecttype* required; String

The class of object to create, delimited from *Appname* by using a period ( . ). For example, *Appname.Objecttype*.

## Return Value

A reference to an ActiveX object

## Description

Accesses an ActiveX server held within a specified file.

## Handles Keyword

---

Handles *name.event*

*name* required; String literal

The name of the class or object whose event the subroutine is handling

*event* required; String literal

The name of the event that the subroutine is handling

## Description

Defines a procedure as the event handler for a particular event.

## Implements Keyword

Implements *interfacename.interfacemember* [, ...]

*interfacename* required; String literal

The name of the interface being implemented by a class

*interfacemember* required; String literal

The name of the interface property, function, procedure, or event that is being implemented by a class

## Description

Indicates that a class member provides the implementation of a member defined in an interface.

## Implements Statement

---

```
Implements InterfaceName [,InterfaceName] [, ...]
```

*InterfaceName* required; String literal

The name of the interface that a class implements

## Description

The `Implements` statement specifies that you will *implement* an interface within the class in which the `Implements` statement appears.

## Imports Statement

---

```
Imports [aliasname =] namespace [.element]
```

*aliasname* optional; String literal

The name by which the namespace will be referenced in the module

*namespace* required; String literal

The name of the namespace being imported

*element* optional

The name of an element in the namespace

## Description

Imports namespaces or parts of namespaces, making their members available to the current module.

## Inherits Statement

```
Inherits classname
```

*classname* required; String literal

The name of the inherited (base) class

## Description

Specifies the name of the class that is being inherited, that is, the base class. The statement can appear immediately after the `Class` statement or the `Interface` statement.

## Interface Statement

---

```
[accessmodifier] [Shadows] Interface name
...statements
End Interface
```

*accessmodifier* optional; Keyword

One of the following keywords, which determines the visibility of the interface:

`Public` optional; Keyword

Indicates that the interface is publicly accessible anywhere both inside and outside of the project.

`Private` optional; Keyword

Indicates that the interface is accessible to any nested types, as well as to the type (if any) in which it is defined.

`Protected` optional; Keyword

Indicates that the interface is accessible only to derived classes; a protected interface can only be declared inside of a class.

`Friend` optional; Keyword

Indicates that the interface is accessible only within the project that contains the interface definition.

`Protected Friend` optional; Keyword

Indicates that the interface is declared inside of a class and that it is accessible throughout the project that contains the interface definition, as well as to derived classes.

`Shadows` optional; Keyword

Indicates that the interface shadows an identically named element in a base class.

*name* required; String literal

The name of the interface.

*statements* required

Code that defines the interface members that derived classes must implement.

## Description

Defines a virtual base class along with its public members. The interface can then be implemented by derived classes using the `Implements` statement.

## Is Operator

---

```
object1 Is object2
object1 required; Object or any reference type
object2 required; Object or any reference type
```

## Return Value

Boolean

## Description

Compares two object variables or reference variables to determine whether they reference the same object.

## Len Function

## Microsoft.VisualBasic.Strings

```
Len(expression)
expression required; any
```

Any valid variable name or expression

## Return Value

Integer

## Description

Counts the number of characters within a string or the size of a given variable.

## Me Operator

Me

## Description

Represents a reference to the current class from within the class.

## MyBase Keyword

---

`MyBase`

### Description

Provides a reference to the base class from within a derived class. If you want to call a member of the base class from within a derived class, you can use the syntax:

`MyBase.MemberName`

where *MemberName* is the name of the member. This will resolve any ambiguity if the derived class also has a member of the same name.

## MyClass Keyword

`MyClass`

### Description

Provides a reference to the class in which the keyword is used.

## Namespace Statement

```
Namespace name
 component types
End Namespace
name required; String literal
```

The name of the namespace

*component types* required

The elements that are being declared as part of the namespace, including Enums, Structures, Interfaces, Classes, Delegates, Modules, and other namespaces

### Description

Declares a namespace and specifies the items in it.

## Property Statement

---

See [Property Statement](#) entry under [Section 1.16](#).

## RaiseEvent Statement

---

```
RaiseEvent eventName([arglist])
eventName required; String literal
```

The name of the event

*arglist* optional; any (defined by the Event statement)

A comma-delimited list of arguments

### Description

Generates a predefined, custom event within any procedure of an object module

## RemoveHandler Statement

```
RemoveHandler NameOfEventSender, AddressOf NameOfEventHandler
NameOfEventSender required; String literal
```

The name of a class or object instance and its event, such as Button1.Click

*NameOfEventHandler* required; String literal

The name of a subroutine to remove as event handler for *NameOfEventSender*

### Description

Removes a previous binding of an event handler to a built-in or custom event.

## Shadows Keyword

---

Shadows

## Description

When a member of a derived class has the same name as a member of the same type in the base class, and the keywords `Overridable` and `Overrides` are used appropriately, then the derived class member overrides the base class member. That is, any reference to the member using a derived class object refers to the implementation in the derived class.

Shadowing works in a similar way but allows any member type to "override" any other member type. Thus, for example, a method can "override" a property.

## SyncLock Statement

---

```
SyncLock expression
...[code]
End SyncLock
```

*expression* required; any reference type (class, module, interface, array, or delegate)

An expression yielding a single result that can be used to determine the accessibility of *code*

*code* optional

The code statements to which access is synchronized and that will be executed sequentially

## Description

Prevents multiple threads of execution in the same process from accessing shared data or resources at the same time

## WithEvents Keyword

```
Dim|Private|Public WithEvents objVarName As objectType
objVarName required; String
```

The name of any object variable that refers to an object that exposes events

*objectType* required; any object type other than the generic `Object`

The ProgID of a referenced object

## Description

Informs VB that the object being referenced exposes events for which you intend to provide event handlers.

## 1.27 Registry

### DeleteSetting Procedure

Microsoft.VisualBasic.Interaction

---

```
DeleteSetting(appname[, section[, key]])
```

*appname* required; String

The name of the application. This must be a subkey of the HKEY\_CURRENT\_USER\Software\VB and VBA Program Settings registry key.

*section* optional; String

The name of the application key's subkey that is to be deleted. *section* can be a single key or a registry path separated with backslashes.

*key* optional; String

The name of the value entry to delete.

### Description

Deletes a complete application key, one of its subkeys, or a single value entry from the Windows registry.

### GetAllSettings Function

Microsoft.VisualBasic.Interaction

```
GetAllSettings(appname, section)
```

*appname* required; String

Name of the application

*section* required; String

Relative path from *appname* to the key containing the settings to retrieve

### Return Value

An object containing a two-dimensional array of strings

### Description

Returns the registry value entries and their corresponding values for the application.

## GetSetting Function

Microsoft.VisualBasic.Interaction

---

```
GetSetting(appname, section, key[, default])
```

*appname* required; String

The name of the application

*section* required; String

The path from the application key to the key containing the value entries

*key* required; String

The name of the value entry whose value is to be returned

*default* optional; String

The value to return if no value can be found

## Return Value

A string containing the value of the specified *key*; *default* if *key*, *section*, or *appname* were not found.

## Description

Returns a single value from a specified section of your application's entry in the HKEY\_CURRENT\_USER\Software\VB and VBA Program Settings\ branch of the registry.

## SaveSetting Procedure

Microsoft.VisualBasic.Interaction

```
SaveSetting(appname, section, key, setting)
```

*appname* required; String

The name of the application

*section* required; String

The name of the registry key

*key* required; String

The name of the value entry whose value is to be saved

*setting* required; String or numeric

The value to save

## Description

Creates or saves an entry for a VB application in the Windows registry.

## 1.28 String Manipulation

### Asc, AscW Functions

Microsoft.VisualBasic.Strings

---

*Asc*(*string*)

*AscW*(*str*)

*string*, *str* required; String or Char

Any expression that evaluates to a *nonempty* string

### Return Value

An Integer that represents the character code of the first character of the string; the range for the returned value is 0 - 255 on nonDBCS systems, and -32768 to 32767 on DBCS systems

### Description

Returns an Integer representing the character code for the first character of the string passed to it. All other characters in the string are ignored.

### Chr, ChrW Functions

Microsoft.VisualBasic.Strings

*Chr*(*charcode*)

*ChrW*(*charcode*)

*charcode* required; Integer

An expression that evaluates to a Unicode character code

### Return Value

A Char that contains the character represented by *charcode*

### Description

Returns the character represented by the *charcode*.

### Filter Function

Microsoft.VisualBasic.Strings

```
Filter(Source, Match[, Include[, Compare]])
```

*Source* required; String or Object

An array containing values to be filtered.

*Match* required; String

The substring of characters to find in the elements of the source array.

*Include* optional; Boolean

A Boolean (`True` or `False`) value. If `True` (the default value), *Filter* includes all matching values in the returned array; if `False`, *Filter* excludes all matching values (or, to put it another way, includes all nonmatching values).

*Compare* optional; CompareMethod enumeration

A constant whose value can be `CompareMethod.Text` or `CompareMethod.Binary` (the default).

## Return Value

A 0-based String array of the elements filtered from *Source*

## Description

The *Filter* function produces an array of matching values from an array of source values that either match or do not match a given filter string. Put another way, individual elements are copied from a source array to a target array if they either match (*Include* is `True`) or do not match (*Include* is `False`) a filter string. A match occurs for an array element if *Match* is a substring of the array element.

## Format Function

## Microsoft.VisualBasic.Strings

```
Format(expression[, style[, dayofweek[, weekofyear]])
```

*expression* required; String/Numeric

Any valid string or numeric expression

*style* optional; String

A valid named or user-defined format expression

*dayofweek* optional; FirstDayOfWeek enumeration

A constant that specifies the first day of the week, as shown in the following table:

| Constant  | Value | Description      |
|-----------|-------|------------------|
| System    | 0     | NLS API setting  |
| Sunday    | 1     | Sunday (default) |
| Monday    | 2     | Monday           |
| Tuesday   | 3     | Tuesday          |
| Wednesday | 4     | Wednesday        |
| Thursday  | 5     | Thursday         |
| Friday    | 6     | Friday           |
| Saturday  | 7     | Saturday         |

`weekofyear` optional; `FirstWeekOfYear` enumeration

A constant that specifies the first week of the year, as shown in the following table:

### First Week of Year Constants

| Constant                        | Value | Description                                                           |
|---------------------------------|-------|-----------------------------------------------------------------------|
| <code>UseSystemDayOfWeek</code> | 0     | Use the NLS API setting                                               |
| <code>FirstJan1</code>          | 1     | Start with the week in which January 1 occurs (default)               |
| <code>FirstFourDays</code>      | 2     | Start with the first week that has at least four days in the new year |
| <code>FirstFullWeek</code>      | 3     | Start with first full week of the year                                |

### Return Value

A string containing the formatted expression

### Description

Allows you to use either predefined or user-defined formats to output string, numeric, and date/time data.

**FormatCurrency,**  
**FormatNumber,FormatPercent**  
**Functions**

**Microsoft.VisualBasic.Strings**

```
FormatCurrency(expression[, NumDigitsAfterDecimal][, _

 IncludeLeadingDigit[, UseParensForNegativeNumbers[, _

 GroupDigits]]])
```

```
FormatNumber(expression[, NumDigitsAfterDecimal][, _

 IncludeLeadingDigit[, UseParensForNegativeNumbers[, _

 GroupDigits]]])
```

```
FormatNumber(expression[, NumDigitsAfterDecimal][, _

 IncludeLeadingDigit[, UseParensForNegativeNumbers[, _

 GroupDigits]]])
```

```
FormatPercent(expression[, NumDigitsAfterDecimal][, _

 IncludeLeadingDigit[, UseParensForNegativeNumbers[, _

 GroupDigits]]])
```

*expression* required; Object

The number or numeric expression to be formatted.

*NumDigitsAfterDecimal* optional; Long

The number of digits the formatted string should contain after the decimal point.

*IncludeLeadingDigit* optional;TriState constant

Indicates whether the formatted string is to have a 0 before floating point numbers between 1 and -1.

*UseParensForNegativeNumbers* optional;TriState constant

Specifies whether parentheses should be placed around negative numbers.

*GroupDigits* optional;TriState constant

Determines whether digits in the returned string should be grouped using the delimiter specified in the computer's regional settings. For example, on English language systems, the value 1000000 is returned as 1,000,000 if *GroupDigits* is True.

## Return Value

String

## Description

Functions used to format currency, numbers, and percentages. The three functions are almost identical. They all take identical arguments. The only difference is that *FormatCurrency* returns a formatted number beginning with the currency symbol specified in the computer's regional settings, *FormatNumber* returns just the formatted number, and *FormatPercent* returns the formatted number followed by a percentage sign (%).

## FormatDateTime Function

## Microsoft.VisualBasic.Strings

```
FormatDateTime(expression[, dateformat])
```

*expression* required; Date

Date variable or literal date

*dateformat* optional; DateFormat enum

Defines the format of the date to return

## Return Value

String representing the formatted date or time

## Description

Formats a date or time expression based on the computer's regional settings.

## GetChar Function

Microsoft.VisualBasic.Strings

```
GetChar(str, index)
```

*str* required; String

The string from which to extract a character

*index* required; Integer

Position of character (1-based)

## Return Value

A Char containing the character at position *index*

## Description

Returns the character that is at position *index* within a given string.

## InStr Function

Microsoft.VisualBasic.Strings

```
InStr(start, string1, string2[, compare])
```

Syntax 1.

```
InStr(string1, string2[, compare])
```

Syntax 2.

*start* required in first syntax; Numeric

The starting position for the search

*string1* required; String

The string being searched

*string2* required; String

The string being sought

*compare* optional; CompareMethod enumeration

The type of string comparison

## Return Value

An Integer indicating the position of the first occurrence of *string2* in *string1*

## Description

Finds the starting position of one string within another.

### InStrRev Function

### Microsoft.VisualBasic.Strings

```
InstrRev(stringcheck, stringmatch[, start[, compare]])
```

*stringcheck* required; String

The string to be searched.

*stringmatch* required; String

The substring to be found within *stringcheck*.

*start* optional; Numeric

The starting position of the search. If no value is specified, *start* defaults to 1.

*compare* optional; CompareMethod enumeration

A constant indicating how *stringcheck* and *stringmatch* should be compared.

## Return Value

Long

## Description

Determines the starting position of a substring within a string by searching from the end of the string to its beginning.

## Join Function

---

See [Join Function](#) entry under [Section 1.11](#).

## LCase Function

Microsoft.VisualBasic.Strings

---

`LCase(value)`

*value* required; String or Char

A valid string expression or a character

### Return Value

String or Char

### Description

Converts a string to lowercase.

## Left Function

Microsoft.VisualBasic.Strings

`Left(str, length)`

*str* required; String

The string to be processed

*length* required; Long

The number of characters to return from the left of the string

### Return Value

String

### Description

Returns a string containing the leftmost *length* characters of *str*.

## Len Function

---

See [Len Function](#) entry under [Section 1.26](#).

## Like Operator

---

```
result = string Like pattern
```

*string* required; String

The string to be tested against *pattern*

*pattern* required; String

A series of characters used by the [Like](#) operator to determine if *string* and *pattern* match

## Return Type

Boolean

## Description

If *string* matches *pattern*, *result* is True; otherwise, *result* is False.

## LSet Function

## Microsoft.VisualBasic.Strings

```
LSet(Source, Length)
```

*Source* required; String

The string to be left aligned

*Length* required; Integer

The length of the returned string

## Return Value

String

## Description

Left aligns a string.

## **LTrim Function**

**Microsoft.VisualBasic.Strings**

---

```
LTrim(str)
```

*str* required; String

A valid string expression

### **Return Value**

String

### **Description**

Removes any leading spaces from *str*.

## **Mid Function**

**Microsoft.VisualBasic.Strings**

```
Mid(str, start[, length])
```

*str* required; String

The expression from which to return a substring

*start* required; Long

The starting position of the substring

*length* optional; Long

The length of the substring

### **Return Value**

String

### **Description**

Returns a substring of a specified length from a given string.

## **Mid Statement**

```
Mid(target, start [, length]) = string
```

*target* required; String

The name of the string variable to be modified

*start* required; Long

The position within *target* at which the replacement commences

*length* optional; Long

The number of characters in *target* to replace

*string* required; String

The string used to replace characters within *target*

## Description

Replaces a section of a string with characters from another string.

## Option Compare Statement

```
Option Compare {Binary | Text}
```

## Description

Used to set the default method for comparing string data. Binary provides for a case sensitive comparison; text provides for a case insensitive comparison in which sort of order is based on the local system's locale settings

## Replace Function

## Microsoft.VisualBasic.Strings

```
Replace(expression, find, replace [, start [, _
 count [, compare]])
```

*expression* required; String

The complete string containing the substring to be replaced

*find* required; String

The substring to be found by the function

*replace* required; String

The new substring to replace *find* in *expression*

*start* optional; Long

The character position in *expression* at which the search for *find* begins

*count* optional; Long

The number of instances of *find* to replace

*compare* optional; CompareMethod constant

The method used to compare *find* with *expression*; its value can be `CompareMethod.Binary` (for case-sensitive comparison) or `CompareMethod.Text` (for case-insensitive comparison)

## Return Value

The return value from *Replace* depends on the parameters you specify in the argument list, as the following table shows:

| If                                      | Return value                                                        |
|-----------------------------------------|---------------------------------------------------------------------|
| <i>expression</i> = ""                  | Zero-length string ("")                                             |
| <i>find</i> = ""                        | Copy of <i>expression</i>                                           |
| <i>replace</i> = ""                     | Copy of <i>expression</i> with all instances of <i>find</i> removed |
| <i>start</i> > Len( <i>expression</i> ) | Zero-length string ("")                                             |
| <i>count</i> = 0                        | Copy of <i>expression</i>                                           |

## Description

Replaces a given number of instances of a specified substring in another string.

### Right Function

### Microsoft.VisualBasic.Strings

`Right(string, length)`

*string* required; String

The string to be processed

*length* required; Integer

The number of characters to return from the right of the string

## Return Value

String

## Description

Returns a string containing the rightmost *length* characters of *string*.

### RSet Function

Microsoft.VisualBasic.Strings

---

`RSet(Source, Length)`

*Source* required; String

The string to be right aligned

*Length* required; Integer

The length of the returned string

## Return Value

String

## Description

Right aligns a string.

### RTrim Function

Microsoft.VisualBasic.Strings

`RTrim(string)`

*string* required; String

A valid string expression

## Return Value

String

## Description

Removes any trailing spaces from *string*.

### Str Function

See [Str Function](#) entry under [Section 1.13](#).

## Spc Function

---

See [Spc Function](#) entry under [Section 1.21](#).

## Space Function

Microsoft.VisualBasic.Strings

---

*Space(number)*

*number* required; Integer

An expression evaluating to the number of spaces required

### Return Value

A String containing *number* spaces

### Description

Creates a string containing *number* spaces.

## Split Function

Microsoft.VisualBasic.Strings

*Split(expression, [delimiter[, limit[, compare]])*

*expression* required; String

A string to be broken up into multiple strings.

*delimiter* optional; String

The character used to delimit the substrings in *expression*.

*limit* optional; Integer

The maximum number of strings to return.

*compare* optional; CompareMethod Constant

The method of comparison. Possible values are `CompareMethod.Binary` (the default) or `CompareMethod.Text`.

## Return Value

A String array containing the substrings of *expression* delimited by *delimiter*

## Description

Parses a single string containing delimited values into an array.

### StrComp Function

Microsoft.VisualBasic.Strings

```
StrComp(string1, string2[, compare])
```

*string1* required; String

Any string expression

*string2* required; String

Any string expression

*compare* optional; CompareMethod constant

Either CompareMethod.Binary or CompareMethod.Text

## Return Value

Integer

## Description

Determines whether two strings are equal and, if not, which of two strings has the greater value.

### StrConv Function

Microsoft.VisualBasic.Strings

```
StrConv(str, conversion[, localeID])
```

*str* required; String

The string expression to convert

*conversion* required; Constant of the VbStrConv enumeration

Constant specifying the type of string conversion.

*localeID* optional; Integer

The locale identifier to use for the conversion

## Return Value

A String converted according to *conversion*

## Description

Performs special conversions on a string.

## StrDup Function

Microsoft.VisualBasic.Strings

---

*StrDup*(*number*, *character*)

*number* required; Integer

The number of times to duplicate the first character in string

*character* required; String, Char, or Object containing a String or Char

The String or Char whose first character is to be duplicated

## Return Value

A String containing the character duplicated the specified number of times

## Description

Returns a string that consists of the first character of *character* duplicated *number* times.

## StrReverse Function

Microsoft.VisualBasic.Strings

*StrReverse*(*expression*)

*expression* required; String

The string whose characters are to be reversed

## Return Value

String

## Description

Returns a string that is the reverse of the string passed to it. For example, if the string `and` is passed to it as an argument, `StrReverse` returns the string `dna`.

### Trim Function

Microsoft.VisualBasic.Strings

---

`Trim(str)`

*str* required; String

Any string expression

### Return Value

String

## Description

Removes both leading and trailing spaces from a given string.

### UCase Function

Microsoft.VisualBasic.Strings

`UCase(value)`

*value* required; String

A valid string expression

### Return Value

String

## Description

Converts a string to uppercase.

### Val Function

See [Val Function](#) entry under [Section 1.13](#).

## VBFixedString Attribute

Microsoft.VisualBasic.VBFixedStringAttribute

---

### Applies to

Field

### Description

Defines a fixed-length string. It is the rough equivalent of the VB 6 declaration:

```
Dim s As String * length
```

It can be used to define fixed-length strings within structures, particularly structures that are to be passed to Win32 API functions, as well as to define fixed-length strings to be written to and read from random access files.

### Constructor

```
New(length)
length Integer
```

The length of the string

### Properties

*Length* Integer

Read-only. The length of the string. Its value is set by the *length* parameter in the class constructor.
